Abstract. Soil salinity management can be complex, expensive, and time demanding, especially in arid and semi-arid regions. Besides taking no action, possible management strategies include amelioration and adaptation measures. Here we apply the World Overview of Conservation Approaches and Technologies (WOCAT) framework for the systematic analysis and evaluation and selection of soil salinisation amelioration technologies in close collaboration with stakeholders. The participatory approach is applied in the RECARE (Preventing and Remediating degradation of soils in Europe through Land Care) project case study of Timpaki, a semi-arid region in south-central Crete (Greece) where the main land use is horticulture in greenhouses irrigated by groundwater. Excessive groundwater abstractions have resulted in a drop of the groundwater level in the coastal part of the aquifer, thus leading to seawater intrusion and in turn to soil salinisation. The documented technologies are evaluated for their impacts on ecosystem services, cost, and input requirements using a participatory approach and field evaluations. Results show that technologies which promote maintaining existing crop types while enhancing productivity and decreasing soil salinity are preferred by the stakeholders. The evaluation concludes that rainwater harvesting is the optimal solution for direct soil salinity mitigation, as it addresses a wider range of ecosystem and human well-being benefits. Nevertheless, this merit is offset by poor financial motivation making agronomic measures more attractive to users.

1 Introduction

Soil, as a control on the biogeochemical and hydrological cycles of the Earth system and a provider of vital goods and services to sustain life, is one of our most important natural resources (Berendse et al., 2015; Brevik et al., 2015; Keesstra et al., 2012). Soil salinisation – a term used to refer comprehensively to saline, sodic, and alkaline soils (van Beek and Tóth, 2012) – is one of the major soil degradation threats globally, especially in drylands. In advanced stages salinisation transforms fertile and productive fields to barren land, thus restraining any vegetation growth (Chesworth, 2008; Jones et al., 2012; Tóth et al., 2008). High levels of soil salt accumulation can impact agricultural production, environmental health, and economic welfare (Rengasamy, 2006). Globally, 34 Mha – about 11 % of total irrigated land – is estimated to be impacted (Montanarella, 2007). Salinisation is often linked to arid irrigated lands where prevailing low rainfall, high evapotranspiration rates and soil characteristics impede soil leaching, thus causing salt to accumulate in the upper layers (Chesworth, 2008; Maas et al., 1999; Mateo-Sagasta and Burke, 2011). While moderate problems are reported even when irrigating with water of sufficient quality, constant or increasing soil salinity is chiefly caused by the use of highly saline irrigation water such as groundwater suffering from seawater intrusion (Dubois et al., 2011; Geeson et al., 2003; Mateo-Sagasta and Burke, 2011; Tóth and Li, 2013; van Camp et al., 2004).

Soil salinity is a major factor limiting crop production and land development in coastal areas (Li et al., 2012; Sparks, 2003) and is a major cause of desertification in the Mediter-

anean countries. Along the Mediterranean coast, the problem of soil salinity is increasing due to scarcity of precipitation and irrigation with low-quality water. Saline soils here are present mainly due to human activities (Abu Hammad and Tumeizi, 2012; Domínguez-Beisiegel et al., 2013), especially with the extension of irrigation and the unmanaged use of saline water. In the Mediterranean region, 25 % of irrigated agricultural land is affected by a significant level of salinisation leading to soil degradation (Geeson et al., 2003; Mateo-Sagasta and Burke, 2011). Water supply in Greece is largely derived from groundwater sources, and about 9 % of the approximately 1.4 Mha of irrigated land is affected by soil salinisation due to seawater intrusion (Jones et al., 2003; OECD, 2009). Seawater intrusion in most coastal areas of Greece has progressed a great distance inland, especially in the south, which is characterised by a more arid climate (Daskalaki and Voudouris, 2008). The island of Crete (Fig. 1) is no exception to the problem, with intensive agriculture and high tourism activity being the two prime factors that strongly impact upon the available water resources. Agricultural growth in the Messara Plain of Crete has significantly impacted the water resources and ecosystem services of the area by substantially increasing groundwater demand (Daliakopoulos and Tsanis, 2014). The problem is exacerbated by poorly managed or unmanaged groundwater extraction and distribution as well as arid climatic conditions. Seawater intrusion in the coastal aquifer of Timpaki (Paritsis, 2005; Vafidis et al., 2013) adversely affects both water resources and soil.

