THIS PAGE INTENTIONALLY LEFT BLANK
The absence of common software platforms for Autonomous Underwater Vehicle (AUV) mission planning and analysis is an ongoing impediment to collaborative work between research institutions, their partners, and end users. This thesis details the design and implementation of a distributable application to facilitate AUV mission planning and analysis. Java-based open-source libraries and a component-based framework provide diverse functionalities. The extensible Markup Language (XML) is used for data storage and message exchange, Extensible 3D (X3D) Graphics for visualization and XML Schema-based Binary Compression (XSBC) for data compression. The AUV Workbench provides an intuitive cross-platform-capable tool with extensibility to provide for future enhancements such as agent-based control, asynchronous reporting and communication, loss-free message compression and built-in support for mission data archiving. Exemplars show that the XML backbone of this open-source technology can be leveraged to enable both human and agent messaging with improvements over current systems. Integrated Jabber instant messaging support makes the NPS AUV Workbench the first custom application supporting XML Tactical Chat (XTC).

Results demonstrate that the AUV Workbench provides a capable test bed for diverse AUV technologies, assisting in the development of traditional single-vehicle operations and agent-based multiple-vehicle methodologies. The flexible design of the Workbench further encourages integration of new extensions to serve operational needs. Exemplars demonstrate how in-mission and post-mission event monitoring by human operators can be achieved via simple web page, standard clients or custom instant messaging client. Finally, the AUV Workbench’s potential as a tool in the development of multiple-AUV tactics and doctrine is discussed.
NPS AUV WORKBENCH: COLLABORATIVE ENVIRONMENT FOR AUTONOMOUS UNDERWATER VESICLES (AUV) MISSION PLANNING AND 3D VISUALIZATION

ABSTRACT

The absence of common software platforms for Autonomous Underwater Vehicle (AUV) mission planning and analysis is an ongoing impediment to collaborative work between research institutions, their partners, and end users. This thesis details the design and implementation of a distributable application to facilitate AUV mission planning and analysis. Java-based open-source libraries and a component-based framework provide diverse functionalities. The extensible Markup Language (XML) is used for data storage and message exchange, Extensible 3D (X3D) Graphics for visualization and XML Schema-based Binary Compression (XSBC) for data compression. The AUV Workbench provides an intuitive cross-platform-capable tool with extensibility to provide for future enhancements such as agent-based control, asynchronous reporting and communication, loss-free message compression and built-in support for mission data archiving.

This thesis also investigates the Jabber instant messaging protocol, showing its suitability for text and file messaging in a tactical environment. Exemplars show that the XML backbone of this open-source technology can be leveraged to enable both human and agent messaging with improvements over current systems. Integrated Jabber instant messaging support makes the NPS AUV Workbench the first custom application supporting XML Tactical Chat (XTC).

Results demonstrate that the AUV Workbench provides a capable testbed for diverse AUV technologies, assisting in the development of traditional single-vehicle operations and agent-based multiple-vehicle methodologies. The flexible design of the Workbench further encourages integration of new extensions to serve operational needs. Exemplars demonstrate how in-mission and post-mission event monitoring by human operators can be achieved via simple web page, standard clients or custom instant messaging client. Finally, the AUV Workbench’s potential as a tool in the development of multiple-AUV tactics and doctrine is discussed.

ACKNOWLEDGMENTS

I would like to thank Don Brutzman for his ideas, in-depth knowledge in the area of XML, AUV modeling and simulation and opportunities, Curt Blais for his guidance on agent technology and XML, John Hiles for introducing the concepts of cognitive blending and LCDR Duane Davis for being a great sounding board and his in-depth domain knowledge, and most importantly, my patient and loving wife, Joanne who has been a great source of strength all through this work. Not forgetting our families back home in Singapore.
I. INTRODUCTION

A. PROBLEM STATEMENT

The lack of common software tools for Autonomous Underwater Vehicle (AUV) mission planning and analysis is an ongoing impediment to collaborative work between research institutions, their partners, and end users. Current proprietary software solutions have a myopic view on the capability of AUVs. Most place too much emphasis on single and relatively simple AUV operations. A common software development and mission evaluation platform will not only facilitate modeling and simulation of AUVs, but it will aid in the introduction of complex multi-agent systems to try out and answer more challenging questions. Longer-term needs such as the development of AUV concept of operations and collaborative sensing between vehicles can be achieved.

A common and flexible platform will facilitate the transition from simulation to actual operations.

B. OVERVIEW

This thesis details the design and implementation of a common platform to facilitate AUV mission planning, visualization and analysis. The end product is capable of handling the various phases of a mission. An important component is the definition and use of a common AUV mission control script. The control script defines the AUV commands that are similar to the low-level execution commands that are used by the actual AUV hardware.

Using Java-based open-source libraries for functionality, Extensible Markup Language (XML) for data storage [Serin 2003] and exchange, and a component-based framework, the AUV Workbench provides an intuitive cross-platform-capable tool with extensibility to provide for future enhancements such as agent-based control, asynchronous reporting and communication, and loss-free message compression. As a collaboration environment, it is important that communication channels and tools are
easily available for developers and users to communicate. Jabber instant messaging is selected as it is based on open-source Extensible Message and Presence Protocol (XMPP) [XMPP 2004].

In addition, this thesis investigates the Jabber instant messaging protocol and discusses its suitability for text and file messaging in a tactical environment. Exemplars show that the XML backbone of this open-source technology can be leveraged to enable both human and agent messaging with improvements over current systems.

C. MOTIVATION

One motivating factor is to support the current research efforts at NPS and with partners such as Singapore Defence Science Organization (DSO). Similar partner relationships are occurring with other AUV laboratories. A componentized framework using open-source software and open-standards technologies is presented to support collaborative development. The ultimate goal of software components is to fuse the use of different pieces of software into one smoothly operating package. The end product facilitates collaboration and continued research development between the two research entities.

A well-designed and well-documented system promotes knowledge sharing and retention. Ease of use and user interface design is important issues that will determine whether it gains user acceptance. Usability should not be considered as an afterthought. Ultimately user acceptance aids the transition of a modeling and simulation (M&S) tool into a system that meets operational needs.

A further long-term motivation is to develop a common platform that can be extended to become a Sensor Workbench and also support agent research and development. Much important work awaits; that is otherwise impossible without such a dedicated tool. In many respects, the NPS AUV Workbench is the culmination of many technical threads carrying to fruition that were first initiated as part of the NPS AUV Underwater Virtual World. [Brutzman 1994]
D. OBJECTIVES

The primary focus of this thesis is on the design and implementation of a common platform for AUV mission planning and analysis through the use of Open-source software and tools. In addition, this thesis addresses the following research questions:

- What are the open-source tools and open-standards technologies available to facilitate development of a collaborative platform for AUV mission planning and visualization?
- What constitutes an AUV XML-based mission control script?
- Can the mission control script be graphically represented?
- How can open-standards technologies be leveraged to design and implement a message exchange system that can support both human and machine communications?
- Can Jabber be used for machine-to-machine communications; e.g., for self-validating agent-to-agent messaging?
- Can binary files be transported via Jabber instant messaging protocol?
- Can Jabber instant messaging together with HTTP, serve as a reliable means for the transfer of textual and binary data?

E. THESIS ORGANIZATION

This first chapter identifies the purpose and motivation behind conducting this research and establishes the goals for the thesis. Chapter II discusses similar research and provides general background information to the concepts and set of tools and technologies employed in this thesis. Chapter III examines the design and implementation of the various modules that make up the AUV Workbench application. Chapter IV discusses the use of Jabber instant messaging protocol for message exchange of textual and files. It provides an exemplar on how event monitoring can be implemented. Chapter V analyzes the software design of AUV agents. Chapter VI gives a summary of the conclusions and recommendations for future work. The future work section lists eleven specific areas where this thesis can be extended. The appendices
present information on the programming source code produced and system installation in conjunction with this thesis. All source code and model content are provided online and in Appendix C.
II. BACKGROUND AND RELATED WORK

A. INTRODUCTION

This chapter briefly discusses the technologies and tools leveraged in the conduct of this thesis. An overview on the open-source tools and open-standards technologies employed is given. This chapter also summarizes pertinent previous work on the current NPS AUV and its virtual world software. Further explanation and study of the topics may be found in the list of references at the end of this thesis.

B. DATA REPRESENTATION AND MANIPULATION USING XML

Data is only as good as the way it is packaged. Information is a valuable asset, but its value depends on its longevity, flexibility, and accessibility. Traditionally, data is represented in a simple text-based format (see Table 1). The main disadvantage of such an approach is that it is likely to introduce ambiguity in how the data is captured, resulting in additional effort to write a robust parser to handle the ambiguity. This parser has to handle case-sensitivity (“WAYPOINT” is not the same as “Waypoint”) and potential variations in user input (e.g., “WAYPOINT” and “WAYPOINT-ON” refer to the same information). This added logic slows down (and may confuse) in-water processing time.

| WAYPOINT    #X #Y [#Z] [#rpm] |
| WAYPOINT-ON #X #Y [#Z] [#rpm] |
| Point towards waypoint with coordinates (#X, #Y) (depth #Z optional) (speed #rpm optional). You can leave waypoint control by ordering course, rudder, sliding-mode, rotate or lateral thruster control. |
| If speed is < 200 RPM, port & starboard RPMs are increased to 400 RPM to ensure waypoint can be achieved. |
| If in TACTICAL mode, execution reports STABLE when waypoint is achieved. |

Table 1. Description of text-based command for Waypoint orders. Extracted from mission.script.HELP [Brutzman 1994].
The World Wide Web Consortium’s (W3C’s) XML Working Group developed Extensible Markup Language (XML) in 1996. XML evolved out of the earlier Standard Generalized Markup Language (SGML), HyperText Markup Language (HTML), and the earliest presentation markup language. XML documents contain only data, not formatting instructions. XML is an open standard and its extensibility allows it to markup virtually any type of information. XML is a simple, standard way to interchange structured textual data between applications. It is also readable and writable by humans, using a simple text editor.

Some examples of XML languages are Extensible HyperText Markup Language (XHTML), Sensor Markup Language (SensorML) for sensors [SensorML], Defense Advanced Research Projects Agency (DARPA) Agent Markup Language (DAML) for agents [DAML], Geography Markup Language to describe geographic information [GeoML], MathML for mathematics [MathML], and Chemical Markup Language (CML) [CML]. A list of XML-based data representation can be found at http://www.xml-acronym-demystifier.org/xmlad.html (Accessed February 2004). The design goals for XML are shown in Table 2 below.

<table>
<thead>
<tr>
<th>Point</th>
<th>Goal</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>XML shall be straightforwardly usable over the Internet.</td>
</tr>
<tr>
<td>2.</td>
<td>XML shall support a wide variety of applications.</td>
</tr>
<tr>
<td>3.</td>
<td>XML shall be compatible with SGML.</td>
</tr>
<tr>
<td>4.</td>
<td>It shall be easy to write programs that process XML documents.</td>
</tr>
<tr>
<td>5.</td>
<td>The number of optional features in XML is to be kept to the absolute minimum, ideally zero.</td>
</tr>
<tr>
<td>6.</td>
<td>XML documents should be humanly legible and reasonably clear.</td>
</tr>
<tr>
<td>7.</td>
<td>The XML design should be prepared quickly.</td>
</tr>
<tr>
<td>8.</td>
<td>The design of XML shall be formal and concise.</td>
</tr>
<tr>
<td>9.</td>
<td>XML documents shall be easy to create.</td>
</tr>
<tr>
<td>10.</td>
<td>Terseness in XML markup is of minimal importance.</td>
</tr>
</tbody>
</table>

Table 2. XML Design Goals (after W3C, 2003).

1. **Removing Ambiguity Through Namespaces**

Namespace is a mechanism by which element and attribute names can be assigned to groups. They provide means for document authors to prevent ambiguity and are most often used when combining different vocabularies in the same document. Namespace
identifiers have to be assigned some kind of unique identifiers. They are, by convention, assigned to the Uniform Resource Locator (URL) subset of Uniform Resource Identifiers (URIs), not the more abstract Uniform Resource Names (URNs). However, this is not a requirement, since the XML parser does not actually look up any information located at that URL.

2. Defining the XML Document Structure

An XML document can optionally reference a document that defines the document structure and data type. This document can either be represented as Document Type Definition (DTD) or a schema. DTDs were originally developed for XML’s predecessor, SGML. They use a compact syntax and provide document-oriented data typing. XML DTDs are a subset of those available in SGML, and the rules for using XML DTDs provide much of the complexity of XML 1.0.

XML Schema is an XML-based alternative to DTD. The XML Schema language is also referred to as XML Schema Definition (XSD). XSD expresses shared vocabularies and allows machines to carry out rules made by people. It provides a means for defining the structure, content and semantics of XML documents [Schema 2004].

Through the use of a schema or DTD, the XML document can be validated (i.e., checked for conformity) as it is parsed. If the XML document follows the DTD or schema, it is valid. If an XML parser can successfully parse an XML document, it means that the document is syntactically correct (well-formed). Therefore a valid XML document is also well-formed.

DTDs are not XML documents (See Figure 1). This makes them difficult to programmatically manipulate. A DTD describes an XML document’s structure but not the format of the individual elements. In 1999, the W3C began to develop XML Schemas in response to the growing need for a more advanced format for describing XML documents. XML Schemas reached recommendation status in May 2001.

Table 3. Comparison of DTD and XSD.
3. Transforming XML Documents

As the name implies, Extensible Stylesheet Language (XSL) is intended to define the formatting and presentation of XML documents for display. The first proposal for XSL was dated 21 August 1997 [XSL 2004].

XSL Transformations (XSLT) is a language designed for transforming XML documents into other XML documents [XSL 2004]. Just as XML was derived from SGML, XSLT has its origins in an SGML-based standard, Document Style Semantics and Specification Language (DSSSL). A transformation expressed in XSLT describes rules for transforming a source tree into a result tree. The transformation is achieved by associating patterns with templates. A pattern is matched against elements in the source tree. A template is instantiated to create part of the result tree. The result tree is separate from the source tree. The structure of the result tree can be completely different from the structure of the source tree. In constructing the result tree, elements from the source tree can be filtered and reordered, and arbitrary structure can be added. A transformation expressed in XSLT is called a stylesheet.

XSLT is designed for use as part of XSL, which is a stylesheet language for XML. XSL specifies the styling of an XML document by using XSLT to describe how the document is transformed into another XML document that uses the formatting vocabulary. XSLT is designed to work independently of XSL. The dominant feature of XSLT is that it is declarative. It produces an output when a particular pattern (based on a set of non-sequential template rules) occurs in the input. This is opposed to a procedural program where the tasks are defined in the order they are supposed to perform. Apache Xalan is a Java-based open-source XSLT processor [Xalan 2004] that is used in this thesis.

The basic relationship between an XML document with XSL and XSD is illustrated in Figure 3.
Figure 3. Relationship of Parsing, Validating and Transforming an XML document.

C. 2D AND 3D GRAPHICS REPRESENTATION

1. Scalable Vector Graphics (SVG)

SVG is a language for describing two-dimensional graphics and graphical applications in XML. It was created by the World Wide Web Consortium (W3C), the non-profit, industry-wide, open-standards consortium that created HTML and XML, among other important standards and vocabularies. SVG allows for three types of graphic objects: vector graphic shapes (e.g., paths consisting of straight lines and curves), images and text. Graphical objects can be grouped, styled, transformed and composited into previously rendered objects. Text can be in any XML namespace suitable to the application, which enhances searchability and accessibility of the SVG graphics. The feature set includes nested transformations, clipping paths, alpha masks, filter effects, template objects and extensibility. As an XML grammar, SVG offers all the advantages of XML. SVG graphics can easily be generated on Web servers "on the fly," using standard XML tools, many of which are written in the Java programming language [SVG 2004].
SVG drawings are dynamic and interactive. The Document Object Model (DOM) for SVG, which includes the full XML DOM, allows for straightforward and efficient vector graphics animation via scripting. A rich set of event handlers such as onmouseover and onclick can be assigned to any SVG graphical object. Because of its compatibility and leveraging of other Web standards, features like scripting can be done on SVG elements and other XML elements from different namespaces simultaneously within the same Web page.

