Uses and misuses of the STROBE statement: bibliographic study

Bruno R da Costa,1 Myriam Cevallos,1,2 Douglas G Altman,3 Anne W S Rutjes,1 Matthias Egger1

ABSTRACT

Objectives: Appropriate reporting is central to the application of findings from research to clinical practice. The Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) recommendations consist of a checklist of 22 items that provide guidance on the reporting of cohort, case–control and cross-sectional studies, in order to facilitate critical appraisal and interpretation of results. STROBE was published in October 2007 in several journals including The Lancet, BMJ, Annals of Internal Medicine and PLoS Medicine. Within the framework of the revision of the STROBE recommendations, the authors examined the context and circumstances in which the STROBE statement was used in the past.

Design: The authors searched the Web of Science database in August 2010 for articles which cited STROBE and examined a random sample of 100 articles using a standardised, piloted data extraction form. The use of STROBE in observational studies and systematic reviews (including meta-analyses) was classified as appropriate or inappropriate. The use of STROBE to guide the reporting of observational studies was considered appropriate. Inappropriate uses included the use of STROBE as a tool to assess the methodological quality of studies or as a guideline on how to design and conduct studies.

Results: The authors identified 640 articles that cited STROBE. In the random sample of 100 articles, about half were observational studies (32%) or systematic reviews (19%). Comments, editorials and letters accounted for 15%, methodological articles for 8%, and recommendations and narrative reviews for 26% of articles. Of the 32 observational studies, 26 (81%) made appropriate use of STROBE, and three uses (10%) were considered inappropriate. Among 19 systematic reviews, 10 (53%) used STROBE inappropriately as a tool to assess study quality.

Conclusions: The STROBE reporting recommendations are frequently used inappropriately in systematic reviews and meta-analyses as an instrument to assess the methodological quality of observational studies.

INTRODUCTION

Appropriate reporting concerns the clear and complete presentation of what was planned, carried out and found in a particular study. Inappropriate reporting makes the sound application of study findings into clinical practice difficult, if not impossible. For instance, clinicians are often faced with reports of studies which do not provide enough detail of interventions for them to be implemented in clinical practice. Inadequate reporting may also be a problem for the synthesis of evidence. It is common for systematic reviewers or meta-analysts to...
exclude otherwise eligible studies owing to incomplete reporting. Given the human and financial resources needed to conduct clinical studies, it is clear that inadequate reporting has also important ethical and moral implications.²

To help improve the reporting of key items, reporting guidelines have been developed for various types of research design. The positive effect of reporting guidelines on the quality of reporting has been documented in several reviews.³⁻⁵ The Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) Statement was developed in a collaborative effort of epidemiologists, methodologists, statisticians, researchers and journal editors to improve the reporting of observational studies, including cohort, case–control and cross-sectional studies. The initiative was established in 2004 and subsequently developed in several meeting. STROBE was published in October 2007 simultaneously in several journals including leading biomedical journals such as The Lancet, BMJ, Annals of Internal Medicine and PLoS Medicine. The STROBE recommendations are accompanied by an explanation and elaboration document (E&E) which explains in detail the rationale of each item and provides examples of transparent reporting from published articles. To date, the STROBE Statement is endorsed by over 100 journals as well as by the International Committee of Medical Journal Editors.⁶

The purpose of the STROBE Statement is to ensure clear presentation of what was planned, done, and found in an observational study and the authors of STROBE clearly stress that ‘the recommendations are not prescriptions for setting up or conducting studies, nor do they dictate methodology or mandate a uniform presentation.’⁹ Notwithstanding the clear statement of the purpose of STROBE by its authors, some journal editors are concerned that the STROBE recommendations may be inappropriately used as an assessment tool to judge study quality or that researchers may use STROBE as a guideline to set up or conduct observational studies.¹⁰

In the present study, we examined in which circumstances and context STROBE has been cited by the researchers (how, where and why), and the background of researchers who cited STROBE. We considered the use of STROBE other than in relation to its original purpose as a reporting guideline for observational studies. Our results were presented and discussed during the August 2010 STROBE group meeting, when the group met to discuss a possible revision of the STROBE recommendations in light of the group’s experience, anecdotal reports, feedback from STROBE users and new evidence.