Sustainable land management (SLM) solutions for the problem of soil salinisation largely depend on water availability, climatic conditions, period of salinity, land use and type of assets under threat, the current extent and rate of the threat, and the availability of resources (capital, inputs). Measures can be applied in conjunction with a wide range of amelioration methodologies (Ali, 2011; Qadir et al., 2000) which can nevertheless be very case specific. A brief account of such methodologies towards soil and water sustainability is presented in Table 2. The adoption of SLM practices depends on personal, sociocultural, socio-economic, institutional, and biophysical factors (Illukpitiya and Gopalakrishnan, 2004) rather than technical ones (Kessler, 2006). The range of variables that affect adoption may have contrasting effects depending on context (Liu et al., 2013), and while economic incentives (e.g. Posthumus and Morris, 2010) and accounting for risks, effectiveness, time, and effort involved in implementation strongly influence SLM technology adoption (e.g. Sattler and Nagel, 2010), subjective user preference may be equally or more important (e.g. Wauters et al., 2010). The World Overview of Conservation Approaches and Technologies (WOCAT, 2008) global network has been established to assist SLM specialists and practitioners from all over the world in sharing valuable knowledge and improving decision-making concerning alternative SLM practices (Liniger and Critchley, 2007; Schwilch et al., 2011),

thus eventually facilitating SLM adoption. A review of the WOCAT database reveals that 10 out of 11 documented measures for soil salinity amelioration or adaptation cover agronomic, vegetative, or management rather than structural measures (WOCAT, 2015). While this is by no means a representative sample, it points to a preference of the stakeholders for low-cost, decentralised, and self-sustained solutions. Besides, stakeholder-inclusive decision making against soil salinity is currently gaining popularity (e.g. Bowmer, 2014; Hornidge et al., 2011; Lázár et al., 2015; Schultz et al., 2007) around the world. Through global sharing of successful (or failed) SLM experiences by researchers, technicians, planners, and end users involved in combating soil degradation, WOCAT strives to augment efficiency in the application of knowledge and funds for improved decision making and optimised land management.

The RECARE (Preventing and Remediating degradation of soils in Europe through Land Care) FP7 project aims to develop effective prevention, remediation, and restoration measures using an innovative transdisciplinary approach, actively integrating and advancing knowledge of stakeholders and scientists in 17 case studies, covering a range of soil threats in different biophysical and socio-economic environments across Europe. RECARE uses WOCAT to identify prevention, remediation, and restoration measures currently used to combat soil salinisation in Greece (among other soil threats at 16 other European sites). In this context, and towards an interdisciplinary approach on soil research (Brevik et al., 2015), this work assesses and discusses a stakeholder involving selection process for the application of promising technologies for soil salinity amelioration, focused at greenhouses cultivations of Timpaki, Crete.

2 Methodology

2.1 The WOCAT Technology Questionnaire

The WOCAT Technology Questionnaire (QT) defines SLM technologies as “agronomic, vegetative, structural and/or management measures that prevent and control land degradation and enhance productivity in the field”. These solutions may include mechanical structures (e.g. terraces, check dams, contour stone walls, and contour ridges), biological structures (e.g. afforestation and strips of vegetation), manipulation of the surface soil (e.g. tillage; mulching; and soil amendments such as surfactants, compost, and animal and green manure), rainwater harvesting (e.g. reservoirs and retaining dams), agronomic measures (e.g. drought-resistant species and varieties, short-cycle varieties, crop rotation, animal and green manures, appropriate fertiliser use, compost, and weed control), and management measures (e.g. timing and intensity of agricultural activities, grazing management).

The QT describes case studies from the field and is always linked to a specific area where the technology is ap-

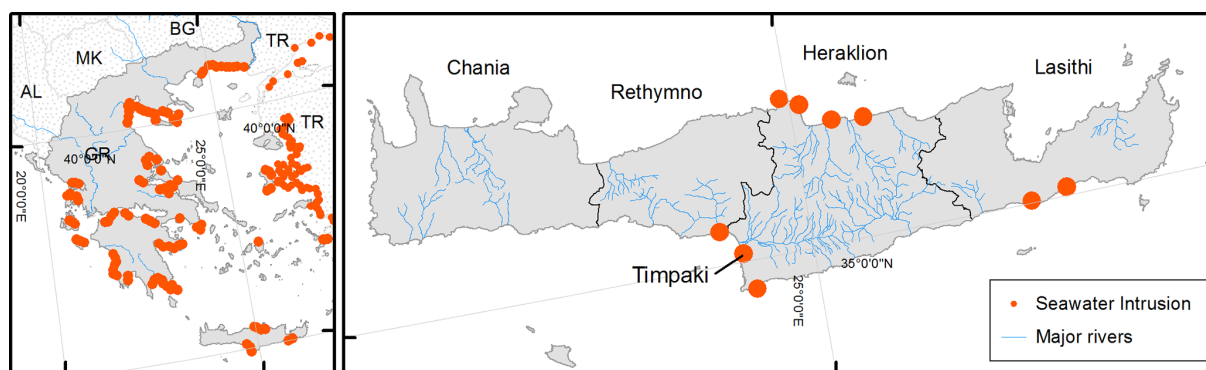

Figure 1. Areas of seawater intrusion in Greece (left) and specifically in Crete (right). Adopted from Daskalaki and Voudouris (2008) and EEA (1999).

