19 **ABSTRACT**

20

21 Tools for social research are critical for developing an understanding of conservation problems and
22 assessing the feasibility of conservation actions. Social surveys are an essential tool frequently applied
23 in conservation to assess both people’s behaviour and to understand its drivers. However, little
24 attention has been given to the weaknesses and strengths of different survey tools. When topics of
25 conservation concern are illegal or otherwise sensitive, data collected using direct questions are likely
26 to be affected by non-response and social desirability biases, reducing their validity. These sources of
27 bias associated with using direct questions on sensitive topics have long been recognised in the social
28 sciences but have been poorly considered in conservation and natural resource management.

29

30 We reviewed specialized questioning techniques developed in a number of disciplines specifically for
31 investigating sensitive topics. These methods ensure respondent anonymity, increase willingness to
32 answer, and critically, make it impossible to directly link incriminating data to an individual. We
33 describe each method and report their main characteristics, such as data requirements, possible data
34 outputs, availability of evidence that they can be adapted for use in illiterate communities, and
35 summarize their main advantages and disadvantages. Recommendations for their application in
36 conservation are given. We suggest that the conservation toolbox should be expanded by
37 incorporating specialized questioning techniques, developed specifically to increase response
38 accuracy. By considering the limitations of each survey technique, we will ultimately contribute to
39 more effective evaluations of conservation interventions and more robust policy decisions.

40

41 **Keywords:** bias; decision-making; illegal; measurement error; survey methods; uncertainty

1. INTRODUCTION

Effective conservation and natural resource management require the identification of the underlying causes of multiple threats to biodiversity such as overexploitation, habitat fragmentation and climate change (Lande, 1998; Thomas et al., 2004). Processes of human decision-making play a key role in understanding how humans use natural resources (Agrawal and Gibson, 1999), protect certain species while persecuting others (Treves and Karanth, 2003), support policy (Treves, 2009), and allocate research investments (Martín-López et al., 2009). Understanding the drivers and impacts of human behaviour is thus at the core of several disciplines and increasingly more attention has been given to their study in conservation.

Many human activities undermining the success of conservation and natural resource management strategies are illegal or otherwise sensitive (e.g. they are taboo; Jones et al., 2008; Keane et al., 2008). Examples of the consequences of illegal natural resource exploitation include extensive deforestation in Indonesia (Jepson et al., 2001); reproductive collapse in the saiga antelope (*Saiga tatarica*) (Milner-Gulland et al., 2003); and “fish wars” between and among user groups and managers in Southeast Asia fisheries (Pomeroy et al., 2007). Whilst indirect approaches for measuring the extent of illegal resource extraction exist (e.g. remote sensing of deforestation rates (Linkie et al., 2004); and analysing ivory seizures data (Underwood et al., 2013)), such techniques tell us little about the characteristics of rules breakers or what drives their behaviour. Yet effective conservation and informed policy decisions require an understanding of the drivers and impacts of human behaviour (St. John et al., 2013). Illegal or sensitive behaviour is thus a frequent source of uncertainty affecting management decisions and compromising evaluations of conservation interventions.

1.1 Assessing human behaviour

Among the methods used to assess human behaviour, for example indirect observation as applied in market surveys, self-reporting through diaries, or the consultation of law-enforcement records (Gavin et al., 2010; Knapp et al., 2010), questionnaires, delivered through face-to-face interviews or self-completed, are the most commonly applied. Questionnaires frequently assess behaviour through direct questions (e.g. “*Have you done X*” *Yes / No*). However, when the topic under investigation is illegal or otherwise sensitive, both non-response and social desirability biases can reduce the validity of data. For example, a non-random proportion of respondents may refuse to participate partly or wholly in the survey creating non-response bias (Groves, 2006); or respondents may provide dishonest answers in order to conform with prevailing social norms, introducing social desirability bias (Fisher, 1993). This tendency of respondents to answer questions in a manner that will be viewed favourably by others may result in under-reporting of undesirable behaviour, such as rule breaking, or over-reporting of desirable behaviour, such as rule compliance (Fisher, 1993).

These sources of bias associated with using direct questions on sensitive topics have long been recognised in the social sciences (e.g. Barton, 1958; Warner, 1965). A number of approaches have been applied in an attempt to identify and correct for these biases, such as relating self-reported behaviours to social-desirability scales (Lee and Sargeant, 2011); measuring comfort with answering sensitive questions (Zink et al., 2006); and analysing mood ratings before and after sensitive questions (Jackson et al., 2012). In addition, question wording or presentation has been manipulated in an attempt to increase reporting of sensitive information. For example, Näher and Krumpal (2011) used forgiving wording, whilst Acquisti et al. (2012) included dummy information on how others responded. Further, by convincing respondents that researchers can discern truthful answers despite what they say, for example, through biological validation, the bogus pipe line procedure seeks to encourage truthful reporting (Adams et al., 2008). The order of questions has also been considered; whilst it is generally recommended that sensitive questions are asked towards the end of questionnaires (Brace, 2008), Acquisti et al. (2012) provide some evidence that respondents are more likely to divulge sensitive information when questions are presented in decreasing order of intrusiveness.

96 Different modes of survey administration have also been adopted based upon the premise that
97 increased privacy increases data validity. For example, anonymous self-complete answer sheets were
98 posted into a ballot box to reduce bias in sexual behaviour surveys in Zimbabwe (Langhaug et al.,
99 2011); Makkai and Mcallister (1992) assessed drug use by using a “sealed booklet”, in which both
100 questions and answers were coded; and Lindstrom et al. (2012) developed a “nonverbal response
101 card” to assess sexual coercion amongst youth in Ethiopia. In addition, advances in technology have
102 led to increased use of computers to deliver surveys, which are not necessarily restricted by literacy as
103 Audio Computer-Assisted Self-Administered Interview (ACASI) systems exist. Highly portable tools
104 such as personal digital assistants (PDAs) have also made an important contribution to investigating
105 sensitive topics. For example, Langhaug et al. (2010) provide evidence that PDAs reduced reporting
106 bias by respondents in developing countries when compared to asking questions about sexual
107 behaviour face-to-face. Other modes of administration that may encourage more honest reporting by
108 increasing respondents’ perceived level of protection include video-enhanced self-administrated
109 computer interviews, computer-assisted telephone interviews, internet-based surveys and interactive
110 voice response (Tourangeau and Yan, 2007).

