Abstract

First-order temporal logic is a concise and powerful notation, with many potential applications in both Computer Science and Artificial Intelligence. While the full logic is highly complex, recent work on monodic first-order temporal logics has identified important enumerable and even decidable fragments. In this paper, we develop a clausal resolution method for the monodic fragment of first-order temporal logic over expanding domains. We first define a normal form for monodic formulae and show how arbitrary monodic formulae can be translated into the normal form, while preserving satisfiability. We then introduce novel resolution calculi that can be applied to formulae in this normal form and state correctness and completeness results for the method. We illustrate the method on a comprehensive example. The method is based on classical first-order resolution and can, thus, be efficiently implemented.

1. Introduction

In its propositional form, linear, discrete temporal logic has been widely used in the formal specification and verification of reactive systems [18, 15, 12]. Although recognised as a powerful formalism, first-order temporal logic has generally been avoided due to complexity problems (e.g., there is no finite axiom system for general first-order temporal logic). However, recent work by Hodkinson \textit{et al.} [11] has shown that a particular fragment of first-order temporal logic, termed the monodic fragment, has completeness (sometimes even decidability) properties. This breakthrough has led to considerable research activity examining the monodic fragment, in terms of decidable classes, extensions, applications and mechanisation, etc.

Concluding the mechanisation of monodic temporal logics, general tableau and resolution calculi have already been defined, in [13] and [5, 3], respectively. However, neither of these is particularly practical: the tableau method requires representation of all possible first-order models, while the resolution method requires the maximal combination of all temporal clauses. In this paper, we focus on an important subclass of temporal models, having a wide range of applications, for example in spatio-temporal logics [21, 10] and temporal description logics [1], namely those models that have expanding domains. In such models, the domains over which first-order terms range can increase at each temporal step. The focus on this class of models allows us to produce a simplified clausal resolution calculus, termed a fine-grained calculus, which is more amenable to efficient implementation.

Thus, we will define the expanding domain monodic fragment, a fine-grained resolution calculus, and provide completeness results for the fine-grained calculus relative to the completeness of the general resolution calculus [6]. A number of examples will be given, showing how the fine-grained calculus works in practice and, finally, conclusions and future work will be provided.

2. First-Order Temporal Logic

First-Order (discrete linear time) Temporal Logic, FOTL, is an extension of classical first-order logic with operators that deal with a linear and discrete model of time (isomorphic to \(\mathbb{N}\), and the most commonly used model of time). The first-order temporal language is constructed in a standard way [9, 11] from: predicate symbols \(P_0, P_1, \ldots\); each of which is of some fixed arity (null-ary predicate symbols are called propositions); individual variables \(x_0, x_1, \ldots\); individual constants \(c_0, c_1, \ldots\); booleans operators \(\land, \neg, \lor, \Rightarrow, \equiv\), true (‘true’), false (‘false’); quantifiers \(\forall, \exists\); together with temporal operators \(\square\) (‘always in the future’),
\(\Diamond\) (‘sometime in the future’), \(\Box\) (‘at the next moment’), \(U\) (until), and \(W\) (weak until). There are no function symbols or equality in this FOTL language, but it does contain constants. For a given formula, \(\phi\), \(\text{const}(\phi)\) denotes the set of constants occurring in \(\phi\). We write \(\phi(x)\) to indicate that \(\phi(x)\) has at most one free variable \(x\) (if not explicitly stated otherwise).

Formulæ in FOTL are interpreted in first-order temporal structures of the form \(M = (D_n, I_n)\), \(n \in \mathbb{N}\), where every \(D_n\) is a non-empty set such that whenever \(n < m\, D_n \subseteq D_m\), and \(I_n\) is an interpretation of predicate and constant symbols over \(D_n\). We require that the interpretation of constants is rigid. Thus, for every constant \(c\), and all moments of time \(i, j \geq 0\), we have \(I_i(c) = I_j(c)\).

A (variable) assignment \(a\) is a function from the set of individual variables to \(\cup_{n \in \mathbb{N}} D_n\). (This definition implies that variable assignments are rigid as well.) We denote the set of all assignments by \(\mathfrak{V}\).

For every moment of time \(n\), there is a corresponding first-order structure, \(M_n = (D_n, I_n)\); the corresponding set of variable assignments \(\mathfrak{V}_n\) is a subset of the set of all assignments, \(\mathfrak{V}_n = \{ a \in \mathfrak{V} \mid a(x) \in D_n \text{ for every variable } x\}\); clearly, \(\mathfrak{V}_n \subseteq \mathfrak{V}_m\) if \(n < m\). Intuitively, FOTL formulæ are interpreted in sequences of worlds, \(M_0, M_1, \ldots\) with truth values in different worlds being connected via temporal operators.

The truth relation \(M_n \models \phi\) in a structure \(M\), only for those assignments \(a\) that satisfy the condition \(a \in \mathfrak{V}_n\), is defined inductively in the usual way under the following understanding of temporal operators:

\[
\begin{align*}
M_n \models \Box \phi & \iff M_{n+1} \models \phi; \\
M_n \models \Diamond \phi & \iff \text{there exists } m \geq n \text{ such that } M_m \models \phi; \\
M_n \models \Box \Diamond \phi & \iff \text{for all } m \geq n, M_m \models \phi; \\
M_n \models (\phi \land \psi) & \iff \text{there exists } m \geq n, \text{ such that } M_m \models \psi, \text{ and for all } i \in \mathbb{N}, n \leq i < m \text{ implies } M_i \models \Diamond \phi; \\
M_n \models (\phi \lor \psi) & \iff M_n \models (\phi \land \psi) \text{ or } M_n \models \Box \phi.
\end{align*}
\]

\(M\) is a model for a formula \(\phi\) (or \(\phi\) is true in \(M\)) if there exists an assignment \(a\) such that \(M_0 \models \phi\). A formula is satisfiable if it has a model. A formula is valid if it is true in any temporal structure under any assignment.