plied and to SLM specialists who provide the information. It addresses the specifications of the technology (purpose, classification, design, and costs) and the natural and human environment where it is used. It also includes an analysis of the benefits, advantages and disadvantages, economic impacts, acceptance, and adoption of the technology (Schwilch et al., 2009). The collection of information involves personal contacts and knowledge sharing between land users and SLM specialists. The immediate benefits of filling in the questionnaires include the compilation of fragmented information – often consisting of the undocumented experiences of land users and specialists – and a sound evaluation of one’s own SLM activities (Liniger and Schwilch, 2002) so that they can be retrieved and suggested under similar biophysical, socio-economic, and institutional conditions.

2.2 Stakeholder interaction

The stakeholder interaction methodology presented here starts with a participatory identification of actual and potential prevention, remediation, and restoration measures during a stakeholder workshop where a first selection of promising measures is made. At this workshop, participating scientists also propose soil salinisation prevention/amelioration measures documented in the literature (adopted to the case study conditions) to ensure sufficiently sound alternatives are available, while stakeholders provided measures from their personal experience. Feasible and promising measures are singled out during the workshop, and WOCAT questionnaires for SLM technologies are used to document them. Knowledge gaps and ambiguities are clarified via personal communications with experts.

At a subsequent workshop documented technologies are presented in depth and a list of possible local and scientific criteria are identified in collaboration with stakeholders. Criteria are grouped by the technology’s benefit or impact categories, as depicted by WOCAT: (a) production and socio-economic, (b) sociocultural, (c) ecological, and (d) off-site benefits. Eventually, criteria of each category are ranked from

the least to the most important according to stakeholder perception. Prominent technologies are also assigned scores per criterion for their expected effects on reducing soil degradation, related costs and benefits, and ecosystem services, also reflecting the degree to which these technologies are acceptable by stakeholders.

2.3 Technology evaluation and selection

A simplified version of the multi-criteria analysis (MCA) described in Mendoza et al. (2000) is used for the evaluation of each technology t considering a set of criteria c which, under the premise of the previous paragraph, fall within a single criteria category. Considering that criteria are ranked in ascending order of importance (i.e. 1 is the least important and n is the most important of n number of criteria), weights (W_c) can be assigned so that $\sum_{c=1}^n W_c = 1$. Per criterion, a technology is assigned a score ($S_{c,t}$) which is taken into account weighted by W_c to estimate the cumulative score S_t , such that

$$S_t = \sum_{c=1}^n W_c \times S_{c,t}. \quad (1)$$

The result of this weighting allows technologies to be ranked per benefit category, assuming that categories themselves cannot be directly compared. For example, here we consider that, e.g., off-site benefits cannot be measured against sociocultural benefits, so a unique S_t is calculated per benefit category. In an effort for parsimony, here we ignore several aspects of decision analysis uncertainty (Scholten et al., 2015).

3 Case study

The Timpaki Basin is connected to the western Messara Plain by the Geropotamos River through the Phaistos Gorge and encompasses an area of 50 km² located in the central-south

area of Crete with a mean elevation of 200 m. The topography of the basin is generally flat with steeper slopes in the northeast, with the highest point being part of the Psiloritis Mountain (Fig. 1). The climate ranges between sub-humid Mediterranean and semi-arid with mild moist winters (average temperature: 12 °C) and dry hot summers (average temperature: 23 °C), while the mean annual precipitation is around 500 mm. As there is little surface water flow outside the winter months (Vardavas et al., 1997), groundwater is the main source of irrigation water and the key resource controlling the economic development of the region. Water shortage often occurs, due to temporal and spatial variations of precipitation, increased water demand during summer months, and the difficulty of transporting water due to the mountainous areas. Lately, there have been growing concerns over the possible depletion or deterioration of the groundwater quality due to intensive pumping beyond the safe yield of the basin (Tsanis and Apostolaki, 2008) and the gradual seawater intrusion (Paritsis, 2005; Vafidis et al., 2013). Despite measures for the protection of water resources imposed by the local water authority since 1984, implementation has faced difficulties mainly due to private wells (Kritsotakis and Tsanis, 2009).

Because of the favourable climatic conditions year-round, Timpaki is a highly exploited area concerning the greenhouse cultivations, even compared to the parent municipality of Phaistos (Table 1). Horticultural crops are drip-irrigated almost exclusively from groundwater extraction; harvested twice a year; and mainly comprised of tomato (*Solanum lycopersicum*), cucumber (*Cucumis sativus*), zucchini (*Cucurbita pepo*), eggplant (*Solanum melongena*), pepper (*Capsicum annuum*), and green beans (*Phaseolus vulgaris*) (Thanopoulos et al., 2008). Here we address only tomato, the prevailing and most profitable horticultural crop under plastic. Tomato is moderately sensitive to salinity, able to withstand soil electrical conductivity (EC) up to 2.5 dS m⁻¹ without significant yield losses (~ 10 %) but suffering a 50 % yield loss at 5.0 dS m⁻¹ (Jones Jr., 2007).