**Methods**

**Literature search**

On 12 August 2010, we conducted a two-step literature search in the Web of Knowledge database (http://www.isiknowledge.com/). The first step consisted of a search for STROBE publications. Our search strategy to identify STROBE publications contained words used in the title of the STROBE article and author name (appendix 1). This first search was conducted in order to set up the second search, where we identified articles which had cited any of the STROBE publications identified in the first step, using the ‘create citation report’ tool available in the Web of Knowledge database.

**Article selection**

Eligibility criteria for our first search (ie, search for STROBE publications) consisted of any STROBE publication regardless of language or version of publication (ie, checklist or E&E). We excluded the Strengthening the Reporting of Genetic Association Studies (STREGA) recommendations, which is an extension of STROBE to genetic epidemiology.

There were no eligibility restrictions for our second search (ie, search of articles which cited STROBE). Any publication type, such as comments, editorials, systematic reviews or observational research, was eligible for inclusion. We then randomly selected a sample of 100 articles from the final list of articles which cited STROBE for detailed assessment.

**Data collection**

We collected the following information for STROBE publications identified through our initial search: journal in which STROBE was published, language of publication and number of citations which STROBE received per year.

For the data extraction from articles which cited STROBE, a data-extraction form was developed by the authors and piloted by two reviewers (BRdC and MC) on a sample of 40 studies which were not part of the randomly selected articles. A single reviewer (BRdC) then conducted data extraction on a randomly selected sample of 100 articles for the following items: verbatim text of sentence(s) which included STROBE citation; reason for citation; STROBE article cited; type of article that cited STROBE (observational research; systematic review or meta-analysis; comment, editorial or letter to the editor; methodological article; or recommendations or narrative review); and background of researchers. Categories for ‘reason of citation’ were defined during the piloting of the data-extraction form, and additional categories were defined during data extraction as necessary. Whenever the data extractor (BRdC) was in doubt about the classification of an article, he discussed it with other authors until a decision was reached. In case of disagreements, the final decision was made by the senior epidemiologist (ME).

**Classification of reasons for citation**

Results of our search for articles which cited STROBE are presented narratively. Our sample of 100 randomly selected articles were classified into eight groups according to reason for citation: STROBE used as a reporting guideline; STROBE used as a methodological (ie, research design or conduct) guideline; STROBE used
We identified 643 citations of STROBE since its publication in 2007, five in 2008 and one in 2009. Table 1 and two in German. Ten of these publications were by da Costa BR, Cevallos M, Altman DG, pub.

RESULTS
Search for STROBE publications
We identified 16 STROBE publications. Eleven of these publications were published in English, three in Spanish and two in German. Ten of these publications were published in 2007, five in 2008 and one in 2009. Table 1 displays the journals where STROBE was published, the number of citations received, the impact factor of the journal, the language of the publication and the date of the publication.

Search for articles which cited STROBE
We identified 643 citations of STROBE since its first publication in October 2007 until August 2010. Two-hundred and four citations (32%) concerned the STROBE E&E document, and 439 (68%) citations concerned the STROBE checklist. The STROBE checklist published in The Lancet was the most cited, receiving 110 (17%) citations. The number of citations was associated with the impact factor of the journal as shown in table 1, the main exception being the Journal of Clinical Epidemiology, which received a large number of citations despite a lower journal impact factor.

Half of the articles in our sample of 100 randomly selected articles were observational studies (32%) or systematic reviews/meta-analyses (19%). Table 2 displays the characteristics of these 51 research articles identified in our random sample.