The models introduced above are known as models with expanding domains. Another important class of models consists of models with constant domains in which the class of first-order temporal structures, where FOTL formulæ are interpreted, is restricted to structures \(M = (D_n, I_n)\), \(n \in \mathbb{N}\), such that \(D_i = D_j\) for all \(i, j \in \mathbb{N}\). The notions of truth and validity are defined similarly to the expanding domain case.

It is known [19] that satisfiability over expanding domains can be reduced to satisfiability over constant domains.

**Example 1** The formula \(\forall x P(x) \land \Box (\forall x P(x) \Rightarrow \Box \forall x Q(x)) \land \Box \neg Q(c)\) is unsatisfiable over both expanding and constant domains; the formula \(\forall x P(x) \land \Box (\forall x P(x) \Rightarrow \Box Q(x)) \land \Box \neg Q(c)\) is unsatisfiable over constant domains but has a model with an expanding domain.

This logic is complex. It is known that even "small" fragments of FOTL, such as the two-variable monadic fragment (all predicates are unary), are not recursively enumerable [16, 11]. However, the set of valid monadic formulæ is known to be finitely axiomatisable [20].

**Definition 1** An FOTL-formula \(\phi\) is called monodic if any subformulæ of the form \(\mathcal{T}\psi\), where \(\mathcal{T}\) is one of \(\Box, \Diamond, \neg\) (or \(\psi_1 \mathcal{T} \psi_2\), where \(\mathcal{T}\) is one of \(U, W\)), contains at most one free variable.

**3. Divided Separated Normal Form (DSNF)**

**Definition 2** A temporal step clause is a formula either of the form \(p \Rightarrow \Box l\), where \(p\) is a proposition and \(l\) is a propositional literal, or \((P(x) \Rightarrow \Box M(x))\), where \(P(x)\) is a unary predicate and \(M(x)\) is a unary literal. We call a clause of the the first type an (original) ground step clause, and of the second type an (original) non-ground step clause.

**Definition 3** An unconditional eventuality monodic temporal problem in Divided Separated Normal Form (DSNF) is a quadruple \(\langle U, I, S, L, \rangle\), where

1. the universal part, \(U\), is given by a set of arbitrary closed first-order formulæ;
2. the initial part, \(I\), is, again, given by a set of arbitrary closed first-order formulæ;
3. the step part, \(S\), is given by a set of original (ground and non-ground) temporal step clauses; and
4. the eventuality part, \(L\), is given by a set of unconditional eventuality clauses of the form \(\Diamond L(x)\) (a non-ground eventuality clause) and \(\neg l\) (a ground eventuality clause), where \(l\) is a propositional literal and \(L(x)\) is a unary non-ground literal.

Note that, in a monodic temporal problem, we do not allow two different temporal step clauses with the same left-hand sides. In what follows, we will not distinguish between a finite set of formulæ \(X\) and the conjunction \(\bigwedge X\) of formulæ within the set. With each unconditional eventuality monodic temporal problem, we associate the formula

\[I \land \Box U \land \Box \forall x S \land \Box \forall x L.\]

Now, when we talk about particular properties of a temporal problem (e.g., satisfiability, validity, logical consequences etc) we mean properties of the associated formulæ.
Arbitrary monodic FOTL-formulae can be transformed into DSNF in a satisfiability equivalence preserving way using a renaming technique replacing non-atomic subformulae with new propositions and removing all occurrences of the $U$ and $W$ operators [9, 5].

4. Completeness Calculus

A resolution-like procedure for the monodic fragment over constant domains has been introduced in [5]. Although satisfiability over expanding domains can be reduced to satisfiability over constant domains [19], it has been proved in [6] that a simple modification of the procedure can be directly applied to the expanding domain case. We sketch the monodic temporal resolution system here to make the paper self-contained. We use this 'completeness calculus' to show relative completeness of the calculus presented in the next section. More details on the completeness calculus, as well as proofs of the properties stated below, can be found in [5] and [6] for the constant and expanding domain cases, respectively.

Let $P$ be a monodic temporal problem, and let

$$P_i(x) \Rightarrow \Box M_i(x), \ldots, P_k(x) \Rightarrow \Box M_k(x)$$

be a subset of the set of its original non-ground step clauses. Then formulae of the form

$$P_{ij}(c) \Rightarrow \Box M_{ij}(c),$$
$$\exists x \bigvee_{j=1}^{n-1} P_{ij}(x) \Rightarrow \Box \exists x \bigvee_{j=1}^{n-1} M_{ij}(x),$$
$$\Box \forall x \bigvee_{j=1}^{n-1} P_{ij}(x) \Rightarrow \Box \forall x \bigvee_{j=1}^{n-1} M_{ij}(x)$$

are called derived step clauses, where $c \in \text{const}(P)$. (Formulae of the form (2) and (3) are called $e$-derived step clauses.) Note that formulae of the form (2) and (3) are logical consequences of (1) in the expanding domain case; while formulae of the form (2), (3), and (4) are logical consequences of (1) in the constant domain case. As Example 1 shows, (4) is not a logical consequence of (1) in the expanding domain case.

Let $\Phi_1 \Rightarrow \Box \Psi_1, \ldots, \Phi_n \Rightarrow \Box \Psi_n$ be a set of derived (e-derived) step clauses or original ground step clauses. Then $\bigwedge_{i=1}^{n} \Phi_i \Rightarrow \Box \bigwedge_{i=1}^{n} \Psi_i$ is called a merged derived step clause (and merged $e$-derived step clause, resp.).

Let $A \Rightarrow \Box B$ be a merged derived (e-derived) step clause, let $P_i(x) \Rightarrow \Box M_i(x), \ldots, P_k(x) \Rightarrow \Box M_k(x)$ be a subset of the original step clauses, and let $A(x) = A \wedge \bigwedge_{i=1}^{k} P_i(x), B(x) = B \wedge \bigwedge_{i=1}^{k} M_i(x)$. Then $\forall x(A(x) \Rightarrow \Box B(x))$ is called a full merged step clause (full $e$-merged step clause, resp.).