Contrary to many rural areas in Greece that face the effects of urbanisation, the population of Timpaki has been steadily rising since the 1950s, mainly due to the opportunities offered by the tourism sector in this coastal area (Fig. 2, left). Furthermore, there is evidence that suggests a motion of rural repopulation may have been activated in the country (Gkartzios and Scott, 2015). In Timpaki, land is mostly privately owned, and water rights can be public, cooperative, or private. The socio-economic gap among farmers is not too wide and more or less on par with those of the rest of the community which has faced a prolonged crisis leading to little overall investments and financial contraction (Fig. 2, right). Stakeholders often hold more than one role in the community, which often facilitates confrontation, either perpetuating or forcing conflicts to be resolved.

3.1 Participatory selection of SLM technologies

In the context of the RECARE project, Timpaki has been selected as a case study of the salinisation soil threat. As part of the stakeholder participation and valuation activities, 20 local and external stakeholders (including local and prefectural administrative authorities, agricultural technicians, farmers, scientists, and NGO representatives) participated in a local workshop in February 2015. Stakeholders were asked to (1) identify and group the primary constraints of greenhouse production linked to soil salinisation and to (2) discuss the list of potential technologies for addressing the soil salinisation threat from a user's point of view and select the most promising technologies currently applied. Criteria for selection included compatibility with current agricultural practices as well as sustainable investment and maintenance cost.

At a second workshop, stakeholders were invited to (1) assess promising technologies using criteria from the WOCAT QT and (2) reach a consensus regarding the perceived ranking of criteria of the same category. Through this process, promising technologies were assessed and selected using a participatory approach that combines collective learning with the application of a globally standardised documentation and evaluation framework as well as follow-up communication with experts. Table 2 presents a comprehensive list of empirical and literature prevention and amelioration technologies that have been applied to combat the soil salinisation threat, along with a representative reference. Table 2 also lists the type of measure according to WOCAT classification as well as the main prevention/amelioration strategy addressed by the respective technology (explained in Table 3). The next paragraphs thoroughly discuss the three most prominent technologies that surfaced from the participatory selection of the technologies listed in Table 2. These technologies were selected among already-applied approaches that were unanimously considered by stakeholders as “best practices” for greenhouse cultivation in the area.

3.2 Technology 1 (T1): rainwater harvesting from greenhouse roofs

Rainwater harvesting is one of the most ancient soil and water conservation and management technologies (AbdelKhaleq and Alhaj Ahmed, 2007). Nevertheless, applications are still current, often taking advantage of greenhouse structures (Islam et al., 2013; Ji et al., 2010) and explicitly practiced against soil salinity in greenhouses (Davies et al., 2011). The technology involves taking advantage of greenhouse roofs used as catchment areas for rainwater harvesting. Harvested rainwater is used for irrigation, either on its own or mixed with water from other sources. A network of gutters is installed to channel water into a storage tank that can be either above ground or at ground level, open or covered (Fig. 3). Reservoir size may be determined by various criteria, but the rule of thumb in the area is to construct

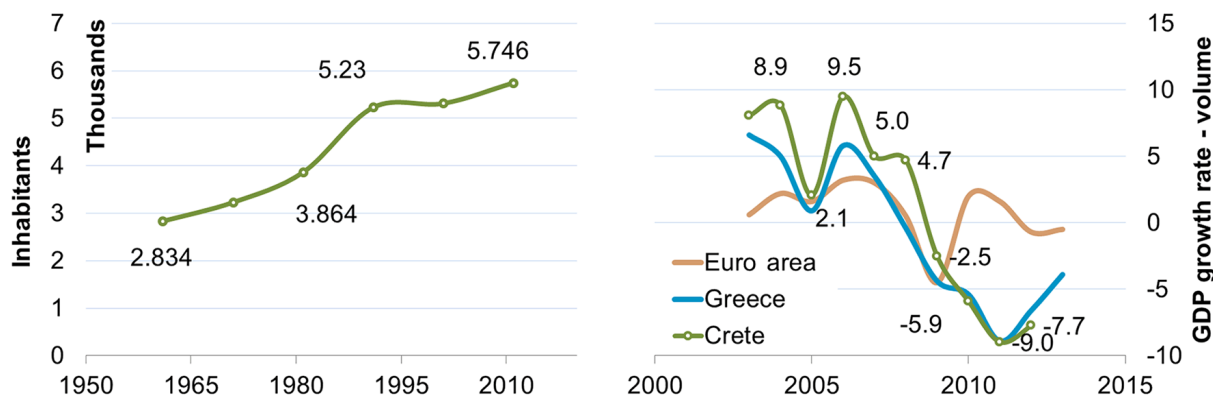

Figure 2. Left, population in Timpaki (Source: HSA, 2015); right, “real GDP growth rate – volume – percentage change on previous year” for the Euro area, Greece, and Crete (Source: EUROSTAT, 2015; HAS, 2015).