SVG 1.1 is a W3C Recommendation and forms the core of the current SVG developments. SVG 1.2 is the specification currently being developed.

```xml
<svg width="360" height="120">
  <rect x="0" y="0" width="100%" height="100%" fill="lightgray"/>
  <g id="sampleLogo" transform="translate(5, 5)">
    <rect fill="#ff3366" width="155" height="70"/>
    <image xlink:href="sample.svg" x="15" y="15" width="120" height="40"/>
  </g>
  <rect fill="#3366ff" x="165" y="5" width="180" height="70"/>
  <rect fill="#FFFF00" x="10" y="80" width="335" height="35"/>
  <g font-family="SunSansCondensed-Heavy" fill="black" font-size="20" stroke="white">
    <text x="20" y="70" stroke="none" >NPS AUV Workbench</text>
  </g>
</svg>
```

Figure 4. A simple SVG code snippet.

![SVG code snippet](image)

Figure 5. Graphical representation of the above SVG code.

2. **Virtual Reality Modeling Language (VRML)**

The Virtual Reality Modeling Language (VRML) is an International Standards Organization (ISO) standard for defining 3D virtual worlds through the use of a structured text file, such as depicted in Figure 6. The text files are typically small and are ideal for transmission over the Internet. VRML files typically contain four main types of components; header, prototypes, shapes and routes. VRML virtual worlds are rendered...
using specialized viewers that read the VRML text files and render the content defined in the file, (e.g., ParallelGraphics Cortona VRML Client 4.2 at http://www.parallelgraphics.com accessed on February 2004). These viewers are installed as Internet browser plug-ins. There are also several open-source VRML viewers available on the Internet, such as Xj3D [XJ3D 2004].

```VRML
#VRML V2.0 utf8
NavigationInfo {
  type [ "EXAMINE" "ANY" ]
}
Shape {
  appearance Appearance {
    material Material {
      diffuseColor 0 0 1
    }
  }
  geometry Box {
    size 1 0.5 1
  }
}
```

Figure 6. Contents of VRML file for a 1m by 0.5m by 1m blue box.

Figure 7. Rendering of the 1m by 0.5m by 1m blue box defined in Figure 6 using Internet Explorer and the Cortona VRML plug-in. User has rotated the scene for a custom viewpoint location and orientation.
3. **Extensible 3D (X3D) Graphics**

X3D Graphics is the next generation of the Virtual Reality Markup Language 1997 (VRML97) 3D graphics format for the Internet. X3D has been developed with an open-source sample implementation for specification implementation and evaluation along with support from major industry players in 3D content development for the Internet. Since the format is XML based, it can also take advantage of the benefits of XML through the use of XSLT stylesheets to view the same content rendered in VRML97, HTML or with direct rendering of the XML-based tree structure in an open-source browser implementation such as Xj3D [XJ3D 2004].

4. **Xj3D 3D Display Library**

Xj3D is the open-source rendering implementation for the X3D graphics standard [XJ3D 2004]. It is “a Java-based toolkit developed by Yumetech that allows companies to rapidly support X3D.”[X3D 2002] The Web3D Consortium has also formed the Java Rendering Working Group consisting of members from Media Machines Inc. Anaviza Inc., Sun Microsystems, and Yumetech that are concurrently working on the definition and implementation of bindings for various common graphical API’s such as OpenGL® and Direct3D™. Upon completion, this implementation will make the specific graphics rendering context of X3D graphics agnostic and this less vulnerable to the commercial “ups and downs” of the market place or consumer popularity.

D. **JABBER AND EXTENSIBLE MESSAGING AND PRESENCE PROTOCOL (XMPP)**

Jabber is a set of streaming XML protocols and technologies that enable any two entities on the Internet to exchange messages, presence, and other structured information in close to real time. The first Jabber application is an instant messaging (IM) network that offers functionality similar to legacy IM services such as AIM, ICQ, MSN, and Yahoo. However, Jabber is more than just IM, and Jabber technologies offer several key advantages [Jabber 2004]: Jabber protocols are free, open, public, and easily
understandable; in addition, multiple implementations exist for clients, servers, components, and code libraries.

First developed by Jeremie Miller in 1998, Jabber is becoming a stable and proven piece of technology. The architecture of the Jabber network is similar to email; as a result, anyone can run their own Jabber server, enabling individuals and organizations to take control of their IM experience. Robust security using Simple Authentication and Security Layer (SASL) and Transport Layer Security (TLS) has been built into the core XMPP specifications.

Using the power of XML namespaces, it is extensible in that anyone can build custom functionality on top of the core protocols; to maintain interoperability, common extensions are managed by the Jabber Software Foundation. Jabber-enabled applications are more than IM. These include network management, content syndication, collaboration tools, file sharing, gaming, and remote systems monitoring.

With a wide range of companies and open-source projects using the Jabber protocols to build and deploy real-time applications and services; there is no technology “locked in” as compared to proprietary tools or technologies.

The Extensible Messaging and Presence Protocol (XMPP) is a general purpose protocol not necessarily limited to instant messaging and presence [XMPP 2004]. XMPP is a revision of the communication portion of the widely deployed Jabber protocol. XMPP is a TCP-based protocol that uses Extensible Markup Language (XML) as the syntax for its protocol elements. XMPP can be used as a client-to-server protocol as well as a server-to-server protocol. The base of the protocol exchange is the XML “stream”, effectively a stream of XML data sent from one party to the other which starts with an XML <stream> tag and ending with an XML </stream> tag. Streams are unidirectional, so communication between two parties requires two separate streams (though they can run over the same full-duplex connection). Within the stream, Requests and Responses are exchanged between the two parties in XML “stanzas”, a portion of the stream that has semantic content. The document describes the routing of stanzas from machine to machine through streams. XMPP includes guidelines to ensure that extensions are possible without conflicts or breaking core interoperability. Lack of conflicts is ensured
with use of XML namespaces. Interoperability is ensured with careful layering of stanzas of known types, on top of the base stream.

The Internet Engineering Task Force (IETF) has formalized the core XML streaming protocols as an approved instant messaging and presence technology under the name of XMPP, and the XMPP specifications are moving forward rapidly within the IETF’s standards process (http://www1.ietf.org/mail-archive/ietf-announce/Current/msg28170.html accessed 29 January 2004)

E. OPEN-STANDARD TECHNOLOGIES AND OPEN-SOURCE SOFTWARE

Open-source software is freely available for any use, including modification and redistribution. The first formal statement of the official Open Source definition appeared in 1997 by Bruce Perens [OSI 2002]. This definition has continued to be refined and maintained by the Open Source Initiative (OSI), a non-profit corporation. [OSI 2004] Developers have a say in how open source are designed and are free to use what works for them, rather than be tied to a particular proprietary package. The plethora of open standards and open source components has shown that this approach is a viable one.

Open source products and tools are based on the premise that the programming source code is freely available to anyone who wishes to read, add to, or even modify and redistribute the computer software code. Thus “free” refers primarily to “freedom to use and modify”.

The list of open source libraries used in the AUV Workbench application is given in Table 4.

### F. PROGRAMMING LANGUAGE AND DEVELOPMENT ENVIRONMENT

The Java Programming Language by Sun Microsystems is the primary language used for this thesis [JDK142]. With Java, numerous commercial and open-source tools, notably Jakarta Apache at [http://jakarta.apache.org](http://jakarta.apache.org) (accessed February 2004) are available.

The choice to use Borland’s JBuilder 7.0 Enterprise (NPS Education Edition) for development of the AUV Workbench was largely based on the author’s familiarity with Borland’s Integrated Development Development (IDE) from the use of Borland’s Object Pascal, Delphi. The edition of Java used is Java 2 Standard Edition (J2SE) JDK1.4.2. There is no dependency on any particular IDE for development of the NPS AUV Workbench. The NetBeans and Eclipse IDEs are both open source and good no-cost alternatives.

Most IDEs provide tools to easily design a user interface and automatically generate the interface code. This comes at the expense of over-dependence on a particular IDE and likely to pose problems when the user interface needs to be amended on another IDE. Therefore the design and implementation of the AUV Workbench graphical user interface is coded from scratch, instead of using JBuilder’s Graphical User Interface (GUI) Designer.
The following sections provide a brief description on some of the IDEs currently available, consisting of both commercial (e.g., Borland JBuilder) and open-source tools such as NetBeans and Eclipse.

1. **JBuilder**

JBuilder uses one window to perform most of the development functions: editing, visual designing, navigating, browsing, compiling, debugging, and other operations. This window is called the AppBrowser, and it contains several panes for performing these development functions. The tabbed panes that are available in the content pane depend on what kind of file is selected in the project pane.

![JBuilder 7.0 application user interface running on Windows XP platform.](image)

Figure 8. Borland JBuilder 7.0 application user interface running on Windows XP platform.
2. **Eclipse**

Eclipse is an open-source software development project dedicated to providing a robust, full-featured, commercial-quality, industry platform for the development of highly integrated tools. It is composed of three projects, the Eclipse Project, the Eclipse Tools Project and the Eclipse Technology Project (http://www.eclipse.org accessed January 2004.). It is composed of three subprojects: Platform, Java Development Tools (JDT), and Plug-in Development Environment (PDE).

The Eclipse Tools Project provides a focal point for diverse tool builders to ensure the creation of best of breed tools for the Eclipse Platform. The mission of Eclipse Tools Project is to foster the creation of a wide variety of tools for the Eclipse Platform. The Tools project provides single point of coordination for open-source tool developers in order to minimize overlap and duplication, ensure maximum sharing and creation of common components, and promote seamless interoperability between diverse types of tools.
The Eclipse Platform is an open extensible IDE. The Eclipse Platform provides building blocks and a foundation for constructing and running integrated software-development tools. The Eclipse Platform allows tool builders to independently develop tools that seamlessly integrate with other people's tools.

The Eclipse SDK (software developer kit) is the consolidation of the components produced by the three Eclipse Project subprojects (Platform, JDT - Java development tools, and PDE - Plug-in development environment) into a single download.

Figure 10. Eclipse SDK 3.0 Stream Stable Build user interface running on Windows XP platform.
Figure 11. CodeAssist feature running in Eclipse. This feature displays context-sensitive pop-up windows to facilitate code completion.

3. **NetBeans**

The NetBeans platform is an application runtime - a "generic large desktop application." NetBeans Integrated Development Environment (IDE) comprises the platform and modules such as an editor, tools for working with source code (e.g., Java and C++) and version control. The IDE has advanced syntax highlighting and an error checking code editor that supports Java, C, C++, XML and HTML languages. Some of the features of the platform are ([http://www.netbeans.org](http://www.netbeans.org) accessed January 2004):

- User interface management - Windows, menus, toolbars and other presentation components are provided by the Platform. Developers write to a set of abstractions such actions and components, saving time and producing cleaner, more bug-free code. Custom components and behaviors can be written, but for most cases this is not needed.

- Data and presentation management - The NetBeans Platform contains a rich toolset for presentating data to the user and manipulating that data.
• The Editor - Available as an extension to the Platform, applications built on NetBeans can use the NetBeans Editor, a powerful and extensible toolset for building custom editors.

• Setting management - The NetBeans Filesystems infrastructure abstracts file-based data. Files may exist locally or remotely, on FTP or CVS servers or in a database; access to them is transparent to module code that works with files. The Platform can be extended to support new forms of storage. Applications built on NetBeans are Internet-ready.

• The Wizard framework - a toolset for easily building extensible, user-friendly Wizards to guide users through more complex tasks.

• Configuration management - Rather than tediously write code to access remote data and manage and save user-configurable settings, etc., all of this is handled by the Platform. Applications consist of the platform and the logic code important to that application.

• Storage management - An abstraction of file-based data access. "Files" in the NetBeans paradigm may be local files, or exist remotely, for example, on an FTP server, CVS repository or in a database. Where this data is stored is completely transparent to other modules that work with this data.

• Cross-platform - since the Platform is written entirely in the Java language, applications based on it, by their very nature, will run on any operating system with a Java 2 compatible (1.3 or greater) JVM.

The IDE has a dynamic code completion feature for the Java Editor that enables you to type a few characters and then display a list of possible classes, methods, variables, and so on that can be used to automatically complete the expression.

G. NPS ARIES AUTONOMOUS UNDERWATER VEHICLES (AUV)

1. Introduction

The Naval Postgraduate School Center for AUV Research has been building, operating, and researching autonomous underwater vehicles (AUVs) since 1987. Each new generation of vehicles have substantially increased operational capabilities and are much more robust and sophisticated in terms of hardware and computer software. These vehicles have also moved from operating in swimming pool environments to the open ocean [Oceans 2000]. The latest NPS vehicle is named Acoustic Radio Interactive Exploratory Server (ARIES). This vehicle is a student-research test bed for shallow-water minefield-mapping missions, operating in the literal ocean. Currently the vehicle operates regularly in Monterey Bay [Grunesien 2002].

2. Dimensions and Endurance

The vehicle weighs 225 Kg and measures approximately 3 m long wide and 0.25 m high. The hull is constructed of 6.35 mm thick type 6061 aluminum and forms the main pressure vessel that house all electronics, computers and batteries. A flooded fiberglass nose is used to house the external sensors, key-controlled power “on/off” switches and status indicators. ARIES is capable of a top speed of 3.5 knots and is powered by six 12-volt rechargeable lead-acid batteries. Vehicle endurance is approximately 4 hours at top speed, with 20 hours endurance under “hotel load” only. The ARIES is primarily designed for shallow-water operations and can operate safely down to depths of 30 meters [Oceans 2000].

3. Propulsion and Motion Control Systems

Main propulsion is achieved using twin ½ Hp electric drive thrusters located at the stern. During normal submerged flight, heading and depth are controlled using upper bow and stern rudders plus a set of bow planes and stern planes. Since the control fins are ineffective during slow (or zero) forward-speed maneuvers, vertical and lateral cross-body thrusters are used to control surge, sway, heave, pitch and yaw motions [Oceans 2000].

23
4. Navigation Sensors
The sensor suite used for navigations includes a 1200 kHz Instruments (RDI) Navigator Doppler Velocimeter Log (DVL) that also contains a TCM2 magnetic compass. This instrument measures the vehicle ground speed, altitude, and magnetic heading. Angular rates and accelerations are measured using a Systron Donner 3-axis Motion pak IMU. While surfaced, Global Positioning System (GPS) inputs is provided by a carrierphase differential GPS (DGPS CP) system, available during surfaced operation to correct any navigational errors accumulated during the submerged phases of a mission [Oceans 2000].

5. Sonar and Video Sensors
Tritech ST725 scanning sonar and an ST1000 profiling sonar is used for obstacle avoidance and target acquisition/reacquisition. The sonar heads can scan continuously through 360 degree of rotation or swept through a predefined angular sector. A fixed-focus wide-angle video camera is located in the nose and is connected to a DVC recorder. The computer is interfaced to the recorder that controls on/off and start/stop record functions. While recording images, data for date, time, vehicle position, depth and altitude is superimposed on the video image [Oceans 2000].

6. Vehicle/Operator Communications
Radio modems are used for high bandwidth command, control and system monitoring while the vehicle is deployed and surfaced. While submerged, an acoustic modem is used for low-bandwidth communications. In the laboratory environment, a 10 Mbps thin-wire Ethernet connection is used for software development and mission data upload and download [Oceans 2000].

7. Computer Hardware Architecture
The dual-computer system unit measures approximately 28 x 20 x 20 cm. It consists of two Ampro Little Board 166 MHz Pentium computers with 64 MB RAM, four serial ports, a network adapter and a 2.5 GB hard drive each. Two DC/DC voltage
converters for powering both computer systems and peripherals are integrated into the computer package. The entire computer system draws a nominal 48 Watts. Both systems use TCP/IP sockets over thinwire Ethernet for inter-processor communications as well as connections to an external LAN. The sensor data-collection computer is designated QNXT. The second is named QNXE and executes the various auto-pilots for servo-level control [Oceans 2000].

8. Computer Software Architecture

The ARIES AUV uses a tri-level software architecture called the Rational Behavior Model (RBM). RBM divides the responsibilities into areas of open-ended strategic planning, soft-real-time tactical analysis and hard-real-time execution-level control. The RBM architecture is modeled after a manned submarine operational structure. The correspondence between the three levels and a submarine crew is shown in Figure 14 below.

![Rational Behavior Model](image)

Figure 14. Relational Behavior Model tri-level architecture hierarchy with level emphasis and submarine equivalent listed [Holden 1995].

This figure represents the tri-level software hierarchy with level emphasis and submarine equivalent listed. The Execution Level assures the interface between hardware and software. Its tasks are to maintain the physical and operational stability of the vehicle, to control the individual devices and to provide data to the tactical level. These tasks are currently performed by on-board host QNXS computer. The Tactical Level
provides a software level that interfaces with both the Execution Level and the Strategic Level. Its chores are to give to the Strategic level indications of vehicle state, completed tasks and execution level commands. The Tactical level selects the tasks needed to reach the goal imposed by the Strategic level. It operates in terms of discrete events.