Let $P$ be a monodic temporal problem, $P^c = P \cup \{\Box L(c) \mid \Box L(x) \in E, c \in \text{const}(P)\}$ is the constant flooded form of $P$. Evidently, $P^c$ is satisfiability equivalent to $P$.

We present now two calculi, $\mathcal{J}_c$ and $\mathcal{J}_e$, aimed at the constant and expanding domain cases, respectively. The inference rules of these calculi coincide; the only difference is in the merging operation. The calculus $\mathcal{J}_e$ utilizes merged derived and full merged step clauses; whereas $\mathcal{J}_c$ utilizes merged e-derived and full e-merged step clauses.

**Inference Rules.**

- **Step resolution rule** w.r.t. $U$: $A \Rightarrow \Box B$, where $U \cup \{B\} \vdash \bot$.
- **Initial termination rule** w.r.t. $U$: The contradiction $\bot$ is derived and the derivation is (successfully) terminated if $U \cup I \vdash \bot$.
- **Eventuality resolution rule** w.r.t. $U$:

$$\forall x(A_1(x) \Rightarrow \Box (B_1(x)))$$
$$\vdots$$
$$\forall x(A_n(x) \Rightarrow \Box (B_n(x)))$$

$$\forall x \bigwedge_{i=1}^{n} \neg A_i(x)$$

where $\forall x(A_i(x) \Rightarrow \Box B_i(x))$ are full merged (full e-merged) step clauses such that for all $i \in \{1, \ldots, n\}$, the loop side conditions $\forall x(U \wedge B_i(x) \Rightarrow \neg L(x))$ and $\forall x(U \wedge B_i(x) \Rightarrow \bigvee_{j=1}^{n} A_j(x))$ are both valid.

The set of full merged (full e-merged) step clauses, satisfying the loop side conditions, is called a **loop in** $\Box L(x)$ and the formula $\bigvee_{j=1}^{n} A_j(x)$ is called a **loop formula**.

- **Ground eventuality resolution rule** w.r.t. $U$:

$$A_1 \Rightarrow \Box B_1, \ldots, A_n \Rightarrow \Box B_n$$
$$\bot \quad \bigvee_{i=1}^{n} \neg A_i$$

where $\bigwedge_{i=1}^{n} A_i \Rightarrow \Box B_i$ are merged derived (e-derived) step clauses such that the loop side conditions $U \wedge B_i \vdash \bot$.

---

1. $A \Rightarrow \Box B$ and $A \Rightarrow \Box B$ denote here merged derived (e-derived) step clauses, $\forall x(A(x) \Rightarrow \Box (B_i(x)))$ and $\forall x(A_i(x) \Rightarrow \Box (B_i(x)))$ denote full merged (full e-merged) step clauses, and $U$ denotes the (current) universal part of the problem.

2. In the case $U \vdash \neg L(x)$, the degenerate clause, $\neg true \Rightarrow \Box true$, can be considered as a premise of this rule; the conclusion of the rule is then $\neg true$ and the derivation successfully terminates.
then there exists a successfully terminating derivation in $\mathcal{I}_e$.

A derivation is a sequence of universal parts, $\mathcal{U} = \mathcal{U}_0 \subseteq \mathcal{U}_1 \subseteq \mathcal{U}_2 \subseteq \ldots$, extended little by little by the conclusions of the inference rules. Successful termination means that the given problem is unsatisfiable. The $I$, $S$ and $E$ parts of the temporal problem are not changed in a derivation.

Theorem 1 (see [5], theorems 2 and 3) The rules of $\mathcal{I}_e$ preserve satisfiability over constant domains. If a monodic temporal problem $P$ is unsatisfiable over constant domains, then there exists a successfully terminating derivation in $\mathcal{I}_c$ from $P_c$.

Theorem 2 (see [6], theorems 2 and 3) The rules of $\mathcal{I}_e$ preserve satisfiability over expanding domains. If a monodic temporal problem $P$ is unsatisfiable over expanding domains, then there exists a successfully terminating derivation in $\mathcal{I}_e$ from $P_c$.

Example 2 The need for constant flooding can be demonstrated by the following example. None of the rules of temporal resolution can be applied directly to the (unsatisfiable) temporal problem given by

\[
I = \{ P(c) \}, \quad S = \{ q \rightarrow \square q \}, \quad \mathcal{U} = \{ q \equiv P(c) \}, \quad E = \{ \lozenge \neg P(x) \}.
\]

If, however, we add to the problem an eventuality clause $\lozenge l$ and a universal clause $l \rightarrow \neg P(c)$, the step clause $q \Rightarrow \square q$ will be a loop in $\lozenge l$, and the eventuality resolution rule would derive $\neg \text{true}^3$.

5. Fine-Grained Resolution for the Expanding Domain Case

The main drawback of the calculi introduced in the previous section is that the notion of a merged step clause is quite involved and the search for appropriate merging of simpler clauses is computationally hard. Finding sets of such full merged step clauses needed for the temporal resolution rule is even more difficult.

From now on we focus on the expanding domain case. This is simpler firstly because merged e-derived step clauses are simpler (formulae of the form (4) do not contribute to them) and, secondly, because conclusions of all inference rules of $\mathcal{I}_e$ are first-order clauses.

We now introduce a calculus where the inference rules of $\mathcal{I}_e$ are refined into smaller steps, more suitable for effective implementation. First, we concentrate on the implementation of the step resolution inference rule; then we show how to effectively find premises for the eventuality resolution rule by means of step resolution.

