A small series of 5-(hetero)aryl-modified nucleoside phosphonates was synthesized via an 8-step procedure including a Wittig reaction and Suzuki–Miyaura coupling. An unanticipated anomerization during phosphonate deprotection allowed us to isolate both anomers of the 5-substituted 2′-deoxy-uridine phosphonates and assess their antiviral activity against a broad panel of viruses.

INTRODUCTION

Antiviral drugs have become crucial in the management of several viral infections, including human HSV, HIV, HBV, HCV, and cytomegalovirus (HCMV) infections. Prominent among these drugs are nucleoside analogues, which can act as potent antiviral agents owing to their ability to inhibit viral polymerases. Many publications have discussed the synthesis and antiviral activity of 5-modified 2′-deoxyuridine analogues. Several substituents have been introduced at C-5, including alkoxyethyl groups, azoles, and alkoxyoximes. Several analogues proved moderately to highly...
active against HSV. These results showed that modification at position 5 of 2'-deoxyuridine represents an interesting approach in the search for new antiviral agents. However, relatively few examples of 5-(hetero)aryl-modified nucleosides with promising antiviral activity have been reported.[4] This may be due to the fact that these nucleosides are not efficiently converted into their triphosphate form. The first step in this process, the phosphorylation of the nucleoside analogue into its 5'-monophosphate counterpart by nucleoside kinases, is often rate-limiting in the conversion to the active metabolite. One way to overcome this bottleneck is to devise prodrugs that are capable of delivering the nucleoside monophosphate intracellularly.[5,6] Another approach to bypass the first phosphorylation step is to use phosphonate analogues that, after intracellular conversion into their corresponding diphosphophosphonate forms, can exhibit antiviral activities. This led us to investigate a small series of 2'-deoxyuridine analogues that combine different aromatic substituents at position 5 of the base with a 5'-methylene phosphonate group (Figure 1).

**RESULTS AND DISCUSSION**

The synthesis of a series of 5-(hetero)aryl-modified nucleoside phosphonates started from 3'-O-tert-butyldimethylsilyl-2'-deoxy-β-D-uridine[7] and is depicted in Scheme 1. Conversion of nucleoside 6 to the vinylic phosphonate 7 was accomplished following the two-step procedure described by Cosyn et al.[8] Catalytic hydrogenation of 7 in the presence of Pd/C afforded phosphonate 8, which was selectively brominated at C-5 of the pyrimidine moiety using N-bromosuccinimide in DMF.[9] Palladium-catalyzed cross-coupling with four commercial aryl and heteroaryl boronic acids gave access to 10–13.[10] After removing the silyl protecting group, deprotection of the phosphonate esters was performed using TMSBr in CH₂Cl₂. Concomitant anomerization during this last step resulted for each analogue in a 2:1 mixture of the α- and β-isomer that could be separated using RP-HPLC.
Scheme 1 Synthesis of 5-modified 2′-deoxyuridine phosphonate analogues. Reagents and conditions: (a) 2′-Iodoxybenzoic acid, CH₃CN, 80°C, 6 hours; (ii) [(diethoxyphosphinyl)methyl]triphenylphosphorane, DMSO, rt, 20 hours, 41% over 2 steps; (b) H₂, Pd/C, MeOH, rt, overnight, 97%; (c) NBS, DMF, rt, overnight, 49%; (d) R-B(OH)₂, Na₂CO₃, Pd(PPh₃)₄, DMF, H₂O, reflux, 4 hours, 75–91%; (e) 1M TBAF in THF, rt, 1 hour, 32–71%; (f) TMSBr, CH₂Cl₂, rt, overnight, 4–19%.