The Strategic Level controls the completion of the mission goals. The mission specifications are inside this level.

H. RELATED RESEARCH

1. History and Contributors

The AUV Workbench is the result of the combined efforts of several past and present NPS students and faculty. Adrien Gruneisen and Yann Henriet [Grunesien 2002] developed the first version of the workbench based on the dissertation research of Don Brutzman [Brutzman 1994]. It executes AUV missions while providing the user with a “close-up” view of the vehicle so the vehicle dynamics can be observed.

Doug Horner added support for a non-validating XML-based mission script, an obstacle avoidance algorithm, and support of mission planning using plain text format. The original vehicle execution was re-written using Java network communications. Of note, the XML-based mission script format has been superseded by the Hawkins and Van Leuvan thesis effort in 2003 [Hawkins 2003] and the Ayala thesis on AUV Java execution using Distributed Interactive Simulation (DIS) supersedes the older vehicle execution [Ayala 2002]. The obstacle avoidance module does not compute the path dynamically. It generates a path based on a list of known obstacles and the preloaded AUV mission script. The initial efforts were to implement a simple standalone application for pre-mission visualization and as a quick prototype for proof-of-concept. Therefore there was no network connectivity (e.g., through IEEE Distributed Interactive Simulation DIS protocol) and no collaboration tools were introduced.
I. SUMMARY

The NPS AUV Workbench integrates years of research work by students and faculty. To take the AUV Workbench to the next step, it is necessary to streamline these efforts and employ the best practices of software development. It is through such an approach that important knowledge can be retained and continued research and development can be promoted.
III. AUV WORKBENCH

A. INTRODUCTION

The AUV Workbench is a common mission planning and analysis tool for AUVs. It supports physics-based AUV modeling and visualization of vehicle behavior and sensors in all mission phases: pre-mission, post-mission and ongoing mission visualization. The AUV workbench consists of four main modules. These modules communicate with each other either directly or over the network for required interaction. The individual modules are responsible for four distinct functions: mission execution; virtual world dynamics modeling and feedback; mission planning and generation; and 2D/3D mission visualization. This chapter provides details regarding the design and implementation of the modules developed under this thesis, namely mission planning, XML-based mission script and the general Workbench interface. The topics on mission execution and virtual world modeling and feedback are also explained. Two supporting modules are included to facilitate information exchange among human operators as well as agents.

B. DESIGN RATIONALE

1. Graphical User Interface (GUI)

The Workbench user interface is divided into four distinct sections. Text or XML-based mission scripts are loaded as part of the Mission panel, in the upper left pane. Clicking on List and Text tabbed pages toggle between the various modes of the mission script. The Mission Planner and three-dimensional visualization displays provides the viewing panel on the upper right pane. The modules, Execution and Dynamics, to model the robot and its virtual environment are found at the bottom of the Workbench window. By default, the application toolbar is located on the right side. It allows the addition of custom applications to be added and launched in a separate process. Of note, the toolbar is both dock-able and float-able. The user can choose to dock the toolbar on any side of the Workbench application, or keep it floating.
Figure 15. AUV Workbench application user interface.

Figure 16. List of modules and libraries required to build the AUV Workbench application.
2. Project Structure

The AUV Workbench is Java-based and was implemented using a componentized framework. The project structure is shown in Figure 17. At the top level, the core directories are /bin, /lib, /execution, /dynamics, /Models, /Scripts, /dataweb and /dataim. The Java packages and classes that make-up the Workbench are kept in /bin directory. The list of required libraries such Apache Xerces for XML parsing are stored in /lib. The robot control and virtual environment modules are found in /execution and /dynamics respectively. To facilitate the user to get started quickly, sample models and mission scripts are distributed in /Models and /Scripts directories. /dataweb and /dataim store files that are used by the web server and Jabber instant messaging modules.

![Figure 17. AUV Workbench project directory structure.](image)

3. Source Code and Runtime Package Structure

The directories in Figure 18 illustrate the directory structure of the AUV Workbench Java source and runtime packages.

![Figure 18. AUV Workbench application (AUVW) Java source and binary directory structure.](image)
This setup provides ease of development and subsequent maintenance of the different modules. `/main` contains the source code of the main user interface and the 3D visualization. It is responsible for the rendering of the entire user interface including the placements of the user interfaces for the various modules. The two-dimensional mission planner module is placed in `/mission`. Jabber instant messaging and web server modules are placed in `/im` and `/web` respectively. Common utilities and procedures are kept in `/util`.

4. Configuration File

Although the componentized framework works well for developers, day-to-day
users of the Workbench require something simpler so that they can make changes to the
system easily and move on to their actual work. Therefore an XML-based configuration
file has been introduced. This file is located in the same directory as the application
executeable. Adding a new tool is as simple as opening the configuration file,
AUVWorkbenchConfiguration.xml, adding a new entry under the Application stanza
section and re-starting the Workbench. Details on adding new tools to the application
toolbar will be discussed in a subsequent section.

5. **ANT – JAVA-based Build Tool**

Ant is a Java-based build tool. In theory, it is kind of like Make, without Make's wrinkles and with the full portability of pure Java code. According to Ant's original author, James Duncan Davidson, the name is an acronym for "Another Neat Tool". Ant builds projects specified by an XML build file. The Build file defines Build targets and Build tasks. For example, a build file might contain separate targets for building a project and generating Javadoc. The individual targets or the default target for the project can be executed using the Ant build file (http://ant.apache.org accessed January 2004).

The build.xml for AUV Workbench is given in Figure 26.

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<!-- ANT Build Script for the AUV Workbench Project -->
<project name="AUVWorkbench" default="bin" basedir="/">

<!-- "" "" Project Standard Properties "" "" -->
```
<property name="project.name" value="AUVWorkbench" />
<property name="project.version" value="0.1" />

<!-- Java source and package directory -->
<property name="src.dir" value="${basedir}/src" />
<property name="src.main.dir" value="${src.dir}/main" />
<property name="src.mission.dir" value="${src.dir}/mission" />
<property name="src.im.dir" value="${src.dir}/im" />
<property name="src.web.dir" value="${src.dir}/web" />
<property name="src.util.dir" value="${src.dir}/util" />

<!-- Library dependencies -->
<property name="lib.dir" value="${basedir}/lib" />

<!-- Java compiled and package directory -->
<property name="build.dir" value="${basedir}/bin" />

description="Compiles the source, builds the jar files, generates the Javadoc HTML pages and creates distribution files (.zip).">
</target>
</project>

Figure 26. AUV Workbench ANT build.xml used to compile and build the application.

Here is a detailed examination of the build.xml file to explain what it does:

- **project**: includes a project name, the default target to run if none of the other individual targets are run, and the location of the base directory (/bin).

- **properties**: Ant targets and tasks are typically “property-aware”. Properties are also used to pass parameters to tasks without overriding the existing properties in the build file. To get the value of a property, use “${<property name>}” syntax.

- **clean** target: deletes existing compiled packages’ directories and the project JAR file.

- **prepare** target: creates the package directories for the compiled classes.

- **compile** target: initiates the clean target first (using the depends keyword), which in turn initiates clean target, then compiles the Java source files and puts the generated .class files in the build directory.

- **dist** target: initiates the compile target first and creates a JAR file in that directory.

- **javadoc** target: creates the JavaDoc for the project and also generate a compressed copy of the Java documentations.

- **zip** target: Compress all the project dependencies into a single ZIP file.

- **all** target: initiates dist, javadoc and zip targets.

To activate the individual targets, use “ant <target name>”; e.g., “ant compile”. By default, Ant looks for “build.xml”. To specify a different Build file name, use “ant –buildfile <Build filename> <target name>”

C. MISSION PLANNING

1. Overview

The AUV Workbench supports both a simple, text-based mission script as well as the use of XML-based mission scripts. This section presents the details of the XML-based mission script and the tools to author them.

2. AUV XML-based Mission Control Script

The XML AUV command language is defined using XML schema [Hawkins 2003]. In general the command language enables the explicit declaration of an entire mission using execution-level commands, the ad-hoc definition of a mission by providing individual commands asynchronously (in the form of individual single command element documents), mission data archiving (telemetry, control orders, sonar

41
data, derived sensor-based data, etc.), and communication between various levels of the control architecture (execution, tactical, strategic levels) or between multiple autonomous vehicles, software agents, or human controllers. This mission control language is a subject of ongoing research and is likely to change significantly in the next version.

A valid document will have a missiondata, mission, report or individual command root element. A missiondata element can contain up to one mission element and an arbitrary sequence of individual command, report, telemetry, control order and sonar data elements. A mission element will contain one or more command elements in any order.

**a. “MissionData” Element**

Autonomous vehicle relevant info: mission commands, control orders, telemetry, sonar results, and/or reports to and from internal or external entities (other vehicles, agents, or human controllers).

```

Figure 28. A sample XML-based mission script [after Hawkins 2002].

**3. Mission Script Authoring Tools**

The two-dimensional Mission Planner module provides the means to graphically and intuitively display and author the XML-based AUV mission scripts. The user is presented with a two-dimensional planar view of the mission. This module has a mission canvas whereby a user can easily manipulate positional information pertaining to the script. Extra effort was made to ensure that it is context-sensitive and is at the same time
as intuitive as possible. For example, adding or deleting a waypoint is a simple right mouse click, double clicking on a point displays the attributes associated to it. Each mission command has its own set of attributes and its respective user interfaces to manipulate them.

Additionally, mission points can be edited manually or adjusted by using the drag feature. Minor, but useful features such as snapping to the grid display were added too.

![XML-based mission script display and 2D Mission Planner. The mission commands are displayed as a list on the left and the positional data are displayed graphically on the right.](image)

Table 9. Details of mouse right-click popup menu items.
A two-dimensional viewer was developed to facilitate mission generation since it is easier for a user to manipulate in 2D space than 3D space. Depth information can be displayed alongside each 2D point or through the use of color coding. While the AUV mission script has a rich set of commands including non-positional ones, only mission commands that contain positional information are graphically displayed since they contain x-y coordinates. To address this deficiency, an XML-based Mission List module was developed to run alongside the 2D Mission Planner. The Mission List module is
essentially a list of all mission commands in the current script. The two graphical views are currently linked dynamically with changes made on either side automatically reflected on the other.

Figure 34. Right-click popup menu on the Mission List display.

D. EXECUTION AND DYNAMICS PROCESSES

1. Execution

The mission execution module uses the same software that is on board the actual AUV. Utilization of the actual AUV software facilitates the development of control equations and algorithms, and enables the realistic rehearsal and fine-tuning of missions in a benign lab environment prior to attempting their execution in open water. By querying the mathematical model of the virtual world for telemetry data rather than onboard sensors, the AUV software can create for itself the illusion that it is operating in the water and the software will behave accordingly.

The AUV Workbench currently has two versions of the AUV execution software. The primary differences are the implementation programming language (compiled C code and Java) and useable command language options. The Java version supports both simple textual and XML-based mission scripts [Ayala 2002], whereas the compiled C version only supports text-based scripts. The former is preferred due to its support for XML-based mission scripts. XML helps to remove any ambiguity in the names of the commands and provides error-checking through validation.
The vehicle behavior can be adapted to other vehicles by adjusting the control constants and by adding, deleting or changing control equations. The control algorithms can be tested and visualized with various mission scripts, against known hydrodynamics models. Any effort to provide precision control for an AUV requires an accurate estimation of both the vehicle’s physical and hydrodynamic parameters. Here a vehicle model for controlled steering behaviors was developed and the hydrodynamic parameters were calculated from actual data obtained from operations. [Johnson 2001]

2. Dynamics

The virtual world dynamics thread implements the AUV hydrodynamics mathematical model. When passed a telemetry string from the AUV execution thread, the model is applied, and then a follow-on telemetry string is generated to pass back to the AUV. Additionally, a Distributed Interactive Simulation (DIS) packet is broadcast over the network to drive the visualization thread of the workbench (as well as any other DIS-enabled visualization application that may be on the network). In addition to hydrodynamics modeling, the dynamics thread contains classes that are utilized to model the vehicle’s onboard sensors. Sonar data (or that from any other onboard sensor) can therefore be derived and encapsulated within the telemetry string and DIS packets to allow for realistic feedback to the AUV execution software, and accurate mission visualization by the human operator. As with the execution software, the hydrodynamics mathematical model and sensor models currently in use were developed to model the vehicles operated by NPS, but can be arbitrarily adapted to other vehicles simply by modifying the control constants.

The effects of the surrounding environment on a robot vehicle are unique to underwater domain. Understanding these forces is a key requirement in the development and control of the vehicle behavior. The dynamics program Java source code is designed to substitute for the natural environment effects on the AUV. It also provides an estimate of the AUV behavior in the water by performing a series of calculations using physical laws. By communicating with the execution code via a network socket, the telemetry data or state variables of the vehicle are collected. Dynamics apply several equations of motions, forces, and accelerations to the hydrodynamics model and the data received
from the execution code. The data produced by dynamics is then sent back to execution, where it is analyzed and appropriate action commands are then given to the respective actuators based on that data. This is a important and difficult part in the real-time simulation in a virtual world [Ayala 2002].

The 3D visualization algorithms in the dynamics code allow the update of 3D scenes developed using X3D-Edit. These scenes are viewed through an Internet browser using a plug-in VRML viewer.

E. **3D VISUALIZATION**

1. **Design and Implementation**

   The visualization portion of the workbench contains a 3D viewer that utilized X3D or VRML models of the AUV and its virtual environment. The 3D viewer is developed using an open-source 3D library, Xj3D. By reading and interpreting the incoming DIS packets from network, the viewer automatically animates the vehicle. Through the 3D display, the user is provided with visual feedback on control settings, sensor effectiveness and utilization.

2. **User Interface**

   The 3D display module is located in the upper right pane of the application window. It is on the tabbed page component alongside the 2D mission viewer module.
F. WEB SERVER

1. Design and Implementation

In a collaborative environment, there is always a need to share information. For example, data such as current position and list of obstacles encountered can be published and easily accessible to both human operators and other planners who may or may not be using the Workbench. Dissemination of information via web server is well tested and has proven to be a stable and efficient solution. One possible way to web-enable the Workbench is to deploy a full-fledged open-source web server such as Apache Tomcat, but this approach introduces additional deployment, administrative and maintenance issues. Therefore a scaled down but fully functional multi-threaded web server has been incorporated as a module in the AUV Workbench. This allows publishing of information directly from the Workbench. At the same time, the web server is able to process uploaded files via HTTP POST. Through the use of HTTP GET and HTTP POST, it is possible to incorporate message and file sharing capability via HTTP into the Workbench. It has been proposed that the HTTP file transfer mechanism be used for “mirroring” of mission data between individual Workbench applications and a central archival server.
### Table 10. Sample web server directory structure.

2. **User Interface**

The web server module is located on the lower pane of the Workbench application, on the *Web Server* tabbed page. A set of default values, such as document default directory and port number, are given. Simply clicking on the *Start* button invokes the web server. To test whether the web server is working, open a hyperlink to the host or machine that the AUV Workbench application is running on, using an Internet browser; e.g., [http://localhost:80/index.htm](http://localhost:80/index.htm).

G. Jabber Instant Messaging

1. Design and Implementation

To facilitate near-realtime communications, a customized Java-based Jabber client is incorporated into the Workbench. The customized client is able to handle simple plain-text messages and binary file data (e.g., images and XML-based mission script). The XTC Monitor module is built on top of the customized Jabber client. An open-source Jabber library, JiveSoftware Smack library is used [JiveSoftware 2003]. Section H covers the XTC Monitor in a greater depth. Worth noting is that the customized Jabber module is introduced for XTC Event Monitoring and packaging of a binary file. It is not to replicate the simple human-to-human text messaging capability found in standard Jabber clients.

<table>

2. **User Interface**

This module is located on the lower pane of the Workbench application, on the XTC Monitor tabbed page. The application reads in the Jabber settings under the Jabber stanza of the configuration file (Figure 25). This set of values is populated in the edit-boxes within the Settings tabbed page (Figure 39). Once the password is set, clicking on Connect button establishes a session with the Jabber server specified in the domain edit-box. At the same time, the client will start to listen for messages in the chat room (specified in Chatroom edit-box).