The calculus is inspired by the following consideration: Suppose that $\mathcal{I}_e$ applies the step resolution rule to a merged e-derived step clause $A \Rightarrow \square B$. The rule can be applied if $B \cup \mathcal{U} \not\vdash \bot$, and this fact can be established by a first-order resolution procedure (that would skolemise the universal part). Then the conclusion of the rule, $\neg A$, is added to $\mathcal{U}$ resulting in a new universal part $\mathcal{U}'$. Suppose that the step resolution rule is applied to another merged e-derived step clause, $A' \Rightarrow \square B'$. The side condition, $B' \cup \mathcal{U} \vdash \bot$, again can be checked by a first-order resolution procedure. Since we never add new existential formulæ, $\mathcal{U}'$ can be skolemised in exactly the same way as $\mathcal{U}$. Therefore, we can actually keep $\mathcal{U}$ in clausal form.

Note further that we are not only going to check side conditions for the rules of the $\mathcal{I}_e$ by means of first-order resolution but also search for clauses to merge at the same time.

Fine-grained resolution might generate additional step clauses of the form

\[
C \Rightarrow \square D.
\]

Here, $C$ is a conjunction of propositions, unary predicates of the form $P(x)$, and ground formulæ of the form $P(c)$, where $P$ is a unary predicate symbol and $c$ is a constant occurring in an originally given problem; $D$ is a disjunction of arbitrary literals.

Let $P$ be a constant flooded temporal problem; the set of clauses $S(P)$, called the result of preprocessing, consists of step clauses from $P$ and

1. For every original non-ground step clause

\[
P(x) \Rightarrow \square Q(x)
\]

and every constant $c \in \text{const}(P)$, the clause

\[
P(c) \Rightarrow \square Q(c)
\]

is in $S(P)$.

2. Clauses obtained by classification of the universal and initial parts, as if there is no connection with temporal logic at all, are in $S(P)$. The resulting clauses are called universal clauses and initial clauses resp. Originally, universal and initial clauses do not have common Skolem constants and functions. Initial and universal clauses are kept separately.

In sections 5.1 and 5.2, we assume that a given problem is preprocessed.

\[3\text{Note that the non-ground eventuality } \lozenge \neg P(x) \text{ is not used. It was shown in [4] that if all step clauses are ground, for constant flooded problems we can neglect non-ground eventualities.}\]
5.1. Fine-grained step resolution

Fine-grained step resolution consists of a set of deduction and simplification rules. We implicitly assume that different premises and conclusion of the deduction rules have no variables in common; variables are renamed if necessary.

Deduction rules

1. Arbitrary (first-order) resolution between universal clauses. The result is a universal clause.

2. Arbitrary (first-order) resolution between initial and universal clauses (or just between initial clauses). The result is an initial clause.

3. Fine-grained (restricted) step resolution

\[
\frac{C_1 \Rightarrow \circ (D_1 \lor L) \quad C_2 \Rightarrow \circ (D_2 \lor \neg M)}{(C_1 \land C_2) \sigma \Rightarrow \circ (D_1 \lor D_2) \sigma},
\]

where \(C_1 \Rightarrow \circ (D_1 \lor L)\) and \(C_2 \Rightarrow \circ (D_2 \lor \neg M)\) are step clauses and \(\sigma\) is an mgu of the literals \(L\) and \(M\) such that \(\sigma\) does not map variables from \(C_1\) or \(C_2\) into a constant or a functional term.\(^4\)

\[
\frac{C_1 \Rightarrow \circ (D_1 \lor L) \quad D_2 \lor \neg N}{C_1 \sigma \Rightarrow \circ (D_1 \lor D_2) \sigma},
\]

where \(C_1 \Rightarrow \circ (D_1 \lor L)\) is an step clause, \(D_2 \lor \neg N\) is a universal clause, and \(\sigma\) is an mgu of the literals \(L\) and \(N\) such that \(\sigma\) does not map variables from \(C_1\) into a constant or a functional term.

4. Right factor

\[
\frac{C \Rightarrow \circ (D \lor L \lor M)}{C \sigma \Rightarrow \circ (D \lor L) \sigma},
\]

where \(\sigma\) is an mgu of the literals \(L\) and \(M\) such that \(\sigma\) does not map variables from \(C\) into a constant or a functional term.

5. Left factor

\[
\frac{(C \land L \land M) \Rightarrow \circ D}{(C \land L) \sigma \Rightarrow \circ D \sigma},
\]

where \(\sigma\) is an mgu of the literals \(L\) and \(M\) such that \(\sigma\) does not map variables from \(C\) into a constant or a functional term.

6. Clause conversion

a step clause of the form \(C \Rightarrow \circ \text{false}\) is rewritten into the universal clause \(\neg C\).

---

Deletion rules

1. First-order deletion: (first-order) subsumption and tautology deletion in universal clauses; subsumption and tautology deletion in initial clauses; subsumption of initial clauses by universal clauses (but not vice versa).

2. Temporal deletion:

A universal clause \(D_2\) subsumes a step clause \(C_1 \Rightarrow \circ D_1\) if \(D_2\) subsumes \(D_1\) or \(D_2\) subsumes \(\neg C_1\).

A step clause \(C_1 \Rightarrow \circ D_1\) subsumes a step clause \(C_2 \Rightarrow \circ D_2\) if there exists a substitution \(\sigma\) such that \(\sigma\) does not map variables from \(C_1\) into a functional term. A step clause \(C \Rightarrow \circ D\) is a tautology if \(D\) is a tautology. (Note that, since we do not have negative occurrences to the left-hand side of step rules, \(C\) cannot be false). Tautologies are deleted.

We adopt the terminology from [2]. A (linear) proof by fine-grained resolution of a clause \(C\) from a set of clauses \(S\) is a sequence of sets of clauses \(S_0, S_1, \ldots\) such that every \(S_{i+1}\) differs from \(S_i\) by either adding the conclusion of a deduction rule or else deleting a clause by a deletion rule. We say that a clause \(C\) is derived by fine-grained resolution from \(S_0\) if \(C \in S_i\) for some \(i\).