111
112 Interview setting and the presence of an interviewer or of other people whilst a questionnaire is being
113 administered are also important factors that may affect people’s responses, particularly when the topic
114 is sensitive (Tourangeau and Yan, 2007). The behaviour and characteristics of the person delivering a
115 questionnaire to a respondent can contribute to misreporting, for example survey responses may be
116 influenced by the way in which a question is read out (interviewer behaviour), or the gender of the
117 interviewer (interviewer characteristic). Catania et al. (1996) found that matching respondents and
118 interviewers on gender or allowing respondents to select their interviewer’s gender reduced the
119 discrepancies in self-reported sexual behaviour, but that men and women were not equally affected by
120 these interview conditions and also that these effects varied between topics. Interviewer gender effects
121 have been suggested to occur even for recorded voices using ACASI (Dykema et al., 2012). Because
122 the presence of a third party also affects reporting on sensitive topics, ideally, no one but the
123 interviewer and respondent should be present during the administration of the questions (Tourangeau
124 and Yan, 2007), particularly if that third person is not familiar with the information the respondent has
125 been asked to provide and if the respondent fears any repercussions from revealing it to the bystander
126 (Aquilino et al., 2000).

127
128 Whilst these approaches may, to varying degrees, encourage reporting of sensitive information,
129 evidence suggests that data validity may be increased by applying methods specifically developed for
130 investigating sensitive topics. Such methods, which we refer to as ‘specialized questioning
131 techniques’ (also known as ‘indirect questioning techniques’), developed in disciplines including
132 political and health sciences, ensure respondent anonymity, increase willingness to answer honestly,
133 and critically, make it impossible to directly link incriminating data to an individual (Warner, 1965;
134 Chaudhuri and Christofides, 2013). Despite some recent applications (Solomon et al. 2007; Blank et
135 al. 2009; Razafimanahaka et al. 2012; St. John et al., 2012; Nuno et al. 2013b), most of these
136 techniques have not been applied within a conservation and natural resource management context
137 suggesting unaddressed potential to ask about illegal or otherwise sensitive topics using novel survey
138 techniques. In this study we review methods specifically developed for investigating sensitive topics,
139 providing examples and recommendations for their potential application in conservation.

141 2. METHODS

142
143 To identify methods specifically developed for investigating sensitive topics we searched both ISI
144 (Web of Knowledge) and Google Scholar with the following keywords: “sensitive question*”,
145 “indirect question*”, “sensitive topic*” and “social desirability bias”. We read abstracts for all
146 publications and selected those that mentioned theoretical or empirical applications of methods
147 developed to ask survey participants about sensitive topics. We also considered relevant studies cited
148 by articles found via keyword searches. We did not aim to compile an exhaustive list of papers using
149 each of the specialized questioning techniques found, but rather to identify: a) the different types of

150 specialized questioning techniques described in peer-reviewed literature and; b) the different versions
 151 of each of the techniques found.

152

153 We described each method and recorded their main characteristics, such as data requirements (e.g.
 154 need for data on a non-sensitive characteristic), possible data outputs (e.g. estimate of behaviour
 155 prevalence, link to explanatory variables associated with behaviour), availability of evidence that they
 156 can be adapted for use in illiterate communities, and summarized their advantages and disadvantages.
 157 When available, we recorded information when researchers compared different techniques (e.g. in
 158 terms of accuracy, efficiency, perceptions, etc.). When a certain technique had not been used in
 159 illiterate communities and/or a developing country context, we considered that the following
 160 requirements would have to be met for its potential use under such conditions: place minimal
 161 cognitive demands on respondents; being highly portable; and inexpensive. Several methods reported
 162 in different studies were adaptations or variants of a previously described method so we grouped them
 163 accordingly.

164

165 **3. RESULTS**

166

167 We identified seven types of method developed specifically for investigating sensitive topics,
 168 particularly for estimating the proportion of respondents involved in sensitive activities: randomised
 169 response techniques; nominative technique; unmatched-count technique; grouped answer method;
 170 crosswise, triangular, diagonal and hidden sensitivity models; surveys with negative questions; and
 171 the bean method (Table 1).

172

173 **Table 1.** Summary of methods reported in this study and a non-exhaustive list of studies in which
 174 these techniques were used

Technique	Previously used in conservation or natural resource management?	Methods comparison studies completed	Evidence that method can be adapted for use in illiterate community?	Possible data outputs
Randomised response technique (RRT; Warner et al. 1965)	Yes (Solomon et al., 2007; Blank et al. 2009; St. John et al., 2010, 2012)	RRT with direct questions (Solomon et al. 2007); RRT with UCT (Coutts and Jann, 2011); RRT with nominative (St. John et al., 2010)	Yes	Proportion of sample population engaging in sensitive behaviour + link to explanatory variables associated with behaviour
Nominative technique (Miller, 1985)	Yes (St. John et al., 2010)	Nominative with RRT and direct questions (St. John et al., 2010)	Yes	Proportion of sample population engaging in sensitive behaviour
Unmatched-count technique (UCT; Droitcour et al., 1991)	Yes (Nuno et al., 2013b)	UCT with direct questions (Tsuchiya et al., 2007); UCT with RRT (Coutts and Jann, 2011)	Yes	Proportion of sample population engaging in sensitive behaviour + link to explanatory variables associated with behaviour
Grouped answer method (Droitcour and Larson, 2002)	No	None	Yes	Proportion of sample population engaging in sensitive behaviour

Crosswise model (CM; Yu et al. 2008), Triangular model (TM; Yu et al. 2008), Diagonal model (DM; Groenitz 2014)	No	CM with direct questions (Jann et al. 2012)	Maybe	Proportion of sample population engaging in sensitive behaviour + link to explanatory variables associated with behaviour
Hidden sensitivity model (HSM; Tian et al., 2007) Surveys with negative questions (Esponda and Guerrero, 2009)	No	None	Maybe	Proportion of sample population engaging in sensitive behaviour
Bean method (BM; Lau et al. 2011)	No	BM with direct questions (Lau et al. 2011)	Yes	Proportion of sample population engaging in sensitive behaviour