H. XTC EVENT MONITOR

1. Design and Implementation

The XTC Event Monitor module is comprised of three sub-modules. IMSend and IMReceive are the two basic ones used for instant messaging. IMSend is responsible for
the packaging of binary data and sending it out. It is able to handle single or multiple file attachments. The outgoing message may be addressed to a specific Jabber user (i.e., peer-to-peer) or a chat-room. **IMReceive** listens for posted messages. Again, it is listening to either a particular Jabber user or a chat-room. When there is an incoming message, it parses it and using event monitor criteria defined in the **IMCriteria** sub-module, it generates the appropriate response or alert. **IMReceive** is able to re-generate packaged binary files within a Jabber message (i.e., sent by **IMSend** or similar programs). A sample XHTML message with encoded binary file data is shown in Figure 40. See Chapter IV for details on the design and implementation of the message package module. Next, this section discusses how the incoming events are processed, how alerts are raised and ways messages can be sent.

```xml
<message id="Seu4-4" to="savage@conference.xchat.movesinstitute.org"
  type="groupchat" from="avrboto@aurthur.cs.aps.navy.mil">
  <body>
    <html xmlns="http://jabber.org/protocol/xhtml-im">
      <agentJabber>
        <!-- Payload -->
        <AgentXPayload>
          <checksum="12345678">
            <content-transfer-encoding>base-64</content-transfer-encoding>
            <data>
              <![CDATA[
                <html>
                  <head>
                    <title>Sample XHTML Message</title>
                  </head>
                  <body>
                    <!-- Compressed and base-64 encoded data (textual & binary) -->
                    <!-- Hyperlinks to storage locations -->
                  </body>
                </html>
              ]]>
            </data>
          </AgentXPayload>
        </checksum>
      </body>
    </html>
  </body>
</message>
```

Figure 40. Sample XHTML message with encoded binary file in **CDATA** section.

The third sub-module, **IMCriteria** is for the definition of event monitoring criteria. For this thesis, regular expressions are used to define the watch events. **Watch Event** determines whether an incoming message matches the regular expression patterns. If a match is found, respective alerts are raised.

55
2. **User Interface**

As part of the customized Jabber client, *XTC Monitor* functionalities are found on the same *XTC Monitor* tabbed pages.

![Instant Messaging user interface to package and send text and files.](image)

**Figure 41.** Instant Messaging user interface to package and send text and files.
Figure 42. Instant Messaging user interface to display list of incoming messages.

Figure 43. Instant Messaging user interface to define the criteria to alert the user.
3. XTC Event Monitoring Configuration

The settings for the event monitor module are XML-based and included under the XTCMonitor stanza of the AUVWorkbench configuration file. There are two types of event monitors: There is one instance of default event monitor (MonitorDefault) and multiple instances of Jabber user-specific event monitors (Monitor). There can be one or more Alert elements associated to a WatchEvent element. These alerts, if enabled (i.e., enabled attribute set to true), will be raised in a consecutive order.

```xml
<XTCMonitor>
  <MonitorDefault keywordSubject="mine, bomb, torpedo"
  keywordBody="nice, mine, bomb, torpedo, location, CVN62, SNN12, DDG51">
    <WatchEvent name="Mine" desc="Look out for Mines"
    expr=".*(?i)MINE[s|S]? .*[ ]{2,}(\d*),[ ]{0,2}(\d*),[ ]{0,2}(\d*)[
    ]?+">
      <Alert type="visual" src="image/mine.gif" enabled="true"/>
      <Alert type="sound" src="sound/alert.wav" enabled="true"/>
      <Alert type="url" src="C:/auv/Workbench/doc/index.htm"
      enabled="false"/>
    </WatchEvent>
    <WatchEvent name="Ship" desc="Look out for Ships"
    expr=".*(?i)SHIP[s|S]? .*[ ]{2,}(\d*),[ ]{0,2}(\d*),[ ]{0,2}(\d*)[
    ]?+">
      <Alert type="visual" src="image/ship.gif" enabled="true"/>
    </WatchEvent>
    <WatchEvent name="Location" desc="Look out for Locations"
    expr=".*(?i)LOCATION[s|S]? .*[ ]{2,}(\d*),[ ]{0,2}(\d*),[ ]{0,2}(\d*)[
    ]?+" alert=""/>
  </MonitorDefault>
  <Monitor jid="savage@conference.xchat.movesinstitute.org" desc=""
  datetimeStart="" dateTimeEnd="" keywordSubject="mineX, bomb, torpedo"
  keywordBody="mineX, bomb, torpedo, location"/>
  <Monitor jid="auvrobot@surfaris.cs.nps.navy.mil" desc=""
  datetimeStart="" dateTimeEnd="" keywordSubject="urgent, problem"
  keywordBody="damage, sinking, surface"/>
</XTCMonitor>
```

</tbody>
</table>

Table 16. XML tagset to configure XTC event monitoring.

4. **How Incoming Events are Handled**

Upon application startup, the list of default and user-specific event monitors are loaded. For each of the monitors, there can be one or multiple watch events (in *WatchEvent* tag). The check to determine whether a watch event is matched against an incoming event is via the regular expression defined within the *expr* attribute. Once there is a match, the list of available alerts under the *WatchEvent* element is raised. There are three types of alerts: “visual”, “sound” and “url”. The alert type is depicted under the *type* attribute of the *Alert* element. In addition, the *src* attribute defines the source location of the alert; e.g., image or sound path.
For this thesis, the following alert mechanisms are implemented:

a. **Visual Alert**

The 2D Mission Planner module handles this alert. A new target object is added to the list of targets, maintained by the module. Next the target is plotted on the 2D display using the image specified in the `src` attribute.

```
<Alert type="visual" src="image/mine.gif"/>
```

Figure 46. A sample alert of type “visual”.

b. **Sound Alert**

This alert is handled within the Event Monitoring module. If the source path of the alert exists, a sound is played back.

```
<Alert type="sound" src="sound/alert.wav"/>
```

Figure 47. A sample alert of type “sound”.

c. **URL or Hyperlink Alert**

The Event Monitoring module opens an application to display the hyperlink or file specified in the `src` attribute. The application is chosen based on the content type of the hyperlink (e.g., .htm) or file (e.g., .bmp or .txt). For example with the following alert (Figure 48), it is of type “url” and the source file (“C:/auv/Workbench/doc/index.htm”) is of “text/html” content type (determined from the file extension). Based on the “text/html” content type, the module then looks for the associated application to render it.

```
<Alert type="url" src="C:/auv/Workbench/doc/index.htm"/>
```

Figure 48. A sample alert of type “url”.

The list of available applications is defined in the AUV Workbench configuration file under the `Application` stanzas. A sample of the `Application` stanza is given in Figure 49.
Figure 49. A sample list of applications defined in *Application* stanzas that can be invoked.

An overview of the process of event monitoring of instant messages and the triggering of alerts is given in Figure 50.

Figure 50. Instant messaging event monitoring and alert mechanism process via standard Jabber client.
5. How Events/Messages are Generated

a. Free-form Text Using Standard Jabber Clients

Using a standard Jabber client such as Rhymbox, a human operator keys in the message “A mine is found at position (100, 100, 5)” and sends it. With free-form text, the receiving party (i.e., XTC Monitor) needs to extract the necessary pieces of information from the chatter. For this thesis, a simple sentence parsing module using Java's Regular Expression Parser was implemented. A more precise and robust extraction module that utilizes Natural Language Processing can be developed in the future. This technique is error-prone especially when the operator is under stress. This in turn leads to additional verification at the software end to ensure that it is tolerable to minor errors such as missing spaces, characters or misplaced characters.

b. Structured Text

Message generation using a structured format is a preferred approach. The user is presented with a form (HTML or Java Swing application). This approach removes the need for a sentence parser and error checking, thus reducing message processing time. Data from structured text comes formatted and possibly validated at the server or client end. The receiving party only needs to extract the necessary portions of data based on a predefined schema. There are various ways that structured text can be captured:

- Capturing the data in the correct format manually by human operators. This is a tedious and error-prone process.
- Use of a customized client application to allow capture and validation of inputs from the operators.
- Use of a web page to allow the operators to key-in the required information. This method is preferred, as it only requires that there is access to a web browser and the web page since this will work as long as the human operator has access to the web page. This removes the need to deploy customized applications.
Advantage of using Instant Messaging protocol is that it allows both human operators and agents to interact in the same environment. Agent-specific data is stored in the XHTML sections of the message. These are not visible on normal Jabber clients, but are caught by agents that are listening for them and processed accordingly.

I. APPLICATION TOOLBAR

The application toolbar is highly configurable to allow users and developers alike to add new applications to the AUV Workbench. The toolbar is both floatable (Figure 52) to increase display real estate on the Workbench as well as dock-able to any side of the Workbench application. This provides a convenient way for users or developers to bundle frequently used applications. The capability is achieved through the use of an XML-based configuration file. The current version of the Workbench has two built-in features: the “About” dialog and the “Screen Capture” capability (i.e., the first two toolbar buttons). A sample application toolbar is seen below:

![Sample Application Toolbar]

Table 17. Details of Toolbar Buttons.

The XML-based configuration file is human-readable and nicely partitioned to allow the user to add or remove applications easily. The procedures to add a new application are given below:

- Locate and open the configuration file; e.g., `AUVWorkbenchConfig.xml`.
- Go to the section where the `Application` tags are defined.
- Make a copy of an existing `Application` set.
• Make the necessary changes to the attributes; e.g., name is the name that appears in the toolbar button, tooltip is the hint and image defines the location of the toolbar button image.

• Add the file types that this application can handle under content-type attribute. Set show attribute to “true” to display in toolbar.

• The param attribute defines the parameter to be passed into the application upon its startup; e.g., a hyperlink to be a web-page for a Internet browser application.

• Next add Command elements. These define the actual locations of the application. Upon clicking on the particular toolbar button, the AUV Workbench tries to look for the application from the possible list of Command tags provided. Once found, the application is invoked.

```xml
<Application name="Browse" tooltip="Web Browser" image="image/browser.gif" show="true" content-type="text/html" param="intranet.nps.navy.mil">
  <Command>C:/Program Files/mozilla.org/Mozilla/mozilla.exe</Command>
  <Command>C:/Program Files/Internet Explorer/IEXPLORE.EXE</Command>
</Application>
```

J. STORAGE, NETWORKING AND COMPRESSION

1. Naming Convention

Code conventions are important to programmers since 80% of the lifetime cost of a piece of software goes to maintenance. Software is hardly maintained for its whole life by the original author. Code conventions improve the readability of the software, allowing engineers to understand new code more quickly and thoroughly.

<table>
<thead>
<tr>

<td>.x3d</td>
</tr>
</tbody>
</table>

Table 19. File types and their suffixes.

Naming conventions make programs more understandable by making them easier to read. They can also give information about the function of the identifier—for example, whether it's a constant, package, or class—which can be helpful in understanding the code.

<table>
<thead>
<tr>

Figure 55. X3D Naming Convention [X3DHints 2004].
K. TOOLS AND PRODUCTS

1. Overview

This section provides a brief description on the applications that are bundled with the current version of AUV Workbench. There are two built-in functionalities in the Workbench’s application toolbar, namely the About and Screenshot buttons. As the name implies, the About button pops up an image that describes the AUV Workbench. The image can be easily changed by replacing the image named SplashScreen.jpg in the /image subdirectory. As a collaboration tool, there is always a need to share the current picture in the AUV Workbench. This may include a view of the mission script and the 3D view of the environment. Thus a fast one-button click screen-capture capability has been added to the Workbench.

Figure 56. Splash-screen poster image describing the AUV Workbench, produced by the author.

Figure 57. Screen-capture button on the Application Toolbar.
2. **Jabber Instant Messaging (IM) Client**

A useful tool to facilitate near-real time text messaging between human operators is an Instant Messaging (IM) client. Through the Jabber client, a developer can log onto a AUV Workbench chat-room and post questions or answers to fellow developers. Similarly, human operators are able to use the Jabber client to post mission related information (e.g., location of a mine). All messages posted via the Jabber clients can be logged on the Jabber server. This is useful for post-mission analysis by operational users or consolidation of a trouble-shooting guide for developers.

```xml
<Application name="Jabber"
    tooltip="Instant Messaging Client" image="image/jabber.gif">
    <Command>C:/Program Files/RhymBox/RhymBox.exe</Command>
    <Command>D:/Program Files/RhymBox/RhymBox.exe</Command>
    <Command>C:/Program Files/IM/RhymBox/RhymBox.exe</Command>
</Application>
```

Figure 58. Jabber application setting in the AUV Workbench configuration file

RhymBox is a Jabber client for instant messaging. The Jabber network employs a distributed and secure infrastructure. The Jabber protocol is based on the IETF supported XMPP. Jabber is also linked to legacy services (e.g., Yahoo!, MSN, AIM, ICQ, etc).

![Jabber client interface](image/jabber_gui.png)

Figure 59. Rhymbox Jabber client main user interface.
Figure 60. Rhymbox Jabber client “Chat-room” interface.

Figure 61. Rhymbox Jabber client “Settings” interface.
3. Internet Browser

One of the essential tools required in a collaboration environment is an Internet Browser. The browser allows both users and developers to access the World Wide Web to find information.

Once the “Browser” button is clicked, the application looks for the first available browser through the list of possible browser applications, i.e., defined in the Command
stanza. A default web-page can be specified using the param attribute. This allows users to be directed to the relevant web-page (e.g., AUV Workbench development) upon browser startup.

```xml
<Application name="Browse" tooltip="Web Browser"
    image="image/browser.gif"
    show="true" content-type="text/html"
    param="intranet.nps.navy.mil">
    <Command>C:/Program Files/mozilla.org/Mozilla/mozilla.exe</Command>
    <Command>D:/Program Files/mozilla.org/Mozilla/mozilla.exe</Command>
    <Command>C:/Program Files/Internet Explorer/IEXPLORE.EXE</Command>
    <Command>D:/Program Files/Internet Explorer/IEXPLORE.EXE</Command>
</Application>
```

Figure 64. Internet Browser entry in the AUV Workbench configuration file.

4. **X3D-Edit**

X3D-Edit is a graphics file editor for Extensible 3D (X3D) Graphics that enables simple error-free editing, authoring and validation of X3D or VRML scene-graph files. Context-sensitive tooltips provide concise summaries of each VRML node and attribute. These tooltips simplify authoring and improve understanding for novice and expert users alike.

X3D-Edit uses the X3D 3.0 tagset defined by the X3D 3.0 Document Type Definition (DTD) in combination with Sun's Java, IBM's Xeena XML editor, and editor profile configuration files. More information on X3D-Edit can be found at [http://www.web3d.org/x3d/content/README.X3D-Edit.html](http://www.web3d.org/x3d/content/README.X3D-Edit.html).
5. **jEdit**

jEdit is a cross-platform programmer's text editor written in Java, being developed by Slava Pestov and others. It is available online at [http://www.jedit.org](http://www.jedit.org). It has an easy to use interface that resembles that of many other Windows and MacOS text editors. It is also highly customizable, and contains a “plugin” architecture that allows its features to be extended by additional programs.
jEdit contains a large assortment of features for manipulating source code, markup text, and other text files. As a programmer's text editor, it also has many features to help programmers manage their projects and work with other programming tools.

![jEdit User Interface](image)

**Figure 67.**  jEdit User Interface running on Windows platform.

Text editing can be different on different operating systems (Carriage Return versus Carriage Return-Line Feed differences), and also some default text editors are notoriously poor (e.g. Windows Notepad), jEdit is bundled with the NPS AUV Workbench. This tool ensures that users can perform simple editing tasks on configuration and output files, thus simplifying use and remote debugging support.

A plugin is an application that is designed to work with jEdit by providing additional features that can be used from within the main program. Often the plugin will provide a visible user interface in a window that can be docked to jEdit's main view window. There are currently over 60 publicly available plugins that provide such services as a Java source code browser, a command-line shell, templated text insertion, and source code project management. They can be downloaded, installed, and kept current from within jEdit's “Plugin Manager”.

6. AUV Data Server

The NPS AUV Data Server (ADS) is a tool for post-mission analysis. It is able to read the actual AUV telemetry data from several different AUV sources and generate a 3D view of the mission in VRML or X3D. ADS has processed data retrieved from the Woods Hole Oceanographic Institution (WHOI), REMUS, Florida Atlantic University Ocean Explorer (OEX), and NPS ARIES AUVs. ADS parses robot telemetry as well as mission asset (track), bathymetry and contact reports. These data files are converted into Message Transfer Format (MTF) message format and imported into Mine Warfare Environmental Decision Aids Library (MEDAL). The MEDAL format is used by the US Navy to evaluate asset positions, mine-like contacts, snipped images of those contacts identified as mines and bathymetry maps. It provides a network message interface to GCCS MEDAL systems and also produces X3D mission visualizations.