Table 1. Units in ha (% of total). Source: HSA (2008).

Area	Olive trees	Arable crops*	Horticulture	Citrus	Vine trees	Total
Timpaki	1100 (43 %)	1005 (39 %)	401.5 (16 %)	37 (1 %)	3 (0 %)	2540.2
Phaistos	13 090 (79 %)	1805 (11 %)	1404.3 (8 %)	187.5 (1 %)	62.4 (0 %)	16 549.2

* Major arable crops include watermelons, melon, and potatoes.

300 m³ ha⁻¹ of greenhouse area. A cover may also be installed to reduce evaporation. Furthermore, a suitable pump and mixing facilities are installed to control water quality and quantity. During operation, a water filter and/or other water treatment may be required for removal of particles and waterborne-disease mitigation.

The technology promotes sustainable land management through prevention and mitigation of land degradation by increasing water resource self-sufficiency, thus allowing the user to rely less on the scarce groundwater resources and reducing the risk of soil salinisation and production failure. Furthermore, the technology improves the overall irrigation water quality, both on- and off-site. The main disadvantage of the technology, especially for the cultivation of tomatoes, which require irrigation water of moderate electric conductivity, is the increase of compensating agricultural inputs (i.e. fertilisers). This disadvantage can be mitigated by mixing freshwater with water from lower-quality sources (e.g. Malash et al., 2005). The technology requires average technical knowledge from both the agricultural advisor and the land user. Establishment costs include the construction of the preparation of the tank placement surface, the tank construction, the installation of the gutter network, and the installation of the pump and water sanitation measures. The majority of the greenhouses in the region have built-in gutters between the basic construction units in order to discharge rainwater from the roof for structural safety. Thus, few additional structural measures are required besides the construction of a reservoir system, such as a PVC-lined aboveground

tank or artificial pond. Maintenance costs of the gutter network, the water storage tank, and the pump are negligible. Total costs amount to approximately EUR 14 000 ha⁻¹ for a water storage that can cover at least 50 % of the irrigation demand throughout the year, but this can vary depending on scale.

3.3 Technology 2 (T2): crop rotation for green manuring in greenhouse

Green manuring is also part of our global heritage of ancient agricultural practices (MacRae and Mehuys, 1985) and has been regaining attention as an organic farming soil amendment. The positive effects of green manuring on open-field vegetables are well documented (Beckmann, 1977; Chaves et al., 2004; MacRae and Mehuys, 1985; Stirling and Stirling, 2003; Thorup-Kristensen, 2006) and followed by modern greenhouse applications (Aghili et al., 2014; Duyar et al., 2008; Rose et al., 2015; Tüzel et al., 2013). Here, the angiosperm *Sorghum vulgare* used in greenhouse cultivations is suggested as green manure through crop rotation with tomato plants. The crop rotation usually takes place every other summer when local greenhouses remain otherwise fallow. Initially, when the main crop (tomatoes) is removed from the greenhouse in May/June, about 70 kg ha⁻¹ of sorghum seeds are sown and incorporated into the soil by ploughing at about 4–5 cm depth. Sorghum is drought- and heat-tolerant as well as moderately salt-tolerant (Netondo et al., 2004); thus the irrigation needs are minimal and depend on the respective climatic conditions. Water stress conditions may adversely

affect grain production but promote root system expansion; thus improving soil structure is in this case favourable. Before the beginning of the tomato season in September, the farmer uses a branch grinder to fitter the sorghum plants and then incorporates them into the soil by tillage (Fig. 4). At this time the sorghum is still at a soft dough stage (Vanderlip, 1993), so a 20 cm deep tillage is enough to dispatch the rooting system, and immature grains will not grow back in the greenhouse. The process also needs to be well scheduled to provide enough time for greenhouse sanitation before planting tomatoes.