175

176

177 3.1 Randomized response techniques

178 First described by Warner (1965), the randomised response technique (RRT) uses a randomising
179 device (e.g. dice or a spinner) to introduce an element of chance into the question-answer process.
180 RRT has been subject to considerable methodological development aimed at increasing statistical
181 efficiency whilst maintaining respondent protection (Lensvelt-Mulders et al., 2005). Various RRT
182 designs have been applied across a range of sensitive topics including illegal abortion (Silva and
183 Vieira, 2009); social security fraud (Böckenholt and van der Heijden, 2007); and illegal drugs use
184 (Simon et al., 2006). RRT has also been applied to rule-breaking in conservation (Blank et al. 2009;
185 St. John et al., 2010, 2012) where there is evidence that it can be adapted for completion by people
186 with low literacy levels (Solomon et al. 2007; Razafimanahaka et al., 2012). Due to the randomization
187 of questions, there is an added source of variability and RRT requires larger sample sizes than direct
188 questions; the forced-response randomised response technique is one of the more statistically efficient
189 designs (Lensvelt-Mulders et al., 2005). Forced-response RRT instructs (rather than forces)
190 respondents to either: respond to a sensitive question truthfully (answering ‘yes’ or ‘no’); or to give a
191 prescribed ‘yes’ or ‘no’ answer. For example, rolling a pair of dice, respondents may be instructed to:
192 answer a sensitive question truthfully when the dice sum five through to ten (probability = 0.75); give
193 a fixed answer ‘yes’ when the dice sum two, three or four (probability = 0.167); and a fixed answer
194 ‘no’ when the dice sum 11 or 12 (probability = 0.083) (Figure 1). Respondents never reveal the result
195 of the dice roll so it is impossible to distinguish truthful from prescribed responses. Following Hox
196 and Lensvelt-Mulders (2004), prevalence of sensitive behaviours are calculated by:

$$197 \pi = \frac{\lambda - \theta}{s} \quad \text{eqn 1}$$

198 where π is the estimated proportion of the sample who have undertaken the behaviour, λ is the
199 proportion of all responses in the sample that are ‘yes’, θ is the probability of the answer being a
200 ‘forced yes’, s is the probability of having to answer the sensitive question truthfully.

201

202 By adapting the standard logistic regression model (van den Hout et al., 2007), it is possible to
203 explore how covariates relate to people’s involvement in sensitive behaviours. For example, St. John
204 et al. (2012) investigated how innocuous indicators of behaviour, such as farmers’ attitudes towards
205 carnivores, relate to illegal carnivore killing reported via RRT. Further, the development of a sum
206 score proportional odds model for RRT data offers an opportunity to reveal associations that remain
207 undetected when data are analysed in a univariate way (Cruyff et al., 2008). Such studies pave the
208 way for using RRT to identify drivers of illicit behaviour.

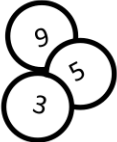

209

210 Typically, RRT estimates the proportion of a population engaged in stigmatizing or illegal behaviours.
211 However, in addition to knowing the proportion of the population involved in such behaviours, we
212 often want to understand the quantitative nature of the behaviour. For example, we may want to
213 simultaneously know the proportion of a population illegally killing a species, and the quantity that
214 they kill. Crude estimates of quantity can be made by using a randomising device (e.g. a spinner with
215 blank and numbered segments) and instructing respondents to: respond truthfully by ticking one of

216 several discrete categorical response options when the spinner lands on a blank segment (e.g. '1 =
 217 killed zero leopards', '2 = killed between one and five leopards', 3 = etc.); or 'forcing' them to tick
 218 the corresponding category when the spinner lands on a numbered segment (Peeters et al., 2010) (see
 219 also Conteh et al., this issue). However, more refined estimates become possible when respondents
 220 'scramble' their answers. For example, by adding a number from a known distribution to their
 221 numeric response ('additive' RRT) (Pollock and Bek, 1976) (Figure 2); or by multiplying their
 222 numeric response by a number chosen at random from a known distribution and reporting the product
 223 ('multiplicative' RRT) (Eichhorn and Hayre, 1983). A major advantage of both additive and
 224 multiplicative RRT is that they allow sensitive data to be gathered from every respondent. However,
 225 RRT designs such as these place considerable demand upon respondents and may therefore not be
 226 viable where literacy and numeracy are low. The application of these types of RRT in a conservation
 227 context is in its infancy as such their utility still remains to be explored.
 228

	INSTRUCTIONS
	Please shake the two dice – do not let me see what they land on
	Remember the rules, add together the numbers on the two dice: 2, 3, 4 = say 'Yes' 5 – 10 answer the question below truthfully 'Yes' or 'No' 11, 12 = say 'No'
	QUESTION In the last 12 months did you kill any leopards?

229
 230 **Figure 1.** An example instruction card for the forced response randomized response technique.
 231 Respondents are provided with an opaque beaker, two dice and a set of question cards each displaying
 232 the instructions. The dice are rolled and the instructions followed. Depending upon how the survey is
 233 administered, respondents provide their answers either by saying 'yes' or 'no' out load to an
 234 interviewer, or by personally recording their answer. The respondent never reveals the result of the
 235 dice role. Killing a leopard is used here (and in Figures 2 and 3) as an example of an activity of
 236 conservation concern that may be illegal in some study systems.

	INSTRUCTIONS
	Please take one numbered ball out of the sack – do not show it to me
	Remember the rules: Add the number on the ball to your truthful answer
QUESTION	In the last 12 months how many leopards did you kill?

238
 239 **Figure 2.** An example instruction card for the additive randomized response technique. Respondents
 240 are provided with a cloth sack containing numbered balls with a known distribution. Respondents
 241 select one ball from the sack and add the number shown on the ball to their numeric response to the
 242 question. The respondent never reveals the number displayed on the ball they select. Respondent may
 243 call their answers out load to an interviewer or record them personally.

244
 245 *3.2 Nominative technique*

246 The nominative technique (NT) is a variant of multiplicity sampling (sometimes called network
 247 sampling) (Sirken, 1972; Sudman et al., 1988) and was developed expressly to investigate heroin use
 248 (Miller, 1985). The NT requires respondents to report on the deviant behaviour of close friends. With
 249 correction for duplication, to account for multiple respondents reporting the same person, the number
 250 of people doing the deviant behaviour can be estimated (Miller, 1985). On three occasions the NT was
 251 used to investigate heroin use in the American National Survey on Drug Abuse. On each occasion the