Note 1 Fine-grained step resolution without the restriction on substitutions would, certainly, lead to unsoundness: It would prove, for example, “unsatisfiability” of the monodic problem given by \(\forall x \forall y. P(x, y) \land \forall x. Q(x) \land \neg Q(1, 2)\) and \(S = \{s1 \land -Q(1), s2 \land -Q(2)\}\). (After skolemisation, \(\forall x y\). \(P(x, y) \land Q(x)\), then unrestricted resolution would derive \(s1 \land s2, \neg P(c)\) from \(s1, s2\), and \(s3\).)

Example 3 It might seem that the restriction on mgus is too strong and destroys completeness of the calculus, for example, that under this restriction it is not possible to deduce a contradiction from the following (unsatisfiable) temporal problem

\[
I = \{\forall x P(x)\}, \quad U = \{\neg Q(c)\},
\]

\(S = \{P(x) \Rightarrow \circ Q(c)\}, \quad E = \emptyset\).

Note, however, that we apply our calculus to the preprocessed problem which contains an additional step clause

\[
P(c) \Rightarrow \circ Q(c).
\]

A formal statement of completeness follows.

---

\(^4\)This restriction justifies skolemisation: Skolem constants and functions do not ‘sneak’ in the left-hand side of step rules, and, hence, Skolem constants from different moments of time do not mix.

\(^5\)Here, and further, \(\neg \{L_i(x) \land \ldots \land L_n(x)\}\) abbreviates \(\neg L_i(x) \lor \ldots \lor \neg L_n(x)\).
A clause of the form $C \Rightarrow \bigcirc \text{false}$, where $C$ is of the same form as in (5), is called a final clause.

**Lemma 3** Let $\mathcal{P} = \langle \mathcal{U}, I, S, \mathcal{E} \rangle$ be a monodic temporal problem and $\mathcal{S} = S(\mathcal{P})$ be the result of preprocessing. Let $C \Rightarrow \bigcirc \text{false}$ be an arbitrary final clause derived by fine-grained step resolution from $\mathcal{S}$. Then there exists a derivation $\mathcal{U} = \mathcal{U}_0 \subseteq \mathcal{U}_1 \subseteq \ldots$ by the step resolution rule of $\mathcal{S}$ and a merged e-derived step rule $\mathcal{A} \Rightarrow \bigcirc \mathcal{B}$ such that $\mathcal{B} \cup \mathcal{U}_i \vdash \bot$, for some $i \geq 0$, and $\mathcal{A} = \exists \mathcal{C}$, where $\exists$ means existential quantification over all free variables.

**Proof** (Sketch). Since $C \Rightarrow \bigcirc \text{false}$ is derivable, there exists its proof $\Gamma$ by fine-grained resolution. We prove the lemma by induction on the number of applications of the clause conversion rule in $\Gamma$. Suppose we proved the lemma for proofs containing less than $n$ applications of the clause conversion rule, and let $\Gamma$ contains $n$ such applications. Then every conclusion of the clause conversion rule is also a conclusion by the step resolution rule of $\mathcal{S}$. It can be shown that both the induction basis and induction step follow from the following claim.

**Claim**. Let $\Delta$ be a proof of $C \Rightarrow \bigcirc \text{false}$ by the rules of fine-grained resolution, except the clause conversion rule, from a set of step clauses $\mathcal{S}$ and a set of universal clauses $\mathcal{U}$. Then there exists a merged e-derived step rule $\mathcal{A} \Rightarrow \bigcirc \mathcal{B}$ such that $\mathcal{B} \cup \mathcal{U} \vdash \bot$ and $\mathcal{A} = \exists \mathcal{C}$.

Let

$$
\begin{align*}
\{ P_i(x_i) & \Rightarrow \bigcirc Q_i(x_i) \mid i = 1 \ldots K \\
\{ p_i & \Rightarrow \bigcirc q_i \mid i = 1 \ldots L \}
\end{align*}
$$

be the set of all step clauses from $\mathcal{S}$ involved in $\Delta$ where $p_i \Rightarrow \bigcirc q_i$ denotes either a ground step clause, or an e-derived step-clause of the form (6) added by preprocessing (w.l.o.g., we assumed that all the variables $x_1, \ldots, x_K$ are pairwise distinct). We assume that $\Delta$ is tree-like, that is, no clause in $\Delta$ is used more than once as an assumption for an inference rule; we may make copies of the clauses in $\Delta$ in order to make it tree-like.

Note that (by accumulating the mgus used in the proof) it is possible to construct a finite set of instances of these clauses (and universal clauses) such that there exists a tree-like proof of $C \Rightarrow \bigcirc \text{false}$ from this new set of clauses and all mgus used in the proof are empty$^5$. That is, there exist substitutions $\{ \sigma_{ij} \mid i = 1 \ldots K, j = 1 \ldots s_i \}$ such that

$$
\begin{align*}
\{ P_i(x_i) \sigma_{ij} & \Rightarrow \bigcirc Q_i(x_i) \sigma_{ij} \mid i = 1 \ldots K, j = 1 \ldots s_i \\
\{ p_i & \Rightarrow \bigcirc q_i \mid i = 1 \ldots L \}
\end{align*}
$$

(7)

Note further (induction) that due to our restriction on the step resolution rule, for any $i, j$, the substitution $\sigma_{ij}$ maps $x_i$ into a free variable.

Let us group the instances of the step clauses according to the value of the substitutions. We introduce an equivalence relation $\Sigma$ on the clauses from (7) as follows: For every $i, j, i', j'$ we have $P_i(x_i) \sigma_{ij} \Rightarrow \bigcirc Q_i(x_i) \sigma_{ij}, P_i(x_{i'}) \sigma_{i'j'} \Rightarrow \bigcirc Q_i(x_{i'}) \sigma_{i'j'} \in \Sigma$ iff $x_i \sigma_{ij} = x_{i'} \sigma_{i'j'}$ (it can be easily checked that $\Sigma$ is indeed an equivalence relation). Let $M$ be the number of equivalence classes of (7) by $\Sigma$; let $I_l$ be the set of indexes of the $l$-th equivalence class (we refer to clauses from (7) by indexes of the corresponding substitutions).