L. SUMMARY

The NPS AUV Workbench has integrated years of work by students and faculty to form a stable code base whereby continued research and development can be supported. The flexibility of the Workbench has made it simple enough for day-to-day users to get started, and at the same time allowed developers to add new tools and modules with ease. During the course of this thesis, two new modules were added. One supports Recursive Ray Acoustics (RRA) visualization and was by LT Scott Rosetti, USN. The other module supports the compression of mission data using XML Schema-based Binary Compression (XSBC) [Serin 2003] created by LCDR Duane Davis, USN, on.
IV. MESSAGE EXCHANGE TECHNIQUES AND TRANSPORT PROTOCOLS

A. INTRODUCTION

The major advantages of XML for interoperability of data are its extensibility and its ability to represent all forms of data, including graphics such as Virtual Reality Modeling Language, VRML or Extensible 3D Graphics (X3D) in text format. As systems get more complex, the need to transfer binary data as part of the XML document arises. This chapter presents possible ways to efficiently package and transport both textual and binary XML-based data via Extensible Messaging and Presence Protocol (XMPP). In addition, the design and technical implementations of possible applications using this data exchange technique are discussed.

B. COMPRESSION AND DECOMPRESSION USING JAVA.UTIL.ZIP

Compression and decompression are often applied to data to reduce network traffic during transportation and improve the performance of client/server applications. Likely candidates for applying compression and decompression are text-based files such as Scalable Vector Graphics (SVG), VRML and X3D, along with uncompressed image formats, for example 24-bit image files.

This section presents a brief introduction to data compression and decompression, and shows how to compress and decompress data (in physical files and objects) efficiently and conveniently from within Java applications using the java.util.zip package.

While it is possible to compress and decompress data using tools such as WinZip, gzip, and Java ARchive (JAR), these tools are used as standalone applications. It is possible to invoke these tools as separate applications from within a Java application, but this is not a portable, straightforward or efficient approach. Drawbacks of launching compression applications are especially problematic if data needs to be compressed and decompressed on the fly.

The java.util.zip package for zip-compatible data compression provides classes to read, create, and modify ZIP and GZIP file formats. The package also provides utility classes for computing checksums of arbitrary input streams that can be used to validate
input data. This package provides one interface, fourteen classes, and two exception classes. For file manipulations, there are three main classes for the manipulation of objects and two classes for data streams.

1. Zipping Files

The java.util.zip package provides classes for data compression and decompression. The main classes are ZipInputStream for reading ZIP files and ZipOutputStream for writing ZIP files. The ZipInputStream class reads ZIP files sequentially, whereas the class ZipFile reads the contents of a ZIP file using a random access file internally so that the entries of the ZIP file do not have to be read sequentially.

<table>
<thead>

</tr>
</tbody>
</table>

Table 21. Classes for File Compression and Decompression.

a. Compressing and Archiving Data to a ZIP File

The ZipOutputStream can be used to compress data to a ZIP file. The ZipOutputStream writes data to an output stream in a ZIP format. A sample procedure is given below.

```java
import java.io.*;
import java.util.zip.*;
public class ZipStreamCS {
    static final int BUFFER = 2048;
    public static void main (String argv[]) {
        try {
            BufferedInputStream origin = null;
            FileOutputStream dest = new
                FileOutputStream("ZipStreamCS.zip");
            CheckedOutputStream checksum = new
                CheckedOutputStream(dest, new Adler32());
            ZipOutputStream out = new
                ZipOutputStream(new
                    BufferedOutputStream(checksum));

            byte data[] = new byte[BUFFER];

            // get a list of files from current directory
            File f = new File(".");

            // list of files to be zipped
```
String files[] = {"sample.bmp", "links.txt"};
// or retrieve all files in current directory, f.list();

for (int i=0; i<files.length; i++) {
    System.out.println("Adding: "+ files[i]);
    FileInputStream fi = new FileInputStream(files[i]);
    origin = new BufferedInputStream(fi, BUFFER);
    ZipEntry entry = new ZipEntry(files[i]);
    out.putNextEntry(entry);
    int count;
    while((count = origin.read(data, 0, BUFFER)) != -1) {
        out.write(data, 0, count);
    }
    origin.close();
}
out.close();
} catch(Exception e) {
    e.printStackTrace();
} }
} // ZipStreamCS

Figure 74. File compression code snippet.

### b. Decompressing and Extracting Data from a ZIP File

The `java.util.zip` package provides classes for data compression and decompression. The `java.util.zip` package provides a `ZipInputStream` class for reading ZIP files. Below is the sample code to perform decompression:

```java
import java.io.*;
import java.util.zip.*;

public class UnZipStreamCS {
    public static void main (String argv[]) {
        try {
            final int BUFFER = 2048;
            BufferedOutputStream dest = null;
            FileInputStream fis = new FileInputStream(argv[0]);
            CheckedInputStream checksum = new CheckedInputStream(fis, new Adler32());
            ZipInputStream zis = new ZipInputStream(new BufferedInputStream(checksum));
            ZipEntry entry;
            while((entry = zis.getNextEntry()) != null) {
                System.out.println("Extracting: "+entry);
                int count;
                byte data[] = new byte[BUFFER];
                // write the files to the disk
                FileOutputStream fos = new FileOutputStream(entry.getName());
            }
        }
    }
} // UnZipStreamCS
```
c. ZIP File Properties

The ZipEntry class describes a compressed file stored in a ZIP file. The various methods contained in this class can be used to set and get pieces of information about the entry. These methods include retrieving information such as original size, compressed size and time of compression. This class is used by the ZipFile and ZipInputStream to read ZIP files, and the ZipOutputStream to write ZIP files.

2. Gzipping Objects

The ZIP format is record-based, thus suitable for file-based compression, but is not suited to manipulate objects or data streams. The GZIP is more appropriate as it operates on a single stream of data making it well suited for transferring large objects over sockets. The objects are compressed before sending across the network and decompressed upon arrival at their destination.

<table>
<thead>
<tr>
<th>S/N</th>
<th>Class</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>GZIPInputStream</td>
<td>Class</td>
<td>An input stream filter for reading compressed data in the GZIP file format</td>
</tr>
<tr>
<td>2.</td>
<td>GZIPOutputStream</td>
<td>Class</td>
<td>An output stream filter for writing compressed data in the GZIP file format</td>
</tr>
</tbody>
</table>

Table 22. Classes for Object Compression.

```java
// write to GZipMission object to gzipped file
import java.io.*;
import java.util.zip.*;

public class GZipSaveMission {
    public static void main(String argv[]) throws Exception {
```
// create some objects
GZipMission auv_day1 = new GZipMission("23 Mar 2004", 1, 2);
GZipMission auv_day2 = new GZipMission("24 Mar 2004", 29, 67);

// serialize the objects auv_day1 and auv_day2
FileOutputStream fos   = new FileOutputStream("gzip_db");
GZIPOutputStream gz    = new GZIPOutputStream(fos);
ObjectOutputStream oos = new ObjectOutputStream(gz);
oos.writeObject(auv_day1);
oos.writeObject(auv_day2);
oos.flush();
oos.close();
fos.close();
}
} // main
} // GZipSaveMission

Figure 76. Object Compression code snippet.

// read from gzipped GZipMission object

import java.io.*;
import java.util.zip.*;

public class GZipReadMission {
    public static void main(String argv[]) throws Exception{
        //deserialize objects "auv1" and "auv2"
        FileInputStream fis   = new FileInputStream("gzip_db");
        GZIPInputStream gs    = new GZIPInputStream(fis);
        ObjectInputStream ois = new ObjectInputStream(gs);
        GZipMission auv1 = (GZipMission) ois.readObject();
        GZipMission auv2 = (GZipMission) ois.readObject();
        ois.close();
fis.close();
    }
} // main
} // GzipReadMission

Figure 77. Object Decompression code snippet.

3. Java Archive (JAR) Format

The JAR format is based on the standard ZIP file format but adds an optional manifest file. The java.util.jar package provides classes for reading and writing JAR files. Using the classes provided by the java.util.jar package is similar to using the
classes provided by the `java.util.zip` package shown earlier. A sample manifest file is given in Figure 78.

```manifest
Manifest-Version: 1.0
Main-Class: AMVW
Class-Path: ../lib/smack.jar ../lib/smackx.jar ../lib/xercesImpl.jar
../lib/xml-apis.jar ../lib/xmlParserAPIs.jar ../lib/xalan.jar
%JAVA_HOME%/jre/lib/ext/vecmath.jar %JAVA_HOME%/jre/lib/ext/j3dcore.jar
%JAVA_HOME%/jre/lib/ext/j3dutils.jar ../lib/dis-java-vrml.jar
../lib/Jama.jar ../lib/j3d-org.jar ../lib/xj3d-all.jar ../lib/vlc_uri.jar
../lib/js.jar ../lib/vlc_uri.jar ../lib/httpclient.jar
max-heap-size: 256m
```

Figure 78. Sample Manifest.mf file for Java Archive.

### 4. Checksums

Checksums can be used to mask corrupted files or messages. Once a compressed file has been transferred to the remote machine, the checksum value can be used to detect whether the file was corrupted during the transmission.

The `Adler32` and `CRC32` classes in the `java.util.zip` package, which implement the `java.util.zip.Checksum` interface, are used to compute the checksums required for data compression. The `Adler32` algorithm is normally preferred as it faster than the `CRC32` and it is as reliable. The `getValue()` and `reset()` methods are provided to access the current checksum value or reset it to the default.

<table>
<thead>
<tr>

C. BINARY TO TEXT ENCODING AND DECODING

Embedding the byte values from the binary data file into an XML document will not work due to the XML specification's valid-character restriction and character encoding and decoding as the document travels from its source to its parsing destination.

According to the XML 1.0 specification, valid character values include the following ranges of hexadecimal values: 0x9, 0xA, 0xD, 0x20-0xd7ff, 0xe000-0xfffd, and 0x10000-0x10ffff. The specification also states that all processors are required to automatically support (and detect) the UTF-8 and UTF-16 encodings. Therefore if one of these two encodings is used when serializing XML documents, there is no need for an XML declaration (unless you need to specify version or standalone information):

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!-- the text 'encoding="UTF-8"' is optional -->
```

The ISO/IEC 10646 standard published in 1993 by the International Standards Organization (ISO) specifies the encoding of characters used to convert every written language into binary form to provide compatibility between multilingual encodings and most existing software applications that use the ASCII standard. The ISO has defined many transformations including the UTF-8 and UTF-16 encodings.

1. Brute-Force Approach

The direct approach to solving this encoding problem converts each binary data byte into its two-character hexadecimal representation. In doing so, the 256 possible byte values are encoded using two characters from the hexadecimal character set “0-9”, “A-F”:

```java
byte[] buffer = readFile(filename);
int readBytes = buffer.length;
StringBuffer hexData = new StringBuffer();
for (int i=0; i < readBytes; i++) {
    hexData.append(padHexString (Integer.toHexString(0xff & buffer[i])));
}
```

A `StringBuffer` rather than plain `String` concatenation is used to build the binary buffer's resulting character representation in order to avoid the unnecessary cost of repeatedly creating and then releasing `String` class instances. A possible way to accelerate the conversion is to use a hexadecimal number lookup table as shown below:
With this approach, for each byte in the original binary file, two characters are generated in the resulting XML document. Algorithmically, this approach is reasonably efficient. One of the disadvantages of this approach is that it wastes network bandwidth, which is an important consideration when transferring large binary data files.

2. **Base-64 Encoding Approach**

The next approach is the Base-64 encoding conversion. Developers have historically used this approach to encode binary data within mail messages before transporting them through mail servers that allow relatively short lines of 7-bit data units.

The Base-64 encoding algorithms is described in Request for Comments (RFC) 2045 - Multipurpose Internet Mail Extensions (MIME). To encode the data, each 3-byte sequence parcels into four 6-bit numbers. Each 6-bit number is then replaced by the corresponding US-ASCII character in the Base-64 alphabet to represent binary data and character ‘=’ for padding (i.e., byte stream's last one or two byte portions). The character set is “A-Z, a-z, 0-9, +, and /”. Carriage Return Line Feed (CRLF) characters are inserted into the output stream to keep the line lengths less than 76 characters, this line length restriction does not apply when transmitting binary data as part of an XML document.

![Figure 79. Base-64 encoding illustrated 3-byte stream converted to four 6-bit data units.](image)
The advantage of this approach over the brute force method is that it encodes three data bytes using four characters resulting in an encoded document that is only 33 percent larger than the original binary document rather than 100 percent longer using the previous method. Compared to the previous approach, 1.33 characters per byte are generated instead of two characters per byte.

Another advantage of Base-64 is that it has been widely used and many implementations are available freely. As an example, this thesis uses the already available class org.apache.soap.encoding.soapenc.Base64 in the Apache SOAP 2.3.1 implementation. In terms of conversion performance, the approach is fast since it consists of binary shift and table lookup operations. A sample base-64 encoded document is given below. The base-64 encoded content is stored in the CDATA section of the XML document.

### 3. Complex and Proprietary Algorithms

For more efficient binary to text encoding, complex algorithms such as Huffman can be employed. At the same time, it is possible to treat binary to text encoding as a form of encryption through the use of a complex and proprietary encoding scheme. Similarly encryption algorithms can be introduced during the compression process. Thus, receiving clients will require a proper implementation of the encoding algorithm to
decode the binary data from the XML messages necessitating the deployment of dedicated clients or libraries. This also brings into play the issues of software updates, correct implementation/program invocation and efficient deployment of new versions. This is opposed to Base-64 encoding, which is well-known and easily implemented.

In the article “Transfer binary data in an XML document” [Pentakalos 2001], the author implemented a simple Huffman encoding algorithm that uses the binary data set statistical properties to compress the encoded character stream. For many data sets, if a histogram is constructed for each byte value's occurrence frequency within the data set, an uneven distribution can be observed, where some bytes are used frequently while others rarely or not at all.

A properly customized Huffman coding can take advantage of this statistical property to reduce the average code length. Most frequently used bytes are represented in single characters or short character sequences, and the least frequently used with longer character sequences. For cases where the distribution is highly skewed towards a byte value subset, this encoding approach is effective, but it is not as effective for cases where the distribution is fairly uniform.

D. MESSAGING PROTOCOLS

1. Simple Mail Transfer Protocol (SMTP)

The objective of Simple Mail Transfer Protocol (SMTP) is to transfer mail reliably and efficiently. SMTP is independent of the particular transmission subsystem and requires only a reliably ordered data-stream channel. Mail via SMTP is a widely supported capability that can be used for messaging across firewalls.

An important feature of SMTP is its capability to relay mail across transport service environments. A transport service provides an inter-process communication environment (IPCE) that may cover one network, several networks, or a subset of a network. It is important to realize that IPCEs do not have a one-to-one relationship with networks. A process can communicate directly with another process through any mutually known IPCE. Email is one example of an application relying on IPCEs. Mail can be communicated between processes in different IPCEs by relaying through a process.
connected to two (or more) IPCEs. More specifically, mail can be relayed between hosts on different transport systems by a host on both transport systems.

2. File Transfer Protocol (FTP) and Secure FTP (SFTP)

The objectives of FTP are 1) to promote sharing of files, 2) to encourage indirect or implicit (via programs) use of remote computers, 3) to shield a user from variations in file storage systems among hosts, and 4) to transfer data reliably and efficiently. FTP, though usable directly by a user at a terminal, is designed mainly for use by programs. The FTP specification attempts to satisfy the diverse needs of users of maxi-hosts, mini-hosts and personal workstations, with a simple and easily implemented protocol design.

Files being transferred by FTP are vulnerable to man-in-the-middle attacks where data is intercepted and altered before sending it on its way. Various products have been developed to resolve the security problems with FTP. Some SFTP products use Secure Socket Layer (SSL) algorithm to perform the encryption, however, worth noting is that this approach should not be confused with the common use of SSL for browser-based file transfer encryptions. SSL by itself is limited in its capabilities. FTP and SFTP allow users to change directories, list directories, and grab entire batches and directories of files in one fell swoop. SSL is generally used for getting files, and is rather limited when used for putting batches of raw files in remote locations. While SSL is well-suited for short online web-based financial transactions, since it requires no special client-side software except a browser, it is not appropriate for large-scale batch file transfers due to the high computation costs (and correspondingly long delay times) of encryption/decryption.

3. HyperText Transport Protocol (HTTP) Get/Post and Secure Hypertext Transfer Protocol (HTTPS)

Currently, HTML forms allow the producer of the form to obtain information from users. These forms have proven useful in a wide variety of applications in which user input is necessary, however, this capability is limited because HTML forms do not provide a way to ask the user to submit files of data. Service providers requiring files from the user have had to implement custom user applications. Since file upload is a feature that will benefit many applications, this thesis proposes an extension to HTML to
allow information providers to express file upload requests uniformly, and a MIME compatible representation for file upload responses. Also included is a description of a backward compatibility strategy that allows new servers to interact with the current HTML user agents.

HTTPS is a secure message-oriented communications protocol designed for use in conjunction with HTTP. HTTPS is designed to coexist with HTTP's messaging model and to be easily integrated with HTTP applications. Syntactically, Secure HTTP (HTTPS or S-HTTP) messages are the same as HTTP, consisting of a request or status line followed by a header and body. However, the range of headers is different and the bodies are typically cryptographically enhanced. HTTPS messages, just as the HTTP messages, consist of requests from client to server and responses from server to client.

HTTPS does not require client-side public key certificates (or public keys), as it supports symmetric key-only operation modes. This is significant because it means that spontaneous private transactions can occur without requiring individual users to have an established public key. URLs that begin with 'https' are handled using the SSL algorithm (now commonly termed as Transport Level Security - TLS) that sets up a secure, encrypted link between a Web browser and a Web server. SSL is the industry standard protocol for secure, web-based communications and transactions and is implemented as an optional protocol layer that fits between the TCP and HTTP protocol layers.

4. Messaging Queue System (e.g., Java Messaging Service)

The Java Message Service (JMS) API is an API for accessing enterprise messaging systems. It is part of the Java 2 Platform, Enterprise Edition (J2EE).

JMS is designed to make it easy to write business applications that asynchronously send and receive critical business data and events. It defines a common enterprise messaging API that can be easily and efficiently supported by a wide range of enterprise messaging products. JMS supports both message-queuing and publish-subscribe styles of messaging.

JMS messages are asynchronous requests, reports, or events that are consumed by enterprise applications, not humans. They contain vital information needed to coordinate
these systems and contain precisely formatted data describing specific business actions. Through the exchange of these messages, each application tracks the progress of the enterprise.

Jabber is a set of streaming XML protocols and technologies that enable any two entities on the Internet to exchange messages, presence, and other structured information in near-real time. Jabber is an open, platform independent messaging framework based on XML for real-time extensible messaging and user presence. The basic Jabber application is an instant messaging (IM) network that offers functionality similar to legacy IM services such as AIM, ICQ, MSN, and Yahoo. However, Jabber is more than just IM, and Jabber technologies offer several key advantages. The Internet Engineering Task Force (IETF) is currently formalizing the core XML streaming protocols as an approved instant messaging and presence technology under the name of XMPP. The following sections explore the use of Jabber protocol for both human and machine message passing such as agent-to-agent communications.

</tbody>
</table>

Table 24. Comparison of messaging systems and their protocols.
E. MESSAGE REPRESENTATION

Traditional messaging systems (e.g., email) store binary data as an attachment to the message subject/body. With XMPP, all messages are XML-based making it necessary to find ways to send binary data via this protocol. The XMPP protocol includes a base protocol and many optional extensions typically documented as Jabber Enhancement Proposals (JEPs).

1. Jabber Enhancement Proposals
   
a. Private Data (JEP-49)

   JEP-49 is a mechanism to allow users to store arbitrary XML data on an XMPP server. Each private data chunk is defined by an element name and XML namespace. Example private data:

   ```xml
   <color xmlns="http://example.com/xmpp/color">
     <favorite>blue</favorite>
     <leastFavorite>puce</leastFavorite>
   </color>
   ```

   A Jabber client can store any arbitrary XML on the server side by sending an `iq` chunk of type "set" to the server with a `query` child scoped by the `jabber:iq:private` namespace. The `query` element may contain any arbitrary XML fragment as long as the root element of that fragment is scoped by its own namespace. The data can then be retrieved by sending an `iq` of type "get" with a `query` child scoped by the `jabber:iq:private` namespace, which in turn contains a child element scoped by the namespace used for storage of that fragment. Using this method, Jabber entities can store private data on the server and retrieve it whenever necessary. The data stored might be anything, as long as it is valid XML. One typical usage for this namespace is the server-side storage of client preferences.

b. Extensible HyperText Markup Language (XHTML) (JEP-71)

   The JEP-71 proposal defines an adaptation of XHTML 1.0 to provide alternative formatting for a text message. It provides the ability to send and receive formatted messages using XHTML. This pattern is familiar from email, wherein the HTML-formatted version of the message supplements, but does not supersede the text-only version of the message. In Jabber communications, the meaning (as opposed to formatting) of the message must always be represented as best as possible in the normal
body child of the message element. Formatting is then provided by the XHTML representation of the message content within a html wrapper element.

These two JEPs provide two possible ways to package binary data:

- Embed a hyperlink to binary data via out-of-band (oob) messages.
- Embed the binary data in a CDATA section.

Even though these two methods could be used to represent binary data, one is not necessarily a good substitute for another. Alternatively, these methods can be applied to complement each other.

An out-of-band message is a message x extension that is embedded in a standard Jabber message packet (usually a message of type normal). An oob message contains information, typically a url link that clients can use to conduct direct application-to-application data transfer that bypasses the normal Jabber message routing via the Jabber server. The link typically points to a web or FTP server.
Out-of-band messages are typically used to arrange transfer of large files that are impractical to route via the server. A sample *oob* message is given below:

```xml
<iq type='set' id='file_1' to='recipient@surfari.cs.nps.mil/home'>
  <query xmlns='jabber:iq:oob'>
    <desc>Here is the image file you requested.</desc>
    <url>http://files.nps.mil/sample.bmp</url>
  </query>
</iq>
```

Although this method reduces network traffic on the Jabber server (note: actual traffic required to transport the binary data from one location to another is still the same), it introduces a point of failure to the transport mechanism; if the storage server is offline, there is no way to retrieve the data. This problem can be circumvented through the introduction of multiple hyperlinks to the same binary data; i.e., each hyperlink pointing to different storage locations of the same file.

```xml
<iq type='set' id='file_1' to='recipient@surfari.cs.nps.mil/home'>
  <query xmlns='jabber:iq:oob'>
    <desc>Here is the image file you requested.</desc>
    <url>http://fileserver1.nps.mil/sample.bmp</url>
    <url>http://fileserver2.nps.mil/sample.bmp</url>
    <url>http://fileserver3.nps.mil/sample.bmp</url>
  </query>
</iq>
```
3. **Embed Binary Data in \textit{CDATA} Section**

In order to reduce the time required to retrieve data from another location, binary data can be embedded within the XML document. This allows the recipient to process the data immediately upon receipt. By making use of compression and base-64 encoding techniques discussed earlier, it is possible to reduce the size and at the same time embed binary data in an XML message. To add another layer of reliability to this method, multiple hyperlinks to storage locations are added. This is similar to the technique discussed above. If the encoded/compressed data was corrupted during its delivery, the recipient will still be able to retrieve it from a storage server via FTP or HTTP. (Note: Since some firewalls block out FTP traffic, therefore it is better to include links to both FTP and HTTP servers.) At the same time, a maximum file size limit can be introduced to prevent overloading the Jabber server. Thus for a large file (e.g., larger than 1MB), the \textit{CDATA} section will not be populated with the encoded binary data, and hyperlinks will be used to retrieve the file. Upon receipt, the client spawns an HTTP or FTP process to retrieve the file from the storage location. A sample XML message (without the Jabber message wrapper) and the function to perform base-64 encoding and compression are given Appendix E.

```xml
<AgentJabber>
  <!--Payload 1-->
  <AgentPayload checksum="1234567" content-transfer-encoding="base-64" content-type="application/x-zip-compressed" desc="The filename is [GAMMA.bmp]" filename="GAMMA_apple.bmp" filesize="48586" timestamp="2004026114827">

F. DESIGN AND IMPLEMENTATION

1. Overview

This section explores possible ways to implement chat clients that enable the data exchange of both messages and binary files using Jabber protocol. The three approaches covered in this section are: web-based, standard client and customized Jabber client. This section discusses how an application that makes use of Jabber protocol for communications can be implemented. Technical details on the use of compression and base-64 encoding to facilitate message exchange of both textual (e.g., mission scripts) and non-textual (e.g., images) data are also covered.
2. Introduction to Jabber Protocol

A full Jabber ID takes the form [user name]@[Jabber server]/[resource], similar to an email address. A groupchat/chat room takes the form: [chatroom/group name]@[Jabber groupchat server]/[nickname]. There are three core Jabber protocols, namely:

- **Message.** This is responsible for the delivering of data. Most of the time, it accounts for the bulk of the packet traffic on the Jabber network. These messages can resemble full-scale email messages or form line-by-line messages in chat sessions. This protocol uses the message packet. A sample message packet is given below:

```xml
<message xml:lang="en-us" to="savage@conference.xchat.movesinstitute.org" type="groupchat">
  <body>This is a test message</body>
</message>
```

Figure 85. A sample “groupchat” message to “savage” chatroom.

</tr>
<tr>
<td>6.</td>
<td>body</td>
<td>Element</td>
<td>Message body.</td>
</tr>
</tbody>
</table>

Table 26. Message packet types and protocol.

- **Presence.** The basic presence protocol is used in presence update and presence subscription management. Presence update is to inform people of the user’s current presence state. Presences subscription management allows people to subscribe to another user’s presence update packet and control who has access to their own presence. This protocol uses the presence packet. A sample presence packet is given below:

```xml
<presence from="auvrobot@surfaris.cs.nps.navy.mil"
to="savage@conference.xchat.movesinstitute.org"
type="available">  
  <status>I am now logged on to chatroom.</status>  
  <priority>10</priority>  
  <show>chat</show> 
</presence>
```

<td>show</td>
<td>Element</td>
<td>Jabber clients typically use this to display presence icons, sound or alerts. If no show state is indicated, the user is in normal or online state. The other possible states are chat, away, xa (extended away) and dnd (do not disturb).</td>
</tr>
</tbody>
</table>

Table 27. “Presence” packet types and protocol.

- Info/Query (IQ). This handles everything else that does not fall under a Message or Presence packet. It serves as a catch-all protocol. If a protocol is not sending a message, or managing presence, it is an IQ protocol. IQ is a generic request-response protocol and it is designed to be easily extensible with IQ extension protocols. An IQ packet may look like the following:

```xml
<iq type='get' to='handlerJID'>
  <query xmlns='jabber:iq-auth'>
    <username>auvcontrol</username>
  </query>
</iq>
```

A typical Jabber session:

- Connect with a Jabber server (e.g., xchat.moveinstitute.org).
- Open a Jabber stream by logging in using user account “auvcontrol”, password “auvpwd” on domain “xchat.moveinstitute.org”.
- Update presence status to “available”.

100
3. **Web-based Jabber Client**

The components required for this approach are a HTML form running on the client’s Internet browser and a Java servlet on the web server to process, package and send out the Jabber messages. An HTML form can be easily implemented using standard HTML objects. Below are some examples of HTML objects used to generate the HTML form:

```html
<!-- Creates a single-line text entry control -->
<input type="text" name="edtSubject" value="Message Subject" size="30">

<!-- Creates a file upload object with a text box and Browse button. -->
<input type="file" name="edtFile">
```

For a file upload to take place:

- The `INPUT type=file` element must be enclosed within a `FORM` element.
- A value must be specified for the `NAME` attribute of the `INPUT type=file` element.
- The `METHOD` attribute of the `FORM` element must be set to post.
- The `ENCTYPE` attribute of the `FORM` element must be set to `multipart/form-data`.

To handle a file upload, a server-side process must be running that can handle multipart/form-data submissions. For this thesis, a Java servlet was implemented to parse and package the uploaded HTML data to be sent out as an XHTML Jabber message. The servlet uses the O’Reilly multipart file upload library (`com.oreilly.servlet`) to extract the uploaded file data.

With a HTML form, user input can be validated before it is sent to the server. If validation is performed on the client web browser, it is likely to be implemented using Netscape’s JavaScript or Microsoft’s VBScript. JavaScript syntax is different from VBScript. Since JavaScript and VBScript are specifically designed to work in browsers, they do not include features that are normally outside the scope of scripting, such as file access and printing. JavaScript is preferred for validation code due to compatibility and
consistency issues, especially VBScript on different browsers. Specifically, while VBScript is fully supported by Microsoft Internet Explorer, the same cannot be said for other browsers.

At the time of this thesis, a “send-only” HTML form has been developed. Therefore the user will still require a Jabber client to view incoming Jabber messages. A possible way to implement a message receive module in the Internet browser is as follows.

- Modify the servlet to listen for incoming messages from one or more chat-rooms or JIDs.
- Upon receipt of Jabber messages, convert them to HTML format (include date/time for easy reference). This is to be displayed within a HTML frame on the client Internet browser.
- HTML is for display purposes, it does not have the means to actively listen for updated web pages. Thus a simple polling mechanism is required. This example causes the browser to reload the document every five seconds, but it causes unnecessary refresh on the web page.

Steps involved in sending a message via the web-based Jabber approach:

<table>
<thead>
<tr>
<th>Client:</th>
<th>Server:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access to Jabber-enabled website using standard Internet browser.</td>
<td>Servlet receives posted HTML data and files, if any.</td>
</tr>
<tr>
<td>Key-in required data in the HTML Form.</td>
<td>Re-package HTML data to XHTML Jabber format.</td>
</tr>
<tr>
<td></td>
<td>Get list of recipients from configuration file.</td>
</tr>
<tr>
<td></td>
<td>Log into Jabber server.</td>
</tr>
<tr>
<td></td>
<td>Send packaged data as Jabber message to recipients.</td>
</tr>
</tbody>
</table>
Figure 88. Data and file transfer via HTTP-Jabber protocol.

Figure 89. Sample HTML form for posting of data.
4. **Standard Jabber Client**

Standard Jabber clients are only able to send and receive standard Jabber messages (subject and message body). Certain clients (e.g., Rhymbox) have a “Console” interface that allows the user to key-in and send customized Jabber messages, however the files still need to be compressed, binary-to-text encoded and packaged as XHTML format before they can be sent out. The user needs to manually invoke the modules (if
any) that will perform the conversion, copy-and-paste the textual results into the “Console” interface and then send it out. This process is tedious and diminishes the usability of this technique of message exchange, especially when the load increases.

Steps involved in sending a message via the standard Jabber client approach:

<table>
<thead>
<tr>
<th>Client:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Log into Jabber server.</td>
</tr>
<tr>
<td>• Key-in message subject and body.</td>
</tr>
<tr>
<td>• Send to specific user IDs or chat-rooms.</td>
</tr>
</tbody>
</table>

Figure 92. Rhymbox Jabber client.
5. Customized Jabber Client

A customized Jabber client can send and receive standard Jabber messages as well as messages with embedded binary data. The customized client automatically packages and sends out XHTML messages. It is also able to mimic an Internet browser and perform a HTTP POST of data and files to a Jabber-enabled web site (i.e., deployed with the servlet to receive posted data and files). This ability has been incorporated in the customized Jabber client for this thesis.

Of the three proposed solutions, only the customized client is able to re-generate the binary data either by decompressing and decoding the embedded data, or by retrieving the file from a hyperlink (specified within url tags). Once the data has been re-generated, it invokes the module or application to display the data.

The third approach functions both as a backup for Jabber communications and as a storage location for binary data that is referenced (in url tags) in the Jabber XHTML messages. Although the customized Jabber client is the most complex and takes the longest to develop, it is the most flexible solution. To enable reuse, the customized client that has been developed for this thesis is generic. Therefore it can be plugged into any application for that requires text and binary data message passing.
Figure 94. Customized Jabber client user interface to send data and files as Jabber message.

Figure 95. Customized Jabber client user interface to display list of incoming Jabber messages.
The following table provides an overview of the three techniques discussed. For this thesis, emphasis was placed on the customized client due to the need to integrate into the AUV Workbench. The web-based solution using HTML form is also a viable solution provided there is a way to perform “smart” refresh of posted messages.
Table 28. Comparison of the three approaches.

6. Interior of a Jabber-enabled Agent

This section provides an overview of how the different pieces of technologies are put together, using agents as an exemplar. Each agent makes use of its own unique Jabber ID to identify itself within the Jabber network. There are two ways whereby the agents can communicate. Peer-to-peer “chat” messages are used for dedicated agent-to-agent
communication; whereas “groupchat” messages are used to allow multiple agents to listen to and react to messages posted on the chatroom. The “groupchat” feature is similar to a “publish-subscribe” mechanism.