252 NT estimated higher lifetime prevalence use of heroin compared to anonymous self-complete
 253 questionnaire data. Despite this apparent advantage, the NT does not appear to have been applied
 254 beyond the Miller (1985) studies before St. John et al. (2010) applied it to rule-breaking in
 255 conservation; although this may be due to researchers' reluctance to publish unfavourable findings.
 256 The NT is easy to use: respondents are asked to report the number of close friends that they know for
 257 certain have done a certain behaviour (e.g. broken a hunting rule); and how many other people they
 258 believe know about the nominated friend's behaviour (Figure 3). Based on this information,
 259 prevalence rates can be calculated by:

$$260 \quad T_x = \sum_{j=1}^n \frac{A_j}{1+B_j} \quad \text{eqn 2}$$

261 where T_x is the number of people breaking a rule in a sample of size n , A_j is the number of rule
 262 breakers known to individual j and B_j is the number of friends (other than j) that know of the
 263 nominated friend's rule-breaking (Miller, 1985; St. John et al., 2010). Before using the NT, familiarity
 264 of respondents with their friend's behaviour in respect of the topic under investigation must be
 265 considered. Where respondents' knowledge of their friend's behaviour is weak, NT reveals little about
 266 the prevalence of sensitive behaviours (St. John et al., 2010).
 267

1. Most of us know many people. But usually only a few, if any, of these are close friends. **About how many of your close friends go hunting?**

If answer to is 0, end interview here.

2. This question is about those close friends. Keep their names to yourself. We want to know about them, but we do not want to know who they are. **How many of your close friends who go hunting can you say for certain have broken hunting rules in the last year?**

If answer is 0, end interview here. If only 1 friend is reported go to next question directly. If more than 1 friend reported apply randomised selection.*

3. Please answer the following question with respect to your close friend that you are thinking of. **As far as you know in the last 12 months did your friend kill any leopards?**

4. Now we would like you to think about this friend's other close friends, besides yourself. **As far as you know, how many of this person's close friends, besides yourself, know for sure that this person has broken hunting rules in the last year?**

268 **Figure 3.** Example questions for the nominative technique. This method could be administered
 269 through a face-to-face interview or self-administered using pen-and-paper, or computer. *Randomised
 270 selection requires respondents to write down the initials of each friend and number them from 1 to the
 271 end of the list; predefined instructions (e.g. if the number of close friends reported in question 1 is 5,
 272 ask about friend number 2 on the list) in order to identify which friend they should think about when
 273 answering the sensitive question(s).
 274

275
 276 *3.3 Unmatched-count technique*

277 The unmatched-count technique (UCT), also known as the list experiment or item count technique,
 278 has been used in the last three decades to ask about sensitive topics such as sexual risk behaviours
 279 (Hubbard et al., 1989), dangerous driving (Sheppard and Earleywine, 2013), racial prejudice (Blair
 280 and Imai, 2012) and illegal bushmeat hunting (Nuno et al., 2013b). Survey respondents are randomly
 281 allocated into baseline and treatment groups. Baseline group members receive a list of non-sensitive
 282 items while the treatment group members are shown this same list with an additional sensitive item
 283 added to it (Figure 4). All respondents are asked to indicate how many, but not which, items apply to
 284 them. Differences in the means between baseline and treatment groups are used to estimate the
 285 prevalence of the sensitive behaviour (Droitcour et al., 1991).

286
287 If the respondents are engaged in all or none of the listed activities, answer secrecy is removed and
288 they may deflate (to avoid association with a socially undesirable item) or inflate (to avoid
289 dissociation with a socially desirable item) their true answers, causing ceiling and floor effects
290 (Zigerell, 2011). To minimize these issues, non-sensitive items should include at least one item whose
291 prevalence is extremely low and one item with very high prevalence (Tsuchiya et al., 2007). Also,
292 non-sensitive items completely different from the target item may cause suspicion (Hubbard et al.,
293 1989); a common theme should be used (e.g. include the sensitive item “poaching” together with non-
294 sensitive livelihood strategies, such as herding and farming). Tsuchiya et al. (2007) suggested that
295 lists should include two or three non-sensitive items in order to ensure answer secrecy while allowing
296 easy mental counting. To analyse UCT data, UCT answers can be analysed in function of the
297 explanatory variables, card type (i.e. treatment or baseline) and interactions of the card type variable
298 with each predictor; the interactions between predictor variables and treatment status indicate
299 differences between the reported number of behaviours in the two conditions for each predictor
300 (Holbrook and Krosnick, 2010).

301
302 There is some evidence that the UCT is more effective than direct questions for estimating prevalence
303 of sensitive behaviours (Tsuchiya et al., 2007; Sheppard and Earleywine, 2013) and produces similar
304 or higher estimates than RRT (Coutts and Jann, 2011). In addition, UCT has been reported as less
305 troublesome and easier to understand than RRT (Hubbard et al., 1989). Its simplicity and ease of use
306 in areas of high illiteracy are two main advantages (Nuno et al., 2013). However, UCT has been
307 shown to have limited use for very rare behaviours given the wide standard errors around estimates
308 (Tsuchiya et al., 2007). Further, UCT requires large sample sizes; more than 1000 respondents
309 completed UCT questions administered to determine household participation in bushmeat hunting in
310 western Serengeti returning an estimate with a $\pm 5\%$ standard error (Nuno et al., 2013b), suggesting
311 potential trade-offs between accuracy and precision.

312
313 Ongoing UCT developments have focused on increasing its statistical efficiency by improving the
314 estimation process (Corstange, 2009; Blair and Imai, 2012) and the survey administration design
315 (Droitcour et al., 1991; Petróczi et al., 2011; Glynn, 2013). For example, Imai (2011) proposed
316 nonlinear least squares and maximum likelihood estimators for a multivariate analysis. Instead of
317 using a standard design, a double UCT presents the sensitive item to all respondents by using two
318 baseline lists; both experiments provide estimators of the sensitive behaviour that can be averaged
319 (Droitcour et al., 1991). Recently described by Petróczi et al. (2011), a simplified and more efficient
320 version of the UCT, the single sample count (SSC), also asks respondents how many items apply to
321 them without revealing which ones but embeds the sensitive question among four unrelated innocuous
322 questions with known population distributions (e.g. phone numbers ending in odd numbers or
323 birthdays in the first half of the year). This avoids the need to allocate respondents to control groups,
324 since all participants see the same questions. The prevalence estimate from SSC data is then
325 calculated as:

$$326 \pi = (\lambda/n) - b \quad \text{eqn 3}$$

327 where π is the estimated population distribution of the 'yes' answers to the sensitive question, λ is the
328 observed number of 'yes' answers, n is the sample size, and b is the expected value of responses for
329 the baseline non-sensitive questions. Another recent adaptation of UCT, the item sum technique (IST;
330 Trappmann et al., 2014), quantifies sensitive behaviours (e.g. how much time people spend poaching
331 instead of only how many people poach). The IST is administrated similarly to the UCT but it
332 incorporates sensitive and innocuous items that can be measured on a quantitative scale (preferably
333 the same scale, such as hours or monetary units). Respondents are asked to report the sum of the
334 answers to all the activities they engage in (e.g. how many hours they spend per month herding,
335 farming and hunting). However, because respondents in the baseline group only report the sum from
336 non-sensitive activities, the extent of the sensitive behaviour can be calculated from the mean
337 difference of answers between the two subsamples (Trappmann et al., 2014).