Let $C_l = \bigwedge_{(i,j) \in I_l} P_i(x_i) \sigma_{ij}$, for every $l, 1 \leq l \leq M$; let $C_0 = \bigwedge_{i=1}^n p_i$. Note that $C = \bigwedge_{l=1}^M C_l \land C_0$ and this partition of $C$ is disjoint. Let $D_l = \bigwedge_{(i,j) \in I_l} Q_i(x_i) \sigma_{ij}$, let $D_0 = \bigwedge_{i=1}^n q_i$, let $D = \bigwedge_{l=1}^M D_l \land D_0$. Note that $\forall D \land \bigwedge \bot$. Note further that if we replace the free variable of $D_l$ with a fresh constant, $c_l$, there still exists a refutation from $\bigwedge_{l=1}^M D(c_l) \land D_0$ and universal clauses (with mgus applied to universal and intermediate clauses only). It follows that $\bigwedge_{l=1}^M \exists x D(x) \land D_0 \land \bigwedge \bot$. It suffices to note that $(\bigwedge_{l=1}^M \exists x C_l(x) \land C_0) \Rightarrow \bigcirc (\bigwedge_{l=1}^M \exists x D_l(x) \land D_0)$ is a merged e-derived step clause.

**Lemma 4** Let $\mathcal{P} = \langle \mathcal{U}, I, S, \mathcal{E} \rangle$ be a monodic temporal problem and $\mathcal{S} = S(\mathcal{P})$ be the result of preprocessing. Let $\mathcal{U} = \mathcal{U}_0 \subseteq \mathcal{U}_1 \subseteq \ldots$ be a derivation by the step resolution rule of $\mathcal{S}$. Let $\mathcal{A} \Rightarrow \bigcirc \mathcal{B}$ be a merged e-derived step rule such that $\mathcal{B} \cup \mathcal{U}_i \vdash \bot$, for some $i \geq 0$. Then there exists a final clause $C \Rightarrow \bigcirc \text{false}$, derived by fine-grained resolution from $\mathcal{S}$, such that $\mathcal{A} \Rightarrow \exists \mathcal{C}$.

**Proof** (Sketch). As in the proof of the previous lemma, it suffices to prove that under conditions of the lemma there exists a proof of a final clause $C \Rightarrow \bigcirc \text{false}$ from the set of step clauses from $\mathcal{S}$ and the (current) universal part, $\mathcal{U}_i$, by the rules of fine-grained resolution, except the clause conversion rule, such that $\mathcal{A} \Rightarrow \exists \mathcal{C}$.

Since $\mathcal{B} \cup \mathcal{U}_i \vdash \bot$, by the definition of a merged e-derived step clause, there exists a set of instances of step clauses

$$
\begin{align*}
\{ P_l(c_l) & \Rightarrow \bigcirc Q_l(c_l) \mid i = 1 \ldots K, j = 1 \ldots s_i \\
\{ p_l & \Rightarrow \bigcirc q_l \mid i = 1 \ldots L \}
\end{align*}
$$

$^5$The condition that premises of the non-ground binary resolution rule should be variable disjoint may be violated here; note, however, that this condition is needed for completeness, not correctness.
where \(c_1, \ldots, c_K\) are new (Skolem) constants, such that 
\[ \bigwedge_{i=1}^{K} \bigwedge_{j=1}^{L} Q_j(c_i) \land \bigwedge_{i=1}^{L} q_i \land \mathcal{U} \not\vdash \perp \] (again, as in the proof of Lemma 3, \(p_I \not\Rightarrow \bigcirc q_i\) denotes either an original ground step clause or a clause of the form (6) added by the preprocessing).

Let \(\Delta\) be a (first-order) resolution proof of \(\perp\) from \(\mathcal{U}_i\) and the following set of clauses \(\{Q_j(c_i) \mid i = 1 \ldots K, j = 1 \ldots s_i\} \cup \{q_i \mid i = 1 \ldots L\}\). Let \(\{Q_j(c_i) \mid (i, j) \in I\} \cup \{q_i \mid i \in J\}\), for some sets of indexes \(I\) and \(J\), be its subset containing all clauses involved in \(\Delta\) (and only the clauses involved in \(\Delta\)). Then there exists a proof \(\Gamma\) by fine-grained step resolution from

\[
\begin{align*}
\{P_j(c_i) \Rightarrow \bigcirc Q_j(c_i) \mid (i, j) \in I\} \\
\{p_1 \Rightarrow \bigcirc q_1 \mid i \in J\}
\end{align*}
\]

(and universal clauses) of a final clause \(C \Rightarrow \bigcirc \text{false}\), where

\[ C = \bigwedge_{(i, j) \in I} P_j(c_i) \land \bigwedge_{i \in J} p_i. \]

We assume, for simplicity of the proof, that the lifting theorem (cf. e.g. [14]) holds for \(\Delta\), that is, there exists a non-ground (first-order) refutation \(\Delta'\) from \(\{Q_j(c_i) \mid (i, j) \in I\} \cup \{q_i \mid i \in J\}\), such that \(\Delta \leq_s \Delta'\) in the terminology of [14]: Every clause \(C'_j\) of \(\Delta'\) is a generalisation of the corresponding clause \(C_i\) of \(\Delta\).

It can be seen that the lifting theorem can be transferred to fine-grained inferences, and there exists a proof \(\Gamma'\) from the set of original step clauses

\[
\begin{align*}
\{P_j(x_i) \Rightarrow \bigcirc Q_j(x_i) \mid (i, j) \in I\} \\
\{p_1 \Rightarrow \bigcirc q_1 \mid i \in J\}
\end{align*}
\]

(and universal clauses) of a final clause \(C' \Rightarrow \bigcirc \text{false}\) such that \(\Gamma' \geq_s \Gamma\), that is, every intermediate clause \(C'_j \Rightarrow \bigcirc D'_i\) from \(\Gamma'\) is a generalisation of a corresponding clause from \(\Gamma\). (The only difficulty is to ensure the requirement on mgus imposed by our inference system. Note that none of the (Skolem) constants \(c_1, \ldots, c_K\) occurs in \(\Gamma'\). If, in the proof \(\Gamma'\), a constant or a functional term was substituted into a variable occurring into the left-hand side of a clause, this clause would not be a generalisation of any clause from \(\Gamma\).) This implies the conclusion of the lemma.