The technology is applied as an effective agronomic measure for the increase of soil productive capacity, the reduc-

tion of pests and soil-borne parasites such as nematodes (Gardiano et al., 2014; Ortiz et al., 2015), and the mitigation of soil salinity (Netondo et al., 2004). This technology mitigates and prevents soil degradation by improving the soil and subsoil structure through the deep root system of sorghum (often > 1 m for mature crops) and increasing nutrient and organic matter availability through the incorporation of the plant biomass into the soil by tilling it under. Furthermore, organic amendments favour soil hydrology and structure (Yazdanpanah et al., 2016), thus mitigating salt accumulation in the root zone. The technology requires little technical knowledge from both the agricultural advisor and the land user. The increase of workload and the demand of

Figure 3. A network of gutters (a) channels rainwater into a reservoir facility (b) that can be optionally covered (c). The stored water is then pumped (d) into a mixing tank (e) where it dilutes the saline groundwater pumped from the aquifer (f). Reduced-salinity water is then directed to the irrigation system (g) of the greenhouse.

irrigation water during the dry summer period constitute the main drawbacks of this technology. Otherwise, it has negligible establishment costs in the sense that it can be part of the usual farming practices but requires maintenance and recurrent activity costs such as seed and sowing costs, irrigation,

and machine hours for reducing branch length with a branch grinder and incorporating sorghum into the soil with a tiller, which can amount to EUR 1000 ha⁻¹ every 2 years mainly due to labour (i.e. for small-scale farmers personal effort is usually sufficient for the application of the technology, and the only cost is that of seeds and machine rental, or about EUR 200 ha⁻¹).

3.4 Technology 3 (T3): application of biological agents to increase crop resistance to salinity

The *Trichoderma* spp. fungus and various types of symbiotic associations of *mycorrhizae* are used in greenhouse cultivations in order to mitigate the impacts of salinity on crops and to improve existing soil properties. These biological agents are supplied commercially as soil amendments, and specific treatments vary according to cultivation type. The implementation of biological agents usually takes place once per plant as the microorganisms coexist with the plant (symbiotic association) and can be performed in different stages of the crop cultivation, depending on the commercial product, e.g. as a solution in the irrigation water; as a solid soil amendment in the early growing stages (Fig. 5); or, optimally, at the plant

Figure 5. Mycorrhiza supplement in the form of grey aggregates used during tomato transplantation.

nursery (seed bio-priming) or during planting (plant inoculation). Biological agents require increased organic matter in the soil; absence of toxic substances (e.g. copper, fungicides, and pesticides); and, depending on agent type, suitable soil moisture and temperature. Here we investigate the effects of biological agents in tomato plantations, which are implemented in the early growing stages through irrigation.

The technology is applied as an effective agronomic measure for the increase of plants' salt tolerance, the reduction of soil-borne diseases that affect plant roots, and increase of water and nutrient absorption. This technology prevents or mitigates soil degradation by improving the subsoil structure by causing plant root system expansion and increase of the ability of the plant to absorb phosphates and micronutrients (Altomare et al., 1999). This effect can potentially decrease agricultural inputs (water and fertilisers) up to 40%. An additional benefit is the maintenance and increase of subsoil fauna diversity and the subsequent biodegradation. The improved soil structure promotes higher infiltration rates, mitigates the salt accumulation in the root zone, and combats soil salinity, one of the main soil degradation problems in the coastal zone. Finally, the application of biological agents helps to keep the plants healthy, thus leading to increased crop yield and reduced production risk. The technology requires high technical knowledge on the part of the agricultural advisor but little from the side of the land user. The technology has negligible establishment costs since it can be part of the usual farming practices but requires the recurrent activity costs of inoculation with the selected biological agent. For an annual application of a biological agent the total cost is on average EUR 3000 ha⁻¹ year⁻¹ depending on expert advice.

4 Results and discussion

4.1 Technology evaluation

A first interpretation of results (Table 4) shows that T1 is the only technology that directly contributes to the reduction of soil salinity, whereas T2 and T3 have an indirect effect but also act as soil amendments, thus enhancing other soil functions in the process. Due to the immediate effect of fresh-water application, it is safe to say that rainwater harvesting (T1) is the scientifically and ecologically optimal solution for conditions of extremely saline soil, whereas T2 and T3 do require some levels of soil fertility in order to produce results. The use of rainwater harvesting (T1) provides a degree of water autonomy, thus providing farmers with a sense of security for optimising or diversifying production. Additional value is derived by conflict mitigation within the community through the off-site benefit of overall increase of water availability. Disadvantages include soil sealing of fertile soil, thus reducing cultivated space, and the contingency on climatic conditions (precipitation/evaporation). Nevertheless, the latter is minor since during dry years the storage tank can be used as a basic buffer for other sources of water, and the application of covers, shading solutions (Hassan et al., 2015), or wind shelters (Hipsey and Sivapalan, 2003) can reduce evaporation. The significant reservoir installation cost and accommodation are the limiting factors and indeed the largest deterrent, especially for small-property owners. The economic feasibility of rainwater harvesting for irrigation has also been investigated by Liang and van Dijk (2011), who highlighted the importance of low pricing of groundwater that can render the investment in small and medium rainwater-harvesting systems less attractive. Under the current circumstances, the net profit from this investment may be positive only for large-property owners or after long-term use. It is estimated that only 5% of land users in the area own a water-harvesting system and about 70% have constructed it using external material support. Nevertheless, if groundwater and soil salinisation become prohibitive for cultivation, it is certain that a rainwater-harvesting system per greenhouse will no longer be optional.