338

339
 340 **Figure 4.** An example of baseline and treatment unmatched-count technique (UCT) lists viewed by
 341 survey respondents randomly allocated to either baseline or treatment groups. Respondents are
 342 required to report the total number of items that apply to them without identifying any individual item.
 343 “Hunting” is used here (and all figures thereafter) as an example of an activity of conservation
 344 concern that may be conducted illegally in some study systems and/or under certain conditions.

345
 346 *3.4 Grouped answer method*

347 The grouped answer method, also known as the 2- or 3-card method, was developed in the late 1990s
 348 to estimate irregular migration, including illegal or undocumented status (GAO, 1999; Droitcour and
 349 Larson, 2002). A list of mutually exclusive items including the sensitive item (e.g. the person’s main
 350 occupation) is divided into three groups. The respondents are randomly allocated to one of two
 351 treatments (e.g. Card 1 or Card 2, Figure 5), which differ only in the grouping of non-sensitive items
 352 with the sensitive item (e.g. hunting); i.e. in Figure 5, the sensitive item remains in Box B for both
 353 cards but non-sensitive activities swap between Box A and B. The respondents are then asked to
 354 indicate which group they belong to (e.g. A, B or C of Card 1, Figure 2), but not which actual item
 355 within the group applies to them. The prevalence of the sensitive item is then estimated by comparing
 356 the proportion of people from each of the two treatments who picked the answer group containing the
 357 sensitive item, while variance of the sensitive behaviour is estimated by adding the variances from the
 358 groups incorporated in the calculations (Droitcour and Larson, 2002). For example, a simple estimate
 359 of the sensitive behaviour can be obtained by subtracting the proportion of people that choose Box A
 360 in Card 1 from those who choose Box B when shown Card 2 (Figure 5). If the mutually exclusive
 361 items are also exhaustive, then the prevalence of the sensitive behaviour can be estimated by
 362 subtracting the Box C (averaged from Card 1 and 2) and Box A (summed from Card 1 and 2)
 363 percentages from a total of 100%.

364
 365 GAO (2007) recommended using follow-up questions for respondents who did not pick a group with
 366 the sensitive item. These follow-up questions would aim to identify the specific category that applied
 367 to the respondents by obtaining direct information on all non-sensitive items for validity checking
 368 through comparison with other data sources. If respondents are asked other sociodemographic
 369 characteristics during follow-up, then correlates for each non-sensitive category may be obtained
 370 directly.

371
 372 Respondent acceptability and understanding of this technique were considered by GAO (2006) and
 373 Larson and Droitcour (2012) who described this technique as promising, although still requiring
 374 further testing. To date, this method has only been recommended to produce group-level estimates,
 375 without any attempt to conduct univariate or multivariate analysis. For example, to link predictor
 376 variables with engagement in the sensitive activity, one could split the analyses according to main
 377 variables of interest. Additionally, to our knowledge, estimates from this method have never been
 378 compared with direct questioning. Main limitations of this technique are thus its current lack of
 379 evidence that it can be subjected to efficient multivariate analysis, large sample size requirements, and
 380 the current lack of comparison and validation studies. Nevertheless, its simplicity in administration
 381 and ease of use mean that further investigation into this technique may be worthwhile.

382

CARD 1

C	Other

CARD 2	
A	Trading Remittances
B	Farming Livestock herding Hunting
C	Other

Figure 5. An example of cards used for the grouped answer method. Depending upon the treatment group they are assigned to, respondents are required to report which group on Card 1 or 2 they belong to without identifying which items apply to them.

3.5 Crosswise, triangular, diagonal and hidden sensitivity models

Developed to address concerns that asking respondents to use randomizing devices can create confusion (Chaudhuri and Christofides, 2013), the techniques that follow do not depend on a randomizing device. However, randomization occurs implicitly (Tian and Tang, 2013).

The crosswise (CM) and triangular (TM) models, first described by Yu et al. (2008), expose respondents to two questions, only one of which is sensitive, and respondents then provide a joint answer to both questions. For both techniques, the probability distribution of the non-sensitive question must be known (e.g. month of birth) and it should be unrelated to the sensitive behaviour. However, these techniques differ in their specific response rules. In the CM, respondents are told to choose option A if the answer is the same for both questions (i.e. ‘yes’ to both questions or ‘no’ to both questions) and option B if one answer is ‘yes’ and the other is ‘no’. In the TM, respondents are asked to choose option A if the answer is ‘no’ to both questions and option B if at least one answer is ‘yes’ (Figure 6).

While both the TM and CM ask one sensitive question at a time, the hidden sensitivity model (HSM) has been developed to analyse the association between several sensitive questions by asking them simultaneously (Tian et al., 2007). To ask two sensitive questions simultaneously, e.g. about illegal hunting and corruption, HSM requires a non-sensitive question with four mutually exclusive response categories each with a known probability distribution (e.g. A, B, C and D corresponding to different quarters in a year). Respondents who do not engage in any of the sensitive behaviours, should reply truthfully to the non-sensitive question (A, B, C or D) while the other respondents should choose B if they are only engaged in the second sensitive behaviour, C if only the first and D if both, hiding the sensitive attribute of respondents (Figure 7).

The diagonal model (DM) recently developed by Groenitz (2014) expands upon CM, TM and HSM by allowing researchers to investigate multichotomous sensitive questions, such as levels of income (which is often considered sensitive). Again, respondents are asked a sensitive and a non-sensitive question with known distribution, each with multiple categories (e.g. four in the example below). Respondents give the answer:

$$A = [(W - X) * \text{mod } k] + 1 \quad \text{eqn 4}$$

where W is the number (1 to 4) corresponding to their categorical answer to the non-sensitive question, X is the number (1 to 4) corresponding to their categorical answer to the sensitive question, and k is the number of categories in the non-sensitive question. However, respondents are not provided with this formula but simply with a table from which they can select their answer to the sensitive and non-sensitive questions simultaneously (Figure 8). Using the table, respondents report only the number in the table which provides the required answer A depending on X and W . Because it is not possible to identify the X value from their answer A, answer secrecy is guaranteed. When asking a respondent multiple sensitive questions (e.g. how many leopards did you kill in the last 12

427 months?; how many lions did you kill in the last 12 months?) where responses may fall within the
 428 same category (e.g. category 1 equals none, category 2 equals between 1 and 3 etc.), the non-sensitive
 429 question posed simultaneously must also be changed in order to ensure that respondents do not reveal
 430 truthful responses to either X or W.