Stereochemical assignment of compound 1a was based on the results of a ROESY experiment (Figure 2). A clear rOe contact between H-4′ and H-2′b (proton down) and a much weaker interaction between H-6 and H-2′b proved that H-4′ and H-6 were not positioned at the same side of the furanose ring. The β-configuration of the nucleobase was further established by the presence of a strong interaction between H-6 and H-5′a,b.
In an effort to synthesize the nonmodified 2'-deoxyuridine-5'-phosphonate analogue, compound 8 was successively treated with a 1M TBAF solution in THF and TMSBr in CH₂Cl₂ (Scheme 2). In this case, attempts to separate the anomeric mixture using flash chromatography and RP-HPLC were unsuccessful. To avoid the anomerization issue, we attempted to deprotect 18 in the presence of TMSBr under different reaction conditions. Following the reaction via \(^{31}\)P NMR, it was observed that anomerization started immediately after addition of TMSBr. We learned by attempts at different temperatures that no reaction occurred under \(-20^\circ\text{C}\) and that anomerization started simultaneously with the phosphonate hydrolysis, even at low temperature. Also, the addition of an acid scavenger (e.g., (trimethylsilyl)acetamide or 2,6-lutidine) could not prevent anomerization.\(^{[11]}\)
All compounds were evaluated for their antiviral activity against a broad panel of viruses, including HSV-1 (KOS), HSV-2 (G), vaccinia virus (VV), vesicular stomatitis virus (VSV), thymidine kinase deficient HSV-1 TK\(^{-}\) (KOS ACV\(^{+}\)), HCMV, and VZV in HEL (human embryonic lung) cell cultures; and HIV-1 (III\(B\)) and HIV-2 (ROD) in human T-lymphocyte (CEM) cell cultures. The activities of the compounds were compared with reference antiviral drugs: brivudin, cidofovir, acyclovir and ganciclovir.

None of the tested compounds showed toxicity to any of the tested cell lines. However, the final compounds 1a–4a and 1b–4b failed to show antiviral activity against HSV-1, HSV-2, VV, VSV, HSV-1 TK\(^{-}\) and different VZV strains. Also, in the human T-lymphocyte (CEM) cell cultures, none of these compounds showed activity against HIV-1 or HIV-2. Very weak antiviral activity was observed for the \(\beta\)-analogue 3a and the \(\alpha\)-analogue 2b against HCMV Davies and HCMV AD-169, respectively, whereas compounds 2a and 4a showed weak activity against both HCMV strains (Table 1). The most active compound of this series, analogue 2a, was at least 6 or 50 times less active than ganciclovir and cidofovir, respectively. The lack of biological activity of these derivatives might be attributed to several features, including 1) their inability to diffuse through the cell membrane; 2) their ineffective conversion to the corresponding diphosphophosphonate analogue; or 3) their weak affinity for the target polymerases and/or lack of incorporation into viral RNA. If uptake into the cell would be the bottleneck, converting the phosphonates to an appropriate prodrug form could be considered.

**CONCLUSION**

In conclusion, this study described the synthesis, structural analysis, and antiviral activity of a small series of 2'-deoxyuridine analogues that combine different aromatic substituents at position 5 of the base and a 5'-methylene...

phosphonate modification at the sugar moiety. All compounds were synthesized via an 8-step procedure, featuring a Wittig reaction and Suzuki–Miyaura coupling. An unexpected anomerization during the last step of the synthesis allowed us to investigate the β- as well as the α-anomers of the corresponding phosphonates. None of these analogues exhibited significant antiviral activity.

**EXPERIMENTAL**

**General Synthesis**

All reagents were from standard commercial sources and of analytical grade. Precoated Merck silica gel F254 plates were purchased for TLC; spots were examined under ultraviolet light at 254 nm and further visualized by sulfuric acid-anisaldehyde spray. Column chromatography was performed on silica gel (63–200 µm, 60 Å, Biosolve, Valkenswaard, Netherlands). With the exception of the ¹³C NMR spectrum of compound 1a, which was recorded on a 500 MHz Bruker DRX apparatus, all NMR spectra were determined using a Varian Mercury 300 MHz spectrometer. Chemical shifts are given in ppm (δ) relative to the residual solvent signals, which in the case of DMSO-d₆ were 2.54 ppm for ¹H and 40.5 ppm for ¹³C. Structural assignment was confirmed with COSY and DEPT. All signals assigned to hydroxyl groups were exchangeable with D₂O. Exact mass measurements were performed on a Waters LCT Premier XETM time of flight (TOF) mass spectrometer.
equipped with a standard electrospray ionization (ESI) and modular Lock-Spray TM interface (Waters Corp., Milford, MA, USA). Samples were infused in a CH$_3$CN/water (1:1) mixture at 10 µL/min.