Comments, editorials and letters accounted for 15% of the articles, methodological articles for 8%, and recommendations and narrative reviews for 26%. Of the 32 observational studies assessed, 26 (81%) made an appropriate use of STROBE, and three (10%) uses were considered inappropriate. Of the 19 systematic reviews or meta-analyses assessed, 10 (53%) made an inappropriate use of STROBE. Thus, of the 51 research articles, 26 (51%) used STROBE appropriately, and 13 (25%) used STROBE inappropriately.

Box 1 Text examples of appropriate and inappropriate use of Strengthening the Reporting of Observational Studies in Epidemiology (STROBE)

Based on the original purpose of STROBE, we consider the following text examples as appropriate or inappropriate use of STROBE

**Appropriate**
- ‘The reporting of this study conforms to the STROBE statement.’³¹
- ‘The STROBE guidelines were used to ensure the reporting of this observational study.’³²
- ‘The paper is reported following the STROBE statement.’³³

**Inappropriate**
- ‘This prospective study was designed following recommendation of the STROBE statement.’³⁴
- ‘The analysis followed the principles of the Strengthening the Reporting of Observational Studies in Epidemiology initiative.’³⁵
- ‘The quality of selected studies was assessed using a modified version of the STROBE statement. …The STROBE was modified by adding questions about the serologic method used to confirm dengue diagnosis, use of viral isolation, and whether the study was based on a single dengue outbreak or dengue season. Use of viral isolation increased the score whereas single outbreak studies received no additional points. The quality score was the number of items from the STROBE checklist addressed as a percentage of the total number of items applicable (minimum of 23 and maximum of 25). Studies with a quality assessment below 50% were excluded.’³⁶
Finally, out of the 26 studies which used STROBE appropriately, 13 (50%) had authors affiliated with epidemiology or public-health departments, compared with six (46%) among the 13 studies with inappropriate use of STROBE. As for the 10 systematic reviews that inappropriately used STROBE as a tool to assess study quality, none were published in the Cochrane Database of Systematic Reviews, nine were published in medical specialist journals, five had at least one of the authors affiliated with epidemiology or public health departments, and all were published in English. The 10 articles related to cardiology, endocrinology, psychology, neurology, paediatrics, ophthalmology, internal medicine, periodontology, pharmacology and infectious diseases.

DISCUSSION

STROBE has been cited over 600 times since its publication in 2007. Our citation analysis showed that most of the observational studies used STROBE as a guideline for reporting, whereas about half of the systematic reviews and meta-analyses used STROBE inappropriately, as a methodological quality-assessment tool.

The inappropriate interchangeable use of the terms ‘methodological quality’ and ‘reporting quality’ is common and may explain why some researchers used STROBE as a tool for the assessment of methodological quality or as a guideline to design and conduct observational research. Reporting quality refers to the completeness with which a study is presented and whether major items for the proper appraisal of internal and external validity of findings are clearly reported. Methodological quality refers to the appropriateness of the methods employed in the design and conduct of epidemiological research, which determines the reliability of findings (ie, internal validity).

Even though the authors of STROBE clearly state that its purpose is to guide reporting of observational research, we found that it is commonly used as a methodological quality-assessment tool in systematic reviews.

*This category includes observational studies which cited STROBE as a guideline without making it clear whether the guidance related to reporting or methodology, or articles which mentioned STROBE in a commentary.
and sometimes as a guideline to design and conduct observational studies. Some journal editors have expressed concern that the STROBE recommendations may be inappropriately used as an assessment tool to judge study quality, or that researchers may use STROBE as a guideline to set up or conduct observational studies. Our results show that these concerns were justified, although we feel that some items of STROBE might be useful when designing or conducting an observational study. In particular, the explanation and elaboration STROBE document (E&E) could be useful to inform methodological decisions, especially for researchers with little formal training in epidemiology.