431
 432 To our knowledge, only the CM and HSM have been empirically explored (Tian et al., 2007; Jann et
 433 al., 2012; Vakilian et al., 2014). Given this, and the similarity between these four techniques, we will
 434 now focus on the CM. For CM, prevalence estimates are calculated by:

$$435 \pi = \frac{\lambda + p - 1}{2p - 1}, p \neq 0.5 \quad \text{eqn 5}$$

436 where π is the estimated proportion of the sample who have undertaken the sensitive behaviour, λ is
 437 the observed proportion of all responses in the sample that choose option A (i.e., ‘yes’ to both
 438 questions or ‘no’ to both questions), and p is the known population prevalence of the non-sensitive
 439 item (Jann et al., 2012). To analyse the effects of multiple covariates, modified logistic regression
 440 models and modified linear probability models may be used. For example, Jann et al. (2012) used this
 441 technique to investigate plagiarism by students, linking to several predictors, and found that CM
 442 produced higher prevalence rates than direct questioning. Although no comparative analysis is
 443 available, Jann et al. (2012) also suggest that the CM may be better than RRT and UCT due to its
 444 statistical efficiency and lack of an obvious self-protective answering strategy.
 445

Q1: Is your birthday in January, February or March? Q2: Did you hunt without a license last year? <u>How are your answers to these two questions? Pick A or B</u>			
CROSSWISE MODEL		TRIANGULAR MODEL	
A	NO to both questions OR YES to both questions	A	NO to BOTH questions
B	YES to one of the questions AND NO to the other	B	YES to ONE of the questions

446
 447 **Figure 6.** An example of a question card to be used in studies applying either the crosswise model or
 448 the triangular model. Respondents are asked to provide a joint answer to both questions following
 449 different rules according to specific technique.

450

According to the table below please pick the option (A, B, C or D) that corresponds to your answers:

W: When is your birthday?

X: Did you hunt without a license last year?

Y: Did you pay a bribe to a park ranger last year?

	W=Jan-Mar	W=Apr-Jun	W=Jul-Sep	W=Oct-Dec
X=No, Y=No	A	B	C	D
X=No, Y=Yes	Please tick option B			
X=Yes, Y=No	Please tick option C			
X=Yes, Y=Yes	Please tick option D			

451
452 **Figure 7.** An example of a question card to be used in studies applying the hidden sensitivity model.
453 Respondents are asked to answer A, B, C or D according to the card instructions; people that have
454 done any of the sensitive activities are required to answer irrespectively of their actual birthday,
455 protecting their answers.

456

Using the table below please pick the number (1, 2, 3 or 4) that corresponds to your answers to both questions simultaneously:

- When is your birthday? (= W)
- How many times did you go hunting inside the park last year? (= X)

	January February March	April May June	July August September	October November December
0	1	2	3	4
1, 2 or 3	4	1	2	3
4, 5 or 6	3	4	1	2
6, 7, 8....	2	3	4	1

457
458 **Figure 8.** An example of a question card to be used in studies applying the diagonal model. After
459 being read or shown two questions (one sensitive and the other non-sensitive), respondents should
460 report the number (1, 2, 3 or 4) in the table that provides the required answer depending on both
461 questions simultaneously.

462

463 3.6 Surveys with negative questions

464 In conventional closed check-list questions (Newing, 2011) respondents are required to answer
465 questions or statements phrased in a positive direction (e.g. 'I earn...') by selecting the response
466 category that applies to them. However, 'negative questions' ensure respondent privacy by phrasing
467 questions in a negative direction (e.g. 'I do not earn...') and asking respondents to select a response
468 category to which they do not belong (Esponda and Guerrero, 2009). For example, a negative
469 question for assessing annual income may look like this (Esponda and Guerrero, 2009):

470

471 I do not earn:

472 Less than 30 000 dollars a year

473 Between 30 000 and 60 000 dollars a year

474 More than 60 000 dollars a year

475

476

477 The number of respondents e that belong to a certain category j is estimated using: eqn 6
478
$$e_j = n - (c - 1) \times r_j$$

479 where n is the total number of participants, c is the number of categories and r_j is the number of
480 respondents who report category j (Xie et al., 2011).

481
482 This technique requires both that questions be phrased in the negative (e.g. ‘I do not earn...’), and that
483 multiple true options are available for respondents to choose from. For example, if a respondent earns
484 more than 60,000 dollars a year they could choose either option a) or b) as their answer to the
485 question above because both answer the negative question truthfully. However, in order to reduce the
486 chance of bias in respondents’ selection of response categories, a randomizing device with $c-1$ options
487 is used in private by the respondent to obtain a value m , they then choose the m^{th} true alternative from
488 the list accordingly (Esponda and Guerrero, 2009). Rather than using a randomising device with
489 known probabilities drawn from a uniform distribution, Xie et al. (2011) proposed that the probability
490 of selecting response categories should follow a Gaussian distribution centred at the positive category.
491 This approach achieves higher accuracy but reduces respondent privacy. Bao et al. (2013) has also
492 suggested improvements to this method that ensure that estimates of the number of people selecting
493 each category are always positive (negative estimates can unrealistically occur with a standard
494 estimation process with low sample sizes).

495
496 ‘Negative questions’ is a relatively recent survey technique still under development, with the few
497 empirical applications currently limited to communications and technology. For example, Horey et al.
498 (2007) used this approach to implement anonymous data collection on sensor network platforms. Easy
499 to administer, it seems a promising method although its validity and how it compares to other
500 questioning techniques still remain to be investigated.

