OBJECTIVE
The aim of the study was to trace the correlation between dynamic balance and gait parameters during the application of specialized kinesitherapeutic methodology (SKTM) in patients with ischemic stroke in the chronic period (ISChP)

MATERIALS AND METHODS
The study was conducted with 56 patients with ISChP. The Berg Balance Scale is used for the evaluation of the balance reactions. Tracking changes in gait before and after the applied treatment is evaluated cadence of gait and maximum speed of movement. To determine the cadence, the number of steps is measured for covering 6 meters and 10 meters. The maximum speed of the gait is determined in m / min by dividing undergone distance (m) / time (min), for which they have walked it. All indicators were assessed at the baseline, on the 10th day, 1st month and 3rd months after the beginning of the kinesitherapy. The patients studied were treated with a specialized 10-day kinesitherapy, which later continues to be performed by patients as an adapted exercise program at home for a period of three months.

RESULTS
After applying SKTM, the highest tendency towards improvement in dynamic balance and gait is established in the 1st month, with a level of significance p=0.000. The correlations between the studied parameters were most visible on the 10th day after the start of the applied SKTM with a significance level of p<0.01.

CONCLUSIONS
The applied specialized kinesitherapeutic methodology continued later as an adapted exercise program at home, significantly improving the dynamic balance and gait parameters in patients with functional impairment due to ISChP.