1-[3-O-tert-Butyldimethylsilyl-2,5,6-trideoxy-6-(diethoxyphosphinyl)-β-D-hex-5-enofuranosyl]-uracil (7)

2′-Iodoxybenzoic acid (550 mg, 1.97 mmol) was added to a solution of 6 (449 mg, 1.31 mmol) in CH$_3$CN (12 mL) and the resulting suspension was stirred at 80°C for 6 hours. After cooling in an ice bath (15 minutes), the solid was removed by filtration and washed with cold CH$_3$CN. The solvent was evaporated and the residue was co-distilled with toluene. The combined organic layers were dried over MgSO$_4$, filtered, and concentrated in vacuo. The residue was lyophilized to remove the remaining DMSO and purified on a silica gel column (CH$_2$Cl$_2$/MeOH 98:2) yielding 257 mg (41%) of 7 as a colourless solid. $^1$H NMR (300 MHz, DMSO-d$_6$): $\delta$ 0.070 (6H, s, TBDMS), 0.87 (9H, s, TBDMS), 1.23 (6H, app dt, $J = 1.5$ Hz, $J = 6.9$ Hz, 2 x OCH$_2$CH$_3$), 2.13–2.22 (1H, m, H-2′a), 2.34–2.43 (1H, m, H-2′b), 3.92–4.03 (4H, m, 2 x OCH$_2$CH$_3$), 4.20–4.25 (1H, m, H-4′), 4.38–4.45 (1H, m, H-3′), 5.64 (1H, d, $J = 7.8$ Hz, CH=CH), 5.96–6.09 (1H, m, H-6′), 6.16 (1H, dd, $J = 6.0$ Hz, $J = 7.5$ Hz, H-1′), 6.60–6.75 (1H, m, H-5′), 7.68 (1H, d, $J = 8.4$ Hz, CH=CH), 11.34 (1H, s, 3-NH). $^{31}$P NMR (DMSO-d$_6$): $\delta$ 17.21. $^{13}$C NMR (75 MHz, DMSO-d$_6$): $\delta$ -5.02, -4.87 (TBDMS), 16.10, 16.18 (OCH$_2$CH$_3$), 17.60 (TBDMS), 25.57 (TBDMS), 61.21, 61.31 (OCH$_2$CH$_3$), 74.36 (C-3′), 84.27 (C-1′), 85.27 (C-4′, d, $J = 23$ Hz), 102.07 (C-5), 119.70 (C-6′, d, $J = 182$ Hz), 141.38 (C-6), 147.81 (C-5′, d, $J = 5$ Hz), 150.29 (C-2), 162.98 (C-4). General Procedure for the Synthesis of 5-Modified Nucleoside Phosphonates via Suzuki-Miyaura Coupling

A mixture of compound 9 (1 equiv.), aryl boronic acid (2 equiv.), Pd(PPh3)4 (0.1 equiv.) and Na2CO3 (3.3 equiv.) in DMF and degassed H2O was heated (± 130°C, oil bath) under argon for 6 hours or until TLC indicated consumption of all starting material. The mixture was then concentrated and co-distilled with toluene. The residue was purified by column chromatography (CH2Cl2/MeOH 94:6–98:2), affording the 5-modified analogues in moderate yield.