Lemma 3 ensures soundness of fine-grained step resolution. Lemma 4 says that the conclusion of an application of the clause conversion rule, \(\neg C\), subsumes the conclusion of an application of the step resolution rule of \(\mathcal{J}_n, \neg A\).

**Theorem 5** The calculus consisting of the rules of fine-grained step resolution, together with the (both ground and non-ground) eventual resolution rule, is sound and complete for the monodic fragment over expanding domains.

**Note 2** The proof of completeness given above might be hard to fulfil in the presence of various refinements of resolution and or redundancy deletion. As a remedy, we suggest considering constrained calculi, like e.g. resolution over constrained clauses with constraint inheritance. It is known that such inference systems are complete and moreover compatible with redundancy elimination rules and many (liftable) refinements (see e.g. [17], theorems 5.11 and 5.12, subsections 5.4 and 5.5, resp.). Here we take into account that there are no clauses with equality, and therefore all sets are well-constrained in the terminology of [17].

Then instead of ground clauses of the form

\[ P_j(c_i) \Rightarrow \bigcirc Q_j(c_i) \]

we consider their constrained representations

\[ P_j(x_i) \Rightarrow \bigcirc Q_j(x_i) \cdot \{x_i = c_i\} \]

Recall that in accordance with the semantics of constrained clauses, a clause \(C \cdot T\) represents the set of all ground instances \(C\sigma\) where \(\sigma\) is a solution of \(T\). In our case, there is exactly one solution of \(x_i = c_i\) given by the substitution \(\{x_i \mapsto c_i\}\). So, the semantics of

\[ P_j(x_i) \Rightarrow \bigcirc Q_j(x_i) \cdot \{x_i = c_i\} \]

is just

\[ P_j(c_i) \Rightarrow \bigcirc Q_j(c_i) \]

So, all clauses originating from the universal part have empty constraints and all temporal clauses have constraints defined above, and there exists a non-ground proof of a constrained final clause with constraint inheritance. Note that the (Skolem) constants \(c_1, \ldots, c_K\) may only occur in constraints but not in clauses themselves. It suffices to note that in this case inferences with constraint inheritance admit only two kinds of substitutions into \(x_i\): either \(\{x_i \mapsto c_i\}\) (however it is impossible because \(c_i\) occurs only in constraints), or \(\{x_i \mapsto x_j\}\) where \(x_j\) is bound by the same constraint \(\{x_j = c_i\}\). The case of matching \(x_i\) and \(y\) where \(y\) originates from the universal part is solved by the substitution \(\{y \mapsto x_i\}\). A non-ground inference of a final clause, satisfying the conditions on substitutions in the fine-grained resolution rules, can be extracted from this constrained proof implying, thus, the conclusion of the lemma 4.

**5.2. Loop search**

Next we use fine-grained step resolution to find the appropriate set of full e-merged clauses to apply the (ground or non-ground) eventual resolution rule. It has been noticed in [5] that in order to effectively find a loop in \(L(x) \in \mathcal{E}\), given a formula with one free variable \(\Phi(x)\) we have to be able to find the set of all full e-merged clauses of the form

\[ \forall x(\mathcal{A}(x) \Rightarrow \bigcirc B(x)) \]  

such that the formula

\[ \forall x(B(x) \land \mathcal{U} \Rightarrow \Phi(x)) \]
Figure 1. Breadth-first search using fine-grained step resolution.

Lemma 7 Let $S$ be a set of universal and step clauses, and let $\forall x (A(x) \Rightarrow \bigcirc B(x))$ be a full e-merged (from $S$) step clause such that $\forall x (B(x) \land U \Rightarrow \Phi(x))$. Then there exists a derivation by the rules of fine-grained step resolution except the clause conversion rule from $LT(S)$ of a final clause $C \Rightarrow \bigcirc false$ such that $\forall x (A(x) \Rightarrow (\exists C \{c' \rightarrow x\}))$.

Proof (Sketch). The proof is analogous to the proof of Lemma 4. As we already noticed, $\exists x (B(x) \land U \land \neg\Phi(x))$ and this can be checked by a first-order resolution procedure. Since $c'$ does not occur in the problem, we can skolemise this existential quantifier with $c'$. We lift now all Skolem constants but $c'$.

Then the loop search algorithm from [5] can be reformulated as shown in Fig. 1. (This algorithm is essentially based on the BFS algorithm for propositional temporal resolution [7].)

Lemma 8 The BFS algorithm terminates provided that all calls of saturation by step resolution terminate. If BFS returns non-false value, its output is a loop formula in $L(x)$.

Note 3 Termination of calls by step resolution can be achieved for the cases when there exists a (first-order) resolution decision procedure [8] for formulae in the universal part, see also [4].

Theorem 9 Temporal resolution is complete if we restrict ourselves to loops found by the BFS algorithm.

5.3. Example

Let us consider a monodic temporal problem $P$ given by $I = 0, U = \{\forall x (B(x) \Rightarrow A(x) \land \neg L(x)), I \Rightarrow \exists x A(x)\}, S = \{s1 : A(x) \Rightarrow \bigcirc B(x)\}, E = \{e1 : \bigcirc L(x), e2 : \bigcirc l\}$. We especially chose such a trivial example to be able to demonstrate thoroughly the steps of our proof search algorithm.
We clausify $\mathcal{U}$ resulting in $\mathcal{U'} = \{u1: (\neg B(x) \vee A(x)), u2: (\neg B(x) \vee \neg L(x)), u3: \neg l \vee A(c)\}$.