The use of green manuring (T2) effectively decreases the required amounts of fertilisers and pesticides, therefore leading to a healthier soil in a sustainable way. Based on the practical experience, the cost of the technology is more or less self-sustained (i.e. the additional costs and workload are compensated by the reduced agricultural inputs during the growing season). The requirement of machinery (branch grinder, tiller) that is not used full-time for greenhouse operations (therefore their purchase cannot be easily justified for a small land owner) is viewed as a disadvantage that is hard to overcome if this machinery is not readily available for lending or renting. Moreover, the technology increases workload during a period where the greenhouse is otherwise fallow and would allow a part-time farmer to earn an off-

Table 4. Comparison of the ecosystem and human well-being impacts of each technology along with average ranking of each benefit according to stakeholders.

	Rank	Weight (W_B)	T1	T2	T3
Production and socio-economic benefits					
Increased irrigation water availability quality	4	0.19	+++		
Reduced risk of production failure	5	0.24	++		++
Increased crop yield	3	0.14	+	+	++
Reduced expenses on agricultural inputs	6	0.29	---	+	++
Reduced workload	1	0.05		-	
Reduced demand for irrigation water	2	0.10		-	++
Socio-cultural benefits					
Conflict mitigation	1	0.33	++		
Improved food security/self-sufficiency	2	0.67	+		
Ecological benefits					
Increased water quantity/quality	9	0.20	+++		
Improved harvesting/collection of water	7	0.16	+++		
Reduced soil salinity	8	0.18	+++	+	+
Increased biomass above-ground C	4	0.09		++	+
Increased nutrient cycling recharge	6	0.13		++	
Increased soil organic matter/below-ground C	5	0.11		++	+
Increased soil moisture	3	0.07		+	
Increased biological pest/disease control	1	0.02		+	++
Increased beneficial species (soil biodiversity)	2	0.04			+++
Off-site benefits					
Increased water availability	1	1.00	++		

(+++): very positive; (++): moderately positive; (+): slightly positive; (-): slightly negative; (---): moderately negative; (---): very negative.

farm income (e.g. from tourism). It is worth mentioning that only one farmer in the area practices this technology and had the opportunity to present it to other stakeholders during the workshop. From their side, stakeholders found the technology and its conveyed results very promising and worth further investigation to better identify adoption benefits.

The use of biological agents as crop growth and salinity tolerance amendments (T3) greatly improves crop production and overall soil functions. Significant advantages of this technology include the wide variety of biological agents, and their versatility and adaptability (Harman et al., 2004) that allow technicians to tailor application to the specific needs of each cultivation and user. The technology is simple to implement and generates little additional workload for the end user. Even though the cost of the inoculated plants or respective soil amendments is significant, the technology is applied by at least 15 % of the local users, thus underlining the fact that annual benefits balance out costs. The local farmers' union may provide the opportunity to scale down high initial costs by placing bulk orders.

4.2 Criterial importance and scoring

A second reading of the results based on individual criterial importance reveals a different narration. Reduced expenses on agricultural inputs and risk of production failure predominate other production and socio-economic criteria in the value system of stakeholders (Table 4). This preference largely counterbalances other benefits of this category yielded by T1, bringing it on par with those offered by T2 and much lower than those offered by T3 (Fig. 6). While T1 remains the most all-inclusive solution, it becomes apparent that for the financially conservative dominated sample (low input, low risk) investing in this technology does not seem optimal. Since full costs for adopting T1 have to be borne in advance, the dynamics and uncertainty about the remaining soil resilience to mismanagement interact to generate an "option value" associated with postponing T1 (Ghadim and Pannell, 1999). On the other hand, T3 scores higher in the production and socio-economic criteria domain (Fig. 6).

Regarding the three other criteria categories, T1 still yields the highest impact in terms of significant criteria for socio-cultural, ecological, and off-site benefits (Table 4). It is also notable that stakeholders value food security and water quality most, while the least valued criteria are pest species, soil