Although some items of STROBE may be related to risk of bias, many of the items are exclusively related to transparent reporting. For instance, the first item of STROBE asks researchers to indicate in the title of their manuscript the design of their study. Obviously, whether authors report the design of their study in the title of their manuscript will not influence the effect estimates of their study or compromise the generalisability of their findings. To illustrate the pitfalls of using STROBE as a methodological assessment tool, we refer to the last text example we provided as an example of inappropriate use of STROBE in box 1. In this example, the authors of a systematic review transformed STROBE into a scale by assigning scores to each of its items, and a final score was used to determine the eligibility of studies for inclusion into the systematic review. By doing so, authors may have introduced bias to their findings, as different tools used to score methodological quality may result in different conclusions regarding the overall appropriateness of the methods employed in a particular study.

The misuse of STROBE as a tool to assess methodological quality may be explained by the lack of validated and accepted tools for such assessments. As a consequence, authors who want to assess methodological quality of studies may turn to reporting guidelines. The absence of reliable tools that are based on sound empirical evidence to assess the quality of observational studies was documented by Sanderson et al. in 2007.

There is an extensive literature indicating that the misuse of findings of scientific articles is common across different fields of healthcare. In a similar analysis, Moher et al. reported that the Consolidated Standards of Reporting Trials statement, a reporting guideline for randomised controlled trials, has also been misused by 4–10% of assessed articles as a guideline for quality assessment. Taken together, these results indicate a failure of not only authors but also peer-reviewers in recognising and avoiding misuse of guidelines. The peer-review process should ideally prevent misuses that are of major concern, in particular when misuses may dictate the outcomes of research as discussed above.

We observed an association between the numbers of citations received and the impact factor of the journal in which STROBE was published. Even though the contents of many STROBE publications are identical, researchers preferred to cite a STROBE article published in a journal with a higher impact factor. This association was also observed by Perneger, who concluded that citations received by an article are not merely explained by scientific merit. Although reasons directing authors’ choices are not clear, for some, a high impact factor may suggest the acceptance by a broader audience. The main exception to this association was the STROBE checklist published by the Journal of Clinical Epidemiology, which was also highly cited. This may have occurred because STROBE is particularly relevant for the daily work of the readers of this journal.

We found no clear pattern regarding affiliations of authors to an institution with a methodological focus. In particular, we found no difference in affiliations between authors who used STROBE appropriately and authors who used STROBE inappropriately. Similarly, no clear patterns emerged when we examined more closely the characteristics of the 10 systematic reviews that inaccurately cited STROBE.

A limitation of our findings is the fact that we included only articles which cited STROBE. This may have resulted in selection bias, since some researchers may have used STROBE for their study but not formally cited it. Such studies could not be identified by our search strategy. However, it is unclear to us in which direction this possible selection bias may have influenced our findings.

Citations to the STROBE checklist have been steeply increasing since its first publication. STROBE is commonly used according to its original purpose, that is, a reporting guideline of observational research. However, despite the clear statement of its objective by its authors, STROBE is misused by some researchers reporting observational studies and about half of authors reporting systematic reviews, because they used it either as a tool to assess methodological quality or as a guideline on how to design and conduct observational studies. Further studies are required to define the consequences of the inappropriate use of reporting recommendations in clinical and epidemiological research, in particular the use of these checklists as an instrument to assess the methodological quality of studies.

Funding BRdC is supported by a grant from the ARCO Foundation, Switzerland. STROBE is supported by the Swiss National Science Foundation and the Schweizerische Akademie der Medizinischen Wissenschaften.

Competing interests BRdC, MC, DGA, and ME are members of the group revising the STROBE statement.

Contributors All authors conceptualised the ideas in the manuscript, and read and approved the manuscript. BRdC developed the first draft and incorporated comments from authors for successive drafts. BRdC is the guarantor of this study.

Provenance and peer review Not commissioned; externally peer reviewed.