501
502 *3.7 Bean method*
503 The “bean method” was recently developed to collect information on health risk behaviours (Lau et
504 al., 2011). This method presents respondents with one large and one small jar of beans, both
505 containing mixed-up beans of different colours. The number of beans should be large enough so that
506 addition or removal of a single bean from either jar is not noticeable. Respondents are instructed to
507 move a black bean from the smaller jar to the large jar if the answer to a sensitive question is ‘no’ and
508 to move a bean of another specified colour from the small jar to the large jar if the answer is ‘yes’.
509 Respondents do this in private, without being watched by the interviewer. After multiple respondents
510 have completed the exercise, changes in the bean composition in the jars are used to estimate the
511 prevalence of a sensitive behaviour.

512
513 This method is technologically simple, very easy to administer and Lau et al. (2011) reported that it
514 was well received by respondents. Further, it generally produced similar or higher estimates of the
515 sensitive behaviour compared to face-to-face direct questions (Lau et al. 2011). However, if
516 administered as described here, the bean method only produces group-level estimates.

517 **4. DISCUSSION**

519
520 Increasing emphasis is being placed upon the social dimensions of conservation (Sandbrook et al.,
521 2013) and this may present challenges to scientists trained largely in the natural sciences. However,
522 social science techniques must be applied with the same rigour demanded of methods used to monitor
523 ecological factors (St. John et al., 2013). Tools for social research are essential for understanding the
524 feasibility of conservation actions and identifying the scope of conservation problems (Raymond and
525 Knight, 2013). Social surveys are an essential tool often used in conservation both to assess people’s
526 behaviour and to understand its drivers (White et al., 2005). However, the weaknesses and strengths
527 of different tools must be considered. When topics of conservation concern are illegal or otherwise
528 sensitive, inferences drawn from survey data must be interpreted and used very carefully due to
529 potential influences of non-response and social-desirability bias (St. John et al., 2010). We suggest
530 that the conservation toolbox should be expanded by incorporating specialized questioning techniques

531 that have been developed in a range of disciplines specifically to reduce these biases and improve
532 response accuracy.

533

534 As shown in our study, a variety of specialized questioning techniques have been developed to protect
535 respondent confidentiality and increase response accuracy. Whilst these techniques represent
536 promising and useful developments in the field of quantitative social science, they should not be seen
537 as a panacea. Their limitations should be considered and evaluated against other criteria. The general
538 disadvantages in using these specialized techniques rather than direct questioning include the
539 increased complexity of data analysis, higher sample size requirements and the more limited form that
540 the questions can take. Nevertheless, a number of recent studies have presented improved designs and
541 analysis for these techniques (e.g. Bullock et al., 2011; Petróczi et al., 2011; Blair and Imai, 2012). In
542 some cases, given the larger sample size required for some of the techniques, it is not cost-efficient to
543 use them for non-sensitive topics. Also, regardless of the survey technique, some participants may still
544 give evasive responses; as such estimates are still likely to be conservative. A key consideration is the
545 limited availability of studies comparing different techniques and their estimates' accuracy. Ground-
546 truthing estimates from social surveys is rarely conducted (White et al., 2005) and validation studies
547 in which the reliability of responses is verified (e.g. by surveying convicted criminals and comparing
548 their answers to their criminal records) are particularly difficult when dealing with sensitive topics.
549 The use of complementary methods for triangulation may help overcome the constraints inherent to
550 each individual research tool.

551

552 Although these specialized questioning techniques have been applied in a number of socio-
553 demographic and cultural contexts (e.g. Solomon et al. (2007) in villages in Uganda and St. John et al.
554 (2010) with fishers in the UK), relatively little attention has been given to the trade-offs between
555 technique complexity and intellectual demand, perceived feelings of anonymity and trust. For
556 example, while the UCT was developed to address some of the criticisms of RRT (that it may be
557 constrained by belief in trickery or by respondents' feelings of confusion and education level
558 (Hubbard et al., 1989; Landsheer et al., 1999)), little attention has been given to exploring
559 respondents' perceptions towards these techniques. In a small pilot study conducted to investigate the
560 feasibility of using specialized questioning techniques to assess poaching in the Serengeti, Nuno
561 (2013) found that respondents found the UCT easier to understand than the RRT. Pilot studies testing
562 the feasibility of multiple techniques before conducting the main data collection can thus provide
563 essential information about the adequacy of different survey instruments and the importance of such
564 pilots cannot be overemphasized. Additional studies that robustly consider the appropriate use of each
565 of these techniques in terms of costs, suitability in low literacy populations and efficiency of statistical
566 estimators would provide much needed information that could be used to compare their feasibility,
567 advantages and potential problems in a single framework.

568

569 Novel applications of existing methodologies may also contribute to our understanding of
570 involvement in illicit behaviours. For example, Moro et al. (2013) used choice experiments to elicit a
571 household's intention to hunt illegally in the Serengeti under different conditions by embedding
572 hunting as one option across a range of livelihood strategies. Nielsen et al. (2013) also suggested that
573 the use of hypothetical scenarios in choice experiments is likely to make the elicitation of preferences
574 about illegal activities less sensitive. Choice experiments may then be used to obtain essential
575 information on sensitive behaviours by providing information on preferences and trade-offs in relation
576 to several attributes of the choice to engage in those activities. Other techniques developed in the
577 economic sciences that may be useful to investigate decisions about engagement into sensitive
578 behaviours include, for example, willingness-to-pay studies (e.g. asking willingness to accept
579 compensation for forgoing illegal harvest) and economic experiments using lotteries to investigate
580 relations between income and wildlife harvest (Sirén et al., 2006).

581

582 Advances in technology also present opportunities; for example, smartphones have been used to
583 obtain information about illegal activities which has been collected by local communities in
584 developing countries (Vitos et al., 2013). Additionally, occupancy modelling has been suggested as a
585 potential tool to determine more accurate illegal wildlife trade estimates from market data by taking

586 detectability into account (Barber-Meyer, 2010), and capture-recapture methods have been used to
587 estimate the size of difficult-to-count human populations (e.g. clients of prostitution; Roberts and
588 Brewer, 2006) through overlap between different datasets or subsequent arrest records.

589

590 While our study focused on describing specialized questioning techniques that have been developed to
591 investigate sensitive topics, and mainly focuses on techniques used to reduce non-response and under-
592 reporting due to social desirability biases, there are a number of other factors to be considered. For
593 example, despite being generally unaddressed in conservation, it is likely that people over-report
594 involvement in pro-conservation behaviours, as already observed for other pro-social behaviours such
595 as charitable giving (Lee and Sargeant, 2011). Moreover, acquiescence bias (tendency to agree or
596 disagree with all or most of the questions asked) and extremity bias (tendency to choose extreme
597 ratings in response-scale formats) are frequent problems affecting social surveys. For example,
598 Javeline (1999) showed the magnitude of the acquiescence problem in societies where norms of
599 civility and respect distort attitude reports, and suggested that forced-choice questions (offering two
600 opposing views and instructing respondent to select one of them) are more effective than traditional
601 Likert scales in addressing this problem. Identifying, reducing and/or accounting for these multiple
602 sources and types of bias in social surveys in conservation is thus essential and deserves further
603 attention and research.