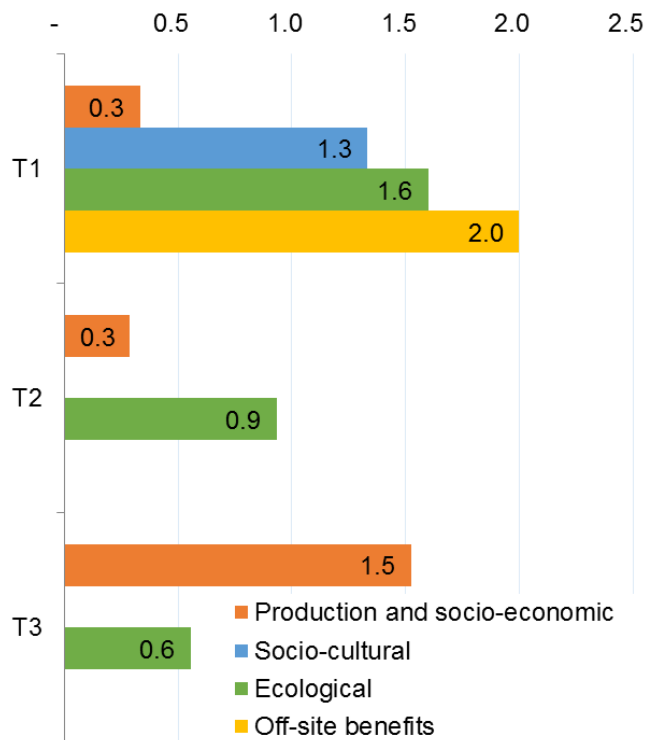

Figure 6. Cumulative score (S_c) per benefit category for the three technologies assessed.

biodiversity, and soil moisture, as greenhouse practices usually keep these factors under close control. Stakeholder preference for food security over conflict mitigation suggests a fragmented society with little coordination and low capacity of adaptation, which is not typical for rural Greece. Nevertheless, stakeholders are the least interested in reducing workload, suggesting a high level of diligence and commitment.

5 Conclusions

The variety and multidisciplinary of the stakeholders participating in the workshop allowed for an in-depth discussion on the three most promising technologies proposed by stakeholders and a comparative analysis driven by the WOCAT QT process. Using a participatory approach and the impact criteria from QT (advantages and disadvantages), the impacts of each technology on the ecosystem and human well-being were identified and evaluated (Table 4). WOCAT effectively documented SLM technology strengths and weaknesses according to expert and stakeholder opinion, along with proposed steps for sustaining and enhancing merits or mitigating inefficiencies. Based on the results of this application and the feedback of participants, the methodology facilitates effective multi-stakeholder learning processes (especially in the case of T2) that contribute to more sustainable management of land.

In the Timpaki case study it is obvious that stakeholders have a preference towards technologies that promote existing cultivations, rather than more salt-tolerant crops or alternative land use, signifying the lifelong commitment to the land and their products. To underline the existence of expertise, there are indeed examples where the joint effort of technicians and farmers with adequate investment funds has succeeded with exceptional results. Discussions revealed that certain farmers are well aware of SLM practices and are open to sharing their know-how. Nevertheless, the majority is forced to make short-term plans and focus on short-term profit maximisation due to financial circumstances and other externalities. To some extent, the three documented technologies promote sustainable agriculture management (soil protection and conservation) and reduce production failure risk and soil salinity. Even though a direct comparison is challenging, WOCAT has enabled researchers and users to rank technology impacts during the joint workshop. Results showed that T2 and T3 have a relatively low recurrent cost and almost direct return but do not present a direct solution to the soil salinity threat. As a consequence, their applicability and effectiveness may gradually decline as soil salinity increases. On the other hand T1 provides a long-term solution that enables the use of additional technologies and generates returns beyond the annual production. Above soil sustainability, the wide implementation of rainwater harvesting is bound to greatly reduce water use conflicts, thus contributing to the general well-being of the local community.

The negligible spontaneous trend towards adoption of T1 can be largely attributed to the high establishment cost and the negligible impact of agricultural input reduction compared to T2 and T3 (i.e. financial returns may not be immediately apparent). Results support the hypothesis that stakeholders tend to embrace agronomic and management measures, non-capital intensive actions, and possibly ephemeral approaches against the soil salinisation threat. This can be partly explained by a preference to adapt rather than mitigate and to offset costs of an otherwise uncertain outcome. Findings also have to be interpreted in the context of the current socio-economic conditions that have augmented financial uncertainty. Recent research by Micha et al. (2015) has highlighted the role of the financial crisis along with a range of social factors in decision making of Greek farmers.

Even though word of mouth conveys the successful results, users are willing to adopt the technology only if external material support is provided. Insight attained during the workshop points to a pattern of technology adoption where a “pioneer” applied a technology first, but the majority of users will follow only when they have run out of well-established options. Another explanation is that, for more permanent and costly solutions, stakeholders tend to anticipate structural and policy solutions to be implemented by the central government. This often means that the system is already on the verge of collapse. Possible solutions to meet this challenge half-way may be for local government to provide incentives

(i.e. to subsidise the technology) or to make it an obligatory requirement for greenhouse operation.

Acknowledgements. The research leading to these results has received funding from the European Union Seventh Framework Programme (FP7/2007–2013) under grant agreement no. 603498 (RECARE). The authors would also like to acknowledge the valuable suggestions and contribution of Konstantinos Nikoloudis and Evangelos Gibragakis.