Once the binary data has been extracted, it can be worked on by other processes or saved in a database for archival purposes. Components of the agent interior are shown in Figure 98 and described below.

![Figure 98. Interior of a Jabber-enabled agent.](image)

**a. Jabber Communications**

This handles network communications for the Jabber protocol such as login, joining chatrooms, initiating chat sessions and listening for messages.

**b. Message Formatting**

Packaging of the message header and its payload is done in this module. The message payload includes message subject, body and binary data, if any. This module is responsible for packaging one or multiple files within the same Jabber message. An example with two files is show in Figure 99.
c. **Message Processing**

The message generation process is done prior to sending. Upon receipt, processes such as archival into database or flat file can be triggered, in addition to invocation of programs to display the binary data; e.g., JPEG and GIF images. This module determines whether the binary data will be embedded in the message. This is based on a predetermined file size (e.g., 1MB). This prevents overloading the Jabber servers and in addition, certain administrators limit the message size. Therefore it is advisable to send small-sized files via the Jabber protocol. The file data is only stored within the CDATA section provided its size is less than the preset limit. Otherwise the CDATA is left empty (See Figure 100), but the header information pertaining to the file, such as file name and size, are kept in the message payload.
Upon receipt of a message, this module determines whether it needs to retrieve from binary data from a hyperlink (i.e., if \textit{CDATA} section is empty). Storage locations of the binary data file may reside on a web server (e.g., Apache Tomcat), FTP server or a dedicated agent with web server functionalities built into it. With an Apache web-server, it needs to be administered. On the other hand, having web server functionalities reside in a Jabber-enabled agent reduces the need for additional administration. It may not be advisable, however to burden the agent with additional processes.

Pre-processing activities that are platform or system specific; e.g., image segmentation on UAV imagery, are not included as part of the message processing module. This keeps this module generic and thus extensible to other AUV or non-AUV platforms, as well as improving the performance of the module. Pre-processing modules are responsible for computation of data, representation (e.g., how to capture continuous changing information such as change in water pressure due to an explosion), and generation of results in file or text format.

\textbf{d. Compression and Decompression}

Compression of the message packet to reduce its size is done here. Similarly, decompression is performed at the receiving end. Some file formats are already in compressed form; e.g., GIF, JPEG and PNG do not require further compression. Compress-able file formats include Windows bitmaps and ASCII text. If
the zipped form of the file is bigger than the original file size, the original data file is used instead. For this thesis, standard compression and decompression from Java are used. For added security, this module can be easily replaced with a cryptographic module here and on the receiving end.

**e. Base-64 Encode and Decode**

Binary to text encoding is performed in this module to handle non-textual data; e.g., images, audio, video and compressed data from the compression module.

**f. XML Parsing**

Since Jabber messages are XML-based, XML parsing and transformation are required. Open-source libraries (Apache Xerces for parsing, Apache Xalan for transformation) are used.

### 7. Message Generation

The steps to process an outgoing message are given below.

1. Loop through list of files to be sent.
2. For each file, do the following:
   a. Create a `<agent-payload>` element.
   b. Add file information such as name, size and content-type into the `<agent-payload>` attributes.
   c. Determine file types based on file extension (e.g., .BMP is 24-bit Windows bitmap and .GIF is Compuserve GIF).
   d. If the files types are GIF, JPEG, EXE, do not compress. Otherwise, perform compression. If compressed data size is greater than original, encode the original data instead.
   e. Check whether the file size exceeds a predefined limit. If no, proceed to compress and encode into CDATA section of message.
   f. If available, always add a list of hyperlinks associated to the file under the `<url>` tags.
3. Generate XHTML message.
4. Append to the XHTML portion of Jabber message and send it out to designated parties.
The steps to process an incoming message are given below.

1. Loop through list of `<agent-payload>` elements.
2. For each `<agent-payload>` element, do the following:
   a. Get file information such as name, size, content-type and content-transfer-encoding.
   b. Check whether there is data in the `CDATA` section of message.
      i. If yes, check type
      ii. Otherwise, loop through the list of `<url>` tags and try to retrieve the file from one of the storage locations specified within the `<url>` tag. At the moment, the customize client is able to fetch the file from a web/HTTP server and local/networked file system.
   c. Upon successful retrieval of the file contents, an “AgentPayload” object shall be created.

```
<agent-payload ...>
  <url>http://server2/Cheshire Cat.svg</url>
  <url>http://server3/Cheshire Cat.svg</url>
  <url>ftp://www.server3.com/Cheshire Cat.svg</url>
  <url>file://c://server3/Cheshire Cat.svg</url>
  <url>c://server3/Cheshire Cat.svg</url>
</agent-payload>
```

Figure 101. Links to multiple storage locations.

Figure 102. Processing of outgoing binary file data before it is sent out via Jabber protocol.
8. Smack Library

Smack is a library for communicating with XMPP servers to perform instant messaging and chat. The library provides easy machine-to-machine communication and it allows the setting of any number of properties on each message, including properties that are Java objects. The library was developed and maintained by Jive Software, at www.jivesoftware.com (accessed February 2004) and is open-source under the Apache Software License, which allows its incorporation into both commercial and non-commercial applications.

The library is extremely simple to use, yet it has a powerful set of Application Programming Interfaces (APIs). Sending a text message to a user can be accomplished in three lines of code:

```java
XMPPConnection connection = new XMPPConnection("surfaris.cs.nps.navy.mil");
connection.login("userA", "passwordA");
connection.createChat("userB@xchat.movesinstitute.org").sendMessage("Hello");
```
Smack provides the `org.jivesoftware.smack` package for the core XMPP protocol, and the `org.jivesoftware.smackx` package for many of the protocol extensions.

G. BENCHMARKS

In the benchmark tests, only the timings for packaging (i.e., compression and base-64 encoding) are captured. Network timings (i.e., Jabber instant messaging) are excluded since the results will be subjected to the network traffic and the available bandwidth. The ASCII plain-text data are from GEOnet Names Server (GNS) at [http://earth-info.nima.mil/gns/html](http://earth-info.nima.mil/gns/html) (accessed on 15 February 2004). The XML plain-text data were converted from the ASCII data using the GNS class (see Appendix F). A sample procedure to convert GNS plain-text data to XML format is given below.

### H. SUMMARY

This chapter has proposed a solution to package text and binary data to be sent via Jabber instant messaging protocol. Compression of data was done using standard Java classes. The Java classes compressed both text-based (including XML-based file) and binary files such as images. In general the percentage of compression achieved is 75% of the original file, higher for text-based files. As for Windows bitmap images, the compression ratio depends on the type of image that has been stored. Therefore a better way to ensure optimal compression is to convert the Windows bitmap images to PNG or JPEG format on the fly. Of note, JPEG is lossy and may cause degradation in image quality. Therefore PNG format is favored for its lossless’ nature. To achieve better compression ratio for XML data, XML Schema-based Binary Compression (XSBC) (Serin2003) can be used to complement the Java classes. XML files are handled by XSBC, whereas non-XML files such as plain-text or images are handled by the proposed
mechanism. Forward Error Correction can be introduced to ensure reliability of data transmission and receipt over noisy communication channels.

On average, the base-64 encoding of the binary data to text data, for storage in the CDATA section of the Jabber XML-based message, increased the file size by 33%. A better binary to text encoding scheme (e.g., using Huffman algorithm), can be pursued in future work.

It is important to note that besides size, the time taken to run the compression process also plays an important part. An algorithm may be good at generating a smaller sized file, but the time taken may be so long that it is unacceptable to the user.

There is a physical message size limit set on the Jabber server. This is to prevent overloading the Jabber server. Although the proposed mechanism introduces the use of hyperlinks to circumvent the potential issues, a more robust solution should be pursued; e.g., if the size is too big, the file is automatically posted on a web server using standard HTTP POST mechanism.
V. TASK COLLABORATION USING AGENTS

A. INTRODUCTION

Multiple vehicles operating in a coordinated manner can be more effective than a single one. For instance, a cluster of coordinated Autonomous Underwater Vehicles (AUVs) can search a coastal area for mines more effectively than a single vehicle, however handling unanticipated events (novel or completely unexpected) is difficult, since they are sometimes hard to detect, much less diagnose and respond to, even for a single vehicle. If the AUV is part of a cooperative or collaborative distributed multi-agent system, the problem is compounded. The AUV controller must now be concerned about what the event means for the others, the group as a whole, and their shared mission/goal. Multi-agent event handling is complicated by uncertainty and lack of knowledge about other agents’ intentions/goals; it is exacerbated by the low bandwidth of communication channels available for use in the ocean.

An agent also needs to be able to communicate with other agents to fill in the gaps in its models or hypotheses, to establish mutual beliefs and confirm expectations, and to negotiate responsibility for the different tasks during event handling. Some key challenges include:

a. To determine an efficient way to deploy multiple Autonomous Underwater Vehicles (AUV) for collaborative work such as mine counter-measures missions.

b. To determine what is the optimal number of AUVs to be used for a scenario (e.g., based of time of completion).

c. To investigate amount of deviation between real-world dynamics and simulated ones in a virtual environment.

d. Ability to play out more scenarios at less cost compared to live sea-trials.

This chapter discusses the potential use and design of AUV agents.
Following the MAS = \{Environment, Objects, Agents, Relationships, Operations, Laws\} approach [Ferber 1999], the various components of the system are discussed in the following sections.

**B. ENVIRONMENT**

The AUVs operates in the ocean (sub-surface). The area of operation is determined by the physical constraints of the AUV, as depicted below:

a. **Endurance.** The fuel tank size of the AUV is fixed.

b. **Speed.** The maximum speed of the AUV is fixed.

c. **Sensor.**

d. **Communications.**

For purposes of simulation, there is a finite number of AUVs, maximum five. Similarly the maximum number of Communications Stations (include land, air and sea-based) is set to five. The need to limit the number of AUVs and Communications Stations is to better model the real-world environment, where it is impossible to have an infinite number of resources. For the experimental runs, it is possible that zero or more obstacles may be placed in the environment.

6. Launching/Pick-up Point

The position where the AUV is launched and picked up upon completion of goals or when out of fuel/time.

D. AGENTS AND ACTORS

The presence of multiple agents impact event handling in several ways. First, an agent may notice an event that does not directly concern it, but impacts another agent. In this case, the detecting agent can consider notifying the other agent about it. Second, there is the possibility that multiple agents detect the same event simultaneously. If this happens, the agents must coordinate their event-handling activities to avoid confusion and counter-productive work. Third, other agents can serve as a source of information (solicited or otherwise). Some agents may be in a better position with respect to the knowledge they have or can easily obtain to do diagnosis or important assessment, and others may be better situated to carry out the responses. At the very least, a detecting
agent notifies the affected agents of actions it is taking, whether in service, diagnosis, or in response to an event. Figure 112 illustrates the relationships between inputs/outputs and the agent interior.

*Table 34. Agent input and actuator suite.*

Each AUV agent has the following attributes/states stored in the “brain” of the agent. The agent interior is hidden from other agents unless the information is exposed via the agent’s output or actuator suite.