- **Step resolution**
  We can deduce the following clauses by fine-grained step resolution:

  $s2 : A(x) \Rightarrow \neg A(x)$  \quad (s1, u1)
  $s3 : A(x) \Rightarrow \neg L(x)$  \quad (s1, u2)

  The set of clauses is saturated. Now we try finding a loop in $\mathcal{U}L(x)$.

- **Loop search**
  The set $S = \{u1, u2, u3, s1, s2, s3\}$; $H_0(x) = true; N_0 = 0; i = 0$.\ LT(S) = \{l1 : A(c') \Rightarrow \neg B(c')\}$

  We deduce the following clauses by fine-grained step resolution (except clause conversion) from $S' = LT(S) \cup \{l1 : true \Rightarrow \neg L(c')\}$:

  $l2 : A(c') \Rightarrow \neg A(c')$  \quad (l1, u1)
  $l3 : A(c') \Rightarrow \neg L(c')$  \quad (l1, u2)
  $l4 : true \Rightarrow \neg B(c')$  \quad (u2, l1)
  $l5 : A(c') \Rightarrow \neg false$  \quad (l3, l1)

  The set of clauses is saturated. Then $N_1 = \{A(c') \Rightarrow \neg false\}$. $H_1(x) = A(x)$. Obviously, $\forall x (H_0(x) \Rightarrow H_1(x))$ is not true.

  Now the set $S_2 = LT(S) \cup \{l6 : true \Rightarrow \neg (A(c') \vee L(c'))\}$ and we deduce from it the following:

  $l7 : A(c') \Rightarrow \neg A(c')$  \quad (l1, u1)
  $l8 : A(c') \Rightarrow \neg L(c')$  \quad (l1, u2)
  $l9 : true \Rightarrow \neg (B(c') \vee L(c'))$  \quad (u1, l6)
  $l10 : true \Rightarrow \neg (B(c') \vee \neg A(c'))$  \quad (u2, l6)
  $l11 : A(c') \Rightarrow \neg L(c')$  \quad (l7, l6)
  $l12 : A(c') \Rightarrow \neg A(c')$  \quad (l8, l6)
  $l13 : true \Rightarrow \neg B(c')$  \quad (u2, l9)
  $l14 : A(c') \Rightarrow \neg B(c')$  \quad (l8, l9)
  $l15 : A(c') \Rightarrow \neg false$  \quad (l8, l11)

  The set of clauses is saturated. $N_2 = \{A(c') \Rightarrow \neg false\}$. $H_2(x) = A(x)$.

  As $\forall x (H_1(x) \Rightarrow H_2(x))$, the loop is $A(x)$.

- **Eventuality resolution**
  We can apply now the eventuality resolution rule whose conclusion is

  $u4 : \neg A(x)$.

- **Step resolution**
  $u5 : \neg l$  \quad (u3, u4)

- **Loop search**
  $S = \{u1, u2, u3, u4, u5, s1, s2, s3\}$; $H_0(x) = true; N_0 = 0; i = 0$. \ LT(S) = \{l1 : A(c') \Rightarrow \neg B(c')\}$; $S' = LT(S) \cup \{l16 : true \Rightarrow \neg l\}$; and we can deduce:

  $l17 : true \Rightarrow \neg false$  \quad (l16, u5)

  that is, a contradiction. The loop is $true$.

- **Eventuality resolution**
  We can apply now the eventuality resolution rule whose conclusion is $\neg true$. The problem is unsatisfiable.

**Note 4** As the example shows, the presence of clauses of the form (6), introduced by the preprocessing, and (8), introduced by the transformation for loop search, might lead to repeated derivations (with free variables and with constants). This can be avoided, however, if instead of generating these clauses, we relax the conditions on substitutions in the definition of rules of fine-grained resolution by allowing original constants and the loop constant to be substituted to variables occurring to the left-hand side of a step clause. It can be seen that the set of derived final clauses would be the same.

Taking into consideration this note, we do not use the reduction for loop search, and clauses $l2$, $l3$, $l7$, $l8$ would not be derived. Instead, at the first iteration of BFS on $L(x)$, we would deduce the following clauses from $S_1 = S \cup \{l1 : true \Rightarrow \neg L(c')\}$:

  $l1' : true \Rightarrow \neg B(c')$  \quad (u2, l1)
  $l3' : A(c') \Rightarrow \neg false$  \quad (s3, l11);

  and at the second iteration from $S_2 = LT(S) \cup \{l6 : true \Rightarrow \neg (A(c') \vee L(c'))\}$:

  $l9' : true \Rightarrow \neg (B(c') \vee L(c'))$  \quad (u1, l6)
  $l10' : true \Rightarrow \neg (B(c') \vee \neg A(c'))$  \quad (u2, l6)
  $l11' : A(c') \Rightarrow \neg L(c')$  \quad (s2, l6)
  $l12' : A(c') \Rightarrow \neg A(c')$  \quad (s3, l6)
  $l13' : true \Rightarrow \neg B(c')$  \quad (u2, l9')
  $l14' : A(c') \Rightarrow \neg B(c')$  \quad (s3, l9')
  $l15' : A(c') \Rightarrow \neg false$  \quad (s3, l11');

**6. Conclusion**

We have described a fine-grained resolution calculus for monodic first order temporal logics over expanding domains. Soundness of the fine-grained inference steps is easy to prove and completeness is shown relative to the completeness proof for the expanding domain for the non-fine grained version [6]. While implementation based on the general calculus would involve generating all subsets of the step clauses with which to apply the step and eventuality
resolution rules, the fine-grained resolution inference rules can be implemented directly using any appropriate first-order theorem prover for classical logics. This makes the new calculus presented here particularly amenable to efficient implementation.

As part of our future work, we will examine extension of this approach to the case of temporal models with constant domains. We also aim to implement and test the calculus defined here.

Finally, we wish to acknowledge support for this work from EPSRC via research grant GR/R45376/01.