604

605 **5. CONCLUSION**

606 Given the promising ongoing developments in survey techniques and the well-known limitations of
607 asking sensitive questions directly, we suggest that specialized questioning techniques developed
608 specifically to investigate sensitive topics should be further explored. When evaluating conservation
609 interventions and making policy decisions, observation uncertainty related to the measurement
610 process and its implications should be made explicit, and should be fully considered (Nuno et al.,
611 2013a). By identifying and acknowledging the limitations of each survey technique, we can
612 incorporate this information into wider conceptual and methodological frameworks aimed at
613 supporting decision-making, such as the management strategy evaluation (Bunnefeld et al., 2011).
614 Only by guaranteeing that decisions are evaluated in a comprehensive, robust and transparent manner
615 can we plan for effective conservation.

616

617 **ACKNOWLEDGEMENTS**

618 AN was supported by the Portuguese Foundation for Science and Technology (FCT; doctoral grant
619 SFRH/BD/43186/2008). The funding source had no involvement in the conduct of the research and
620 preparation of the article. Thank you to Dr David Roberts of DICE, School of Anthropology and
621 Conservation for comments on an earlier draft of this manuscript. Two anonymous reviewers gave
622 valuable comments on the manuscript.

Table 1. Summary of methods reported in this study and a non-exhaustive list of studies in which these techniques were used

Technique	Previously used in conservation or natural resource management?	Methods comparison studies completed	Evidence that method can be adapted for use in illiterate community?	Possible data outputs
Randomised response technique (RRT; Warner et al. 1965)	Yes (Solomon et al., 2007; Blank et al. 2009; St. John et al., 2010, 2012)	RRT with direct questions (Solomon et al. 2007); RRT with UCT (Coutts and Jann, 2011); RRT with nominative (St. John et al., 2010)	Yes	Proportion of sample population engaging in sensitive behaviour + link to explanatory variables associated with behaviour
Nominative technique (Miller, 1985)	Yes (St. John et al., 2010)	Nominative with RRT and direct questions (St. John et al., 2010)	Yes	Proportion of sample population engaging in sensitive behaviour
Unmatched-count technique (UCT; Droitcour et al., 1991)	Yes (Nuno et al., 2013b)	UCT with direct questions (Tsuchiya et al., 2007); UCT with RRT (Coutts and Jann, 2011)	Yes	Proportion of sample population engaging in sensitive behaviour + link to explanatory variables associated with behaviour
Grouped answer method (Droitcour and Larson, 2002)	No	None	Yes	Proportion of sample population engaging in sensitive behaviour
Crosswise model (CM; Yu et al. 2008), Triangular model (TM; Yu et al. 2008), Diagonal model (DM; Groenitz 2014)	No	CM with direct questions (Jann et al. 2012)	Maybe	Proportion of sample population engaging in sensitive behaviour + link to explanatory variables associated with behaviour
Hidden sensitivity model (HSM; Tian et al., 2007)				
Surveys with negative questions (Esponda and Guerrero, 2009)	No	None	Maybe	Proportion of sample population engaging in sensitive behaviour
Bean method (BM; Lau et al. 2011)	No	BM with direct questions (Lau et al. 2011)	Yes	Proportion of sample population engaging in sensitive behaviour

FIGURE LEGENDS

854 **Figure 1.** An example instruction card for the forced response randomized response technique.
 855 Respondents are provided with an opaque beaker, two dice and a set of question cards each displaying
 856 the instructions. The dice are rolled and the instructions followed. Depending upon how the survey is
 857 administered, respondents provide their answers either by saying ‘yes’ or ‘no’ out load to an
 858 interviewer, or by personally recording their answer. The respondent never reveals the result of the
 859 dice role. Killing a leopard is used here (and in Figures 2 and 3) as an example of an activity of
 860 conservation concern that may be illegal in some study systems.

861 **Figure 2.** An example instruction card for the additive randomized response technique. Respondents
 862 are provided with a cloth sack containing numbered balls with a known distribution. Respondents
 863 select one ball from the sack and add the number shown on the ball to their numeric response to the
 864 question. The respondent never reveals the number displayed on the ball they select. Respondent may
 865 call their answers out load to an interviewer or record them personally.

866 **Figure 3.** Example questions for the nominative technique. This method could be administered
 867 through a face-to-face interview or self-administered using pen-and-paper, or computer. *Randomised
 868 selection requires respondents to write down the initials of each friend and number them from 1 to the
 869 end of the list; predefined instructions (e.g. if the number of close friends reported in question 1 is 5,
 870 ask about friend number 2 on the list) in order to identify which friend they should think about when
 871 answering the sensitive question(s).

872 **Figure 4.** An example of baseline and treatment unmatched-count technique (UCT) lists viewed by
 873 survey respondents randomly allocated to either baseline or treatment groups. Respondents are
 874 required to report the total number of items that apply to them without identifying any individual item.
 875 “Hunting” is used here (and all figures thereafter) as an example of an activity of conservation
 876 concern that may be conducted illegally in some study systems and/or under certain conditions.

877 **Figure 5.** An example of cards used for the grouped answer method. Depending upon the treatment
 878 group they are assigned to, respondents are required to report which group on Card 1 or 2 they belong
 879 to without identifying which items apply to them.

880 **Figure 6.** An example of a question card to be used in studies applying either the crosswise model or
 881 the triangular model. Respondents are asked to provide a joint answer to both questions following
 882 different rules according to specific technique.

883 **Figure 7.** An example of a question card to be used in studies applying the hidden sensitivity model.
 884 Respondents are asked to answer A, B, C or D according to the card instructions; people that have
 885 done any of the sensitive activities are required to answer irrespectively of their actual birthday,
 886 protecting their answers.

887 **Figure 8.** An example of a question card to be used in studies applying the diagonal model. After
 888 being read or shown two questions (one sensitive and the other non-sensitive), respondents should
 889 report the number (1, 2, 3 or 4) in the table that provides the required answer depending on both
 890 questions simultaneously.