1-[3-O-tert-Butyldimethylsilyl-2,5,6-trideoxy-6-(diethoxyphosphinyl)-β-D-hexofuranosyl]-5-phenyluracil (10)

Reaction of compound 9 (153 mg, 0.27 mmol) with phenylboronic acid (68 mg, 0.55 mmol), Pd(PPh3)4 (32 mg, 0.027 mmol) and Na2CO3 (96 mg, 0.91 mmol) in DMF (6.5 mL) and degassed H2O (0.8 mL) was performed as described in the general procedure to yield compound 10 as a colorless solid (120 mg, 79%). 1H NMR (300 MHz, CDCl3): δ 0.084 (6H, s, TBDMS), 0.90 (9H, s, TBDMS), 1.25–1.32 (6H,

General Procedure for the Deprotection of 5-Modified Nucleoside Phosphonates

The phosphonic ester (1 equiv.) was dissolved in CH$_2$Cl$_2$ under argon. TMSBr (2 equiv.) was added and the resulting solution was stirred overnight. The solvent was evaporated and the residue dissolved in a mixture of EtOAc/Et$_2$O (1:1) and water. The organic phase was washed with water and the water layers were combined and lyophilized. Purification of the crude using RP-HPLC (Phenomenex Luna C-18, H$_2$O/0.1% HCOOH in CH$_3$CN, 90:10 → 0:100 in 23 minutes, flow 17.5 mL/minute) afforded 2 series of compounds: the α- (retention time ≥ 12 minutes) and β-isomer (retention time ≈ 10–11 minutes) of each phosphonate.

1-[2,5,6-Trideoxy-6-(diethoxyphosphinyl)-β-D-hexofuranosyl]-uracil (18)

Compound 8 (309 mg, 0.65 mmol) was dissolved in 4.1 mL THF and a TBAF solution in THF (1M, 1.44 mL, 1.44 mmol) was added at rt. After stirring for 3 hours the reaction mixture was evaporated in vacuo and poured on a silica column (CH$_2$Cl$_2$/MeOH 92:8) to give compound 18 (162 mg, 69%) as a colorless solid. $^1$H NMR (300 MHz, DMSO-d$_6$): δ 1.23 (6H, t,

Experimental Assay

**Antiviral and Cytotoxicity Assays for Compounds 1a–4b**

The antiviral activity of the new compounds was determined using a cytopathogenicity assay against herpes simplex virus type 1 (HSV-1) (KOS...

strain), herpes simplex virus type 2 (HSV-2) (G strain), vaccinia virus, vesicular stomatitis virus, HSV-1 TK− KOS ACV in HEL cell cultures. Stock solutions of the test compounds were prepared in DMSO at a concentration of 10 mg/mL. Cells, grown to confluency in 96-well plates, were infected with 100 CCID₅₀ of virus, one CCID₅₀ being the 50% cell culture infective dose in the presence of varying concentrations of the test compounds. Cultures were further incubated until complete cytopathogenicity was observed in the infected and untreated virus control. The cytotoxicity of the compounds was evaluated in parallel with their antiviral activity in uninfected cells and is expressed as the minimum cytotoxic concentration (MCC) that causes a microscopically detectable alteration of normal cell morphology. The symbol “>” is used to indicate the highest concentration at which the compounds were tested and found not to be antivirally active.

For the anti-HCMV and anti-VZV assays, HEL fibroblasts were infected with 100 PFU per well. Compounds were added after a 1 hour-incubation period, and the cells were further incubated at 37°C. After 5 (VZV) and 7 days (HCMV) of incubation, plaques (VZV) or virus-induced cytopathogenicity (HCMV) was monitored microscopically after ethanol fixation and staining with Giemsa solution. The cytotoxicity of the compounds was evaluated in parallel with their antiviral activity in uninfected cells and is expressed as the minimum cytotoxic concentration that causes a microscopically detectable alteration of cell morphology (MCC) and the concentration required to reduce cell growth by 50% (CC₅₀).

Determination of the anti-HIV activity of the compounds was based on virus-induced cytopathogenicity of HIV-infected CEM cells, measured at day 4 to 5 postvirus infection by microscopically estimating virus-induced syncytia formation. The cytostatic activity of the compounds was evaluated in parallel with their antiviral activity in uninfected cell cultures and is expressed as the 50%-inhibitory concentration for the proliferation of the T-lymphocyte CEM cells (EC₅₀).