- Endurance. Elapsed time is computed at the start of the experiment based on the amount of fuel available.
- List of obstacles encountered. Obstacles include mines, marine life and other AUVs.
- Mission scripts of AUV commands. List of waypoints and the corresponding arrival/departure time at each waypoint. To improve
interaction between both AUVWorkbench and other applications, the
mission scripts/commands are defined in XML format (see sample
Mission Script below).

```xml
<?xml version="1.0" encoding="UTF-8"?>
<AUVMissions xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="C:/AUVWorkbench/bin/scripts/missionScripts/AUVMission.xsd">

Table 35. Mission script XML tag set.
The same mission plan is loaded into all the AUVs. The course of action is negotiated between the AUV agents. Each AUV is able to determine its location based on its heading, speed and time elapsed (with reference to the start point). When a Communications Station is within the AUV’s transmission range, the agent polls the station for its position. Using the coordinates returned by the Communications Station and distance between the Communications Station and AUV, the agent tries to check whether its internally computed position is correct. Here is how the goals are defined:

<table>
<thead>
<tr>

<td>Communications</td>
<td>Transmission of data back to comms stations.</td>
<td>-</td>
</tr>
</tbody>
</table>

Table 36. Agent goal definition.

For each of the goals defined, there is a priority (similar to “traffic-light” system) assigned to them. The priority shall have three states – low, medium and high.

### E. RELATIONSHIPS

1. Define initial goals and update status as required (Mission Plan ↔ AUV).
2. Encounter or detect an obstacle (Obstacle → AUV).
4. Transmit findings to Communications Stations or receive positional data/new orders (Communication Stations ↔ AUV).

### F. PROCESSES AND OPERATIONS

1. Follow waypoints defined in Mission Plan.
2. Compute its position internally based on its speed and elapsed time.
3. Update “waypoint reached” status upon arriving or bypassing a waypoint.
4. Upon obstacle detection or encounter, look for closest AUV agent and/or Communications Stations to share information.
5. When within range of another AUVs, share the following information; 1) own percentage of Mission Plan completion; 2) own position.

6. When within range of Communications Station, the AUV checks whether its own computed position is correct by referencing the Communications Station’s position (pre-loaded into AUV). If not, perform compensatory action. In addition, it checks whether the list of waypoints that it thought it passed is correct.

G. SUMMARY OF LAWS

1. Communications between AUV-AUV and AUV-Communication Stations are possible only when within range. This is a “Many-to-Many” relationship.

2. Communications shall be initiated by the AUV or Communications Stations.

3. Communications Stations are manned or remotely operated by humans. Therefore their locations are always precise since additional equipment is available to geo-reference them (GPS-enabled). All Communications Stations’ coordinates are pre-loaded or made known to AUV agents.

4. To simplify the system, there are two types of sensors, namely sonar and optics. Both types of sensors shall operate ideally with the given range and coverage. In the real-world, these sensors rarely operate to their optimal performance due to oceanic conditions.

5. The launching point and the retrieval point of the AUV may differ.

6. The team of vehicles is moving in an environment of known dimensions, searching for target of interest. The vehicles are assumed to be equipped with: 1) target sensing capabilities for obtaining a limited view of the environment; 2) wireless communication capabilities for exchanging information and cooperating with one another; and 3) computing capabilities for processing the incoming sensor data and making dynamic guidance decisions.

7. For each AUV agent, there is only one Mission Plan.
8. Fuel consumption by the AUV is constant; therefore the AUV is able to operate for a fixed time period; e.g., 3 hours.

9. The agents are equipped with sensors to view a limited region of the environment they are visiting, and are able to communicate with one another to enable cooperation. The agents are assumed to have some “physical” limitations including maneuverability limitations, fuel/time constraints and sensor range and accuracy.

H. AGENT IMPLEMENTATION

1. Concept of Connector-Ticket Pair

Packaging and Tagging of Raw Inputs. Raw inputs from sensors (e.g., sonar or video feed) are first packaged. Packaging involves formatting the data into an agent-readable form (e.g., following a particular XML schema or template). This is followed by tagging. The tagging process is to add connectors and/or tickets to the packaged data. The connector-ticket pairs allow the data to interact with the agent’s set of connector-ticket pair of goals. Finally the tagged data is passed into agent’s space for interaction. Integration networks (IN) are formed as related (in terms of time and event) tagged data is grouped together. In addition, if double-scope blending takes place, new generic spaces can be created [Turner 2002]. With the creation of new generic spaces, the agent is in fact shaping its perception of the environment.

![Figure 113. Connector-Ticket - Packaging and Tagging.](image)

Matching tagged data. At the end of each tagged data, there are either one or many connectors that match the ones that are extended from the agent’s goals (See Figure 108). Tagged data and connectors form a ticket. When there is a match, the agent may choose to retract the fulfilled goal or trigger a new set of goals. At the moment, these actions are defined as a template within the agent. With better understanding of the
conceptual blending principles, it may be possible to get the agent to formulate new goals that will aid in its fulfillment of goals/functions.

Below is a possible scenario on how goals can be altered based on the agent’s perception of the environment and its interaction with other agents through the use of connectors and tickets.

At the start of the run, agents are given basic goals; e.g., “Move along a predefined path or an area of interest within a given time”. If the AUV sensors detect an object, the basic goals are either upgraded or replaced (i.e., retracted) by more complex ones. The complex goals may vary from getting another AUV to perform identification or confirmation of contact, or to track the object/obstacle for a predefined time period, or surface and transmit data back to communications stations.

![Connector-Ticket Matching](image)

**Figure 114. Connector-Ticket Matching.**

I. AGENT-TO-AGENT COMMUNICATIONS

1. Agent Identifier

   The system makes use of the chat/Jabber ID (e.g., XTCServlet@xchat.MovesInstitute.org) to distinguish between multiple agents across a list of networked AUV Workbench applications.

   For each workbench, there is one agent identifier. The user is able to change the agent’s identifier from within the workbench. Note: the workbench must have connectivity to a chat/Jabber server.
2. **Communications**

Extensible Messaging and Presence Protocol (XMPP) is used as the means for communications between agents. The techniques for packaging and transporting agent messages via XMPP are the same as those discussed in Chapter IV.

![Figure 115. Agent-to-agent communications using XMPP.](image1)

![Figure 116. Human and Agent interaction via Jabber chat room.](image2)

3. **Strategy for Data Collection**

- Compute number of AUVs and Communications Stations available.
- Compute the percentage of completion of Mission Plan.
- Keep track of obstacles encountered (mines and AUVs).
4. **Data Analysis**

   **a. Initialization Phase**

   The system randomly assigns a unique ID for each of the AUV agent. The mission plan is loaded into the AUVs together with start and end locations, and Communications Station locations.

   Once the Mission Plan has been loaded, the agent computes the feasibility of completing the plan, within the required time allowed (or fuel constraint). If not, it informs the user to make changes to the Mission Plan. If the plan is feasible, the agent generates an internal “Search Map”. Unvisited waypoints (in RED, Figure 117) are marked. Similarly for Start/End points (in GRAY, see Figure 117) and the locations of Communications Stations (in CYAN, see Figure 117).

   **b. Start/During the Run (AUV Execution)**

   - When a *waypoint* is reached, it is marked (in GREEN, Figure 117). The time is recorded and compared against the time specified in the Mission Plan. A tolerance of 5-10 minutes is allowed. If the time discrepancy is too great, the agent tries to compensate by increasing speed to the next waypoints.

   - When the agent senses an *obstacle*, it slows down and tries to identify what it is (e.g., by shape and size). To identify the obstacle, it instructs the vehicle to move around the obstacle to gather more data. If a particular type of obstacle (e.g., mine) has been found, it tries to inform the Communications Stations and other AUVs. And if neither an AUV nor Communications Station is within its vicinity, it proceeds to the closest Communications Stations and/or moves towards a previously known AUV’s direction. The obstacle is marked in the agent’s internal “Search Map”. Additional information on the obstacle such as size, moving/stationary and type are also captured in the corresponding grid square in the “Search Map”. 

134
When in contact with another AUV or within the transmission range of Communications Station, it shares its position, orientation, heading and speed with it. Similarly the other AUV shares the same attributes.

c. **Possible Strategies**

- **Follow the path where there is minimum overlap with other agents.** Since the agents are able to share their new information about the search region, it is natural that they may select the same search path as other agents (especially since in general they will be utilizing the same search algorithm). This will be more pronounced if two agents happen to be close to each other. However, in order to minimize the global uncertainty associated with the emergent knowledge of all agents, it is crucial that there is minimum overlap in their search efforts. This can be achieved by including a cost function component that penalizes agents being close to each other and heading in the same direction. This component of the cost function can be derived based on the relative locations and heading direction (angle) between pairs of agents. [Polycarpou 2001]

- **Follow the path that maximizes coverage of the highest priority targets.** In mission applications where the agents have a target search map with priorities assigned to detected targets, it is possible to combine the search of new targets with coverage of discovered targets by including a cost component that steers the agent towards covering high priority targets. The cost component is based on the target’s characteristics such as shape, size, mobility and its overall effect on the mission (e.g. mines have a higher priority). This leads to a coordinated search where both coverage and priorities are objectives.

- **Follow the path toward highest priority targets with most certainty.** In some applications, the energy of the agent is limited.
In such cases it is important to monitor the remaining fuel and possibly switch goals if the fuel becomes too low. For example, in search-and-engage operations, the agent may decide to abort search objectives and head towards engaging high priority targets if the remaining fuel is low. Environment factors such as sea state will also affect the operational effectiveness of the AUV sensors as well as its maneuverability.

- **Follow the path toward targets where there will be minimum overlap with other agents.** Cooperation between agents is a key issue not only in search patterns but also in engagement patterns. If an agent decides to engage a known target, there needs to be some cooperation such that no other agent tries to go after the same target; i.e., a cooperative engagement strategy is utilized. On the other hand, this strategy will depend on the availability of the weapon systems onboard the AUV. Multiple attacks will increase the cumulative probability of kill, but this has to be weighted against the probability of not having resources to search for other targets or even to react in time to another target once the AUVs are on-route to the first known target. At the same time, there is also a probability of losing the first target and reacquisition will be required before engagement can commence.
J. SUMMARY

This chapter discusses the design of the AUV agent attributes and possible strategies to define the agents’ goals. Means of communications between agents using Jabber instant messaging were presented. An example application to construct a search map is described.
VI. CONCLUSIONS AND RECOMMENDATIONS

A. INTRODUCTION

The main purpose of this work was to design and implement a common platform for AUV mission planning and analysis. The end product is the AUV Workbench. Using Java-based open-source libraries for functionality, Extensible Markup Language (XML) for data storage and exchange, and a component-based framework, the AUV Workbench provides an intuitive cross-platform-capable tool with extensibility to provide for future enhancements such as agent-based control, asynchronous reporting and communication, and loss-free message compression.

In addition, this thesis has explained the suitability of Jabber instant messaging for text and file messaging in a tactical environment. Exemplars have shown that the XML backbone of this open-standards technology can be leveraged to enable both human and agent messaging, providing powerful improvements over current systems.

B. RECOMMENDED FUTURE WORK

1. Overview

This thesis established the foundation for future work for modeling and simulation of AUVs. This work has demonstrated that the AUV Workbench provides a test-bed for emergent AUV technologies and can assist in the development of traditional and agent-based methodologies. Additionally, the flexible design of the Workbench facilitates potential extensions to serve operational needs. A list of recommendations is given in this section.
2. **AUV Multi-Agent System Framework**

Most AUV missions neither require nor permit constant human oversight. Operating conditions, adverse environmental conditions or inherent limitations of underwater communications paths can cut off communications with the vehicles. For example, a covert surveillance or reconnaissance mission precludes all but the most minimal communication with the vehicle. Therefore if a virtual AUV agent is able to simulate the real AUV in water, it is able to provide human operators with a visual or audible cue on its whereabouts. When the real AUV surfaces, the virtual AUV synchronizes its position and status (e.g., sensor data or equipment failure). While the actual AUV is in water, the human operator may re-task the AUV using AUV agent, with the re-tasked orders transmitted to the actual AUV.

Ideally, AUVs are capable of acting truly autonomously for long periods of time in challenging, unpredictable environments. As the missions undertaken by the AUV become more complex, it becomes difficult for the human to keep up, making agents potentially useful. A set of rules is given to the agents. The human operator intervenes when there is a conflict or when a critical condition arises (i.e., system failure or mine detection).
Just as the XML-based mission script provides low-level commands to the AUV, the same mission script can be extended to define goals in an agent system. This is similar to strategic level commands. (Duane 1996) The agents can be developed using Connector-based MultiAgent System (CMAS) library. (Hiles 2004)

AUV reactions are based on its onboard suite of sensors (e.g., when a mine is encountered, loiter to verify, or surface to report). Picture the following: an AUV is in water, a human controller on ship or shore running the AUV Workbench, introduces (drag-and-drop) a virtual obstacle into the virtual environment; a daemon agent pushes this piece of information out to the real AUV’s sensors to “simulate” the detection of an obstacle; the AUV in water reacts accordingly.

Instead of having cardboard enemies, we have a more realistic agent that models the enemy. This would help blur the line between simulation and real world operations and give a “practical” use of simulations. Of note, there are still issues such as bandwidth and latency with AUV communications that needs to be solved. Bolder AUV deployment concepts can be tried out; e.g., perform dynamic re-tasking once the AUV is in the water. The agent system provides data to support or confute. At the same time, the system provides details on what is the “cost” involved (in terms of potential loss of target and its endurance) when an AUV is directed to another supposedly higher priority target.

3. Development of Collaborative Sensing Strategy Using Dissimilar AUVs

The current robot execution module is based on the NPS ARIES AUV. This software can be replaced by another AUV from an industry partner or academic institution. Once implemented, NPS will have a wide variety of AUVs to try out different scenarios with dissimilar AUVs, instead of just the NPS-specific vehicles. Picture a tactical scenario whereby a planner defines the area of operations, its conditions and constraints. From a library of AUV models (which includes the virtual 3D representation and the robot software), the system comes out with a list of recommendations. The list may comprise dissimilar AUVs. The most important point is not who’s AUV is better, but how can the mission best be accomplished.
The posting of the AUV Workbench application online as open source with executable binaries makes this vision more realizable, now that developers and partners from other research institutions or industry, can download the application and work on it.

4. Simulation of Targets/Obstacles

The topic of AUV obstacle avoidance is a well-researched area. The challenge is to develop an obstacle avoidance agent that runs alongside the Workbench. At the same time, it is necessary to develop an obstacle generation or simulation module. The obstacle-simulation module dynamically introduces obstacles such as marine life or mines into the virtual environment. At the moment, under the Event Monitoring module, obstacles are displayed as targets. These targets contain only static information and are not “live”. This will cause issues when multiple sightings of the same target (e.g., mine) are reported. These will be plotted multiple times in the Workbench. A better approach is to make “live” targets, i.e., link them to a centralized agent that is responsible for the tracking and aggregation of data pertaining to targets. There can be an agent for each type of obstacles or targets, one for mines and another for ships. A target representation language using XML can be defined. A mine target may look like the one below:

```xml
<?xml version="1.0" encoding="utf-8"?>
<Target category="mine" type="subsurface"
  classification="unknown" reportedBy="AUV1"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="C:\auv\Workbench\Targets\auvTargetLanguage.xsd">
  <Report dateTime="20040101103000">
    <Position x="100" y="100" depth="15"/>
    <Size length="1" breadth="1" height="1"/>
  </Report>
  <Report dateTime="20040101104500">
    <Position x="100" y="103" depth="13"/>
    <Size length="1" breadth="1" height="1"/>
  </Report>

Figure 119. Proposed XML-based representation of Mine Target.
5. Simulation of Environmental Conditions

The real world conditions are more dynamic and unpredictable. An environment agent is responsible to feed environmental data such as sea-state and ocean current to the Workbench. To lend more realism to the virtual environment, a web service that subscribes to real weather data can be developed. A potential sub-module is to simulate interference and unreliability in communications due to weather conditions.

6. Plug-in Framework

To facilitate further development and use of the Workbench, an important addition is to have a robust component plug-in framework. This framework would consist of a plug-in manager that allows the user to add, remove or configure plug-in modules. This approach is more flexible and robust compared to compiling everything into the Workbench, which may or may not get used. The set of rules and configurations are defined in an XML schema. A sample representation is given below:

```xml
<?xml version="1.0" encoding="utf-8"?>
<Class name="Plugin" returnType="String">
  <Method name="display" returnType="void">
    <Parameter type="int" default=""/>
    <Parameter type="String" default="Description"/>
  </Method>
  <Argument value="mine.xml"/>
  <Argument value="mine.gif"/>
</Class>
```

Figure 120. XML-based representation of Plug-in Class

One approach to develop the plug-ins framework is the use of Java Reflections whereby introspection of classes (plug-in module) can be performed at runtime. Reflection enables Java code to discover information about the fields, methods and constructors of loaded classes, and to use reflected fields, methods, and constructors to operate on their underlying counterparts on objects, within security restrictions. This is an advanced topic in Java programming. Another possible approach is to use Jabber instant messaging for the communications between the plug-in modules and the Workbench application. Again, the messages are defined in an XML schema. The Jabber instant messaging solution developed in this thesis will be useful as it handles data as well as binary files.
7. **AUV Mission Manager**

An AUV Mission Manager should be introduced to handle the definition and execution of multiple AUV mission plans. The Mission Manager is responsible for the invocation and message passing between the various AUVs in the 3D display and agent environment.

A good approach to implementing the Mission Manager is to have decentralized “Execution” and “Dynamics” processes. These processes might be written as web services or agents using the Jabber protocol for data and file message exchange.

8. **User Interface Enhancements**

   a. **Manipulate Multiple Missions in 2D Mission Planner**

At the moment, the underlying software architecture supports multiple missions, but the 2D Mission Planner graphics display does not. A mission layer manager has to be added to facilitate an intuitive way for manipulating multiple missions. At the same time, it must support the ability to tie the mission scripts to specific virtual AUVs via DIS application, site and entity ID fields. A possible representation of the mission layer manager is given in Figure 121. The “eye” icon allows the user to show or hide the mission on the display.

![Mission Layer Manager in 2D Mission Planner module.](image)

   b. **Animated Icons in 2D Mission Planner and Mission Command List**

To promote a more intuitive user interface, animated icons can be introduced to depict the status of a command; e.g., when the propeller is turned on, it is animated. This gives a user a better appreciation of the current status of the mission.
commands. Similarly, the concept can be used in the 2D Mission Planner to depict important targets with a glowing red boundary. The concept of target decay (i.e., freshness of data) can be introduced using colors too; e.g., a new target has a solid color and as time passes, it becomes grayed out.

9. Distributed Robot (Execution) and Virtual Environment (Dynamics) Processes

At the moment, “Execution” and “Dynamics” processes are running on the same machine and Java Virtual Machine (JVM). The two processes use DIS multicast packets to talk to each other. In principle, both these processes are already network-capable. If both the processes are shifted to a server, it is possible to achieve a performance gain as it will offload the JVM. One approach is to implement the robot execution and virtual environment hydrodynamics using web services. The Workbench can toggle between running them on a server or local. Another approach is to use Jabber instant messaging. The AUV Workbench will package the active mission script using the method discussed in this thesis. The packaged mission script is then posted in a pre-defined chat-room. The “Execution” and “Dynamics” processes are Jabber-enabled so that they will pick up the packaged mission script and execute it.

With the server setup, the Execution and Dynamics processes are consolidated at a central location. This aids in development and testing.

The same server that functions as a Jabber server (for agent-to-agent communications through chat protocol) can also be configured as a web server (specifically Apache Tomcat).

10. Compression and Error-Correction Algorithms

Data compression is important in the operation of AUVs. Water density inhibits transmission of radio and light waves. Although sound travels quite well, currently achievable data transmission rates are poor in comparison to land-based communications.
A likely candidate for data compression is an in-house developed compression scheme, Cross Format Schema Protocol (XFSP) [Serin 2003] or XML Schema-based Binary Compression (XSBC). XSBC is schema-based XML binary serialization and compression.

In addition to compression, data error correction and recovery schemes can be introduced as acoustic shallow-water data transmissions are known to be unreliable and an autonomous entity will often experience problems when passing a message to its intended receiver. According to thesis work performed in 1995, Forward Error Correction (FEC) can reduce the number of required retransmissions by 3 to 15 percent. FEC is a “method of data encoding that gives the receiver the ability to correct data received in error up to a preset bound.” FEC can be easily implemented, the most basic implementation requiring the use of a simple Hamming code. [Reimers 1995] As with the implementation of an XML-based mission control language, one goal of FEC is standardization of the underwater acoustic data communications community (after Reimers, 1995).

The study and introduction of encryption and decryption algorithms is important as AUVs are tasked to perform covert missions.

11. Mapping Capability in Mission Planner

The current version of the mission planner does not have any mapping capability. There are several commercial and Open Source products available to add mapping and geo-referencing capability to the Workbench. OpenMap is an Open Source Java Beans based toolkit for building applications and applets needing geographic information. Using OpenMap components, you can access data from legacy applications, in-place, in a distributed setting. At its core, OpenMap is a set of Swing components that understand geographic coordinates. The technology base underlying OpenMap was developed under government funding. From 1987 - 1992, BBN was involved in a DARPA collaborative mapping research project [http://openmap.bbn.com/](http://openmap.bbn.com/) (Accessed February 2004). Another open-source product is GeoTools. GeoTools is an open source Java toolkit for developing interactive geographical maps. The emphasis is on client side mapping applets that
require little or no server side support. The main file format for the moment is the ESRI Shapefile (.shp). [http://geotools.sourceforge.net/](http://geotools.sourceforge.net/) (Accessed February 2004). There are two commercial solutions identified. They are iLog Jviews and ESRI Java MapObjects. ILOG JVviews Maps Package provides a full range of features, including geo-referencing for easy placement of assets in proper locations, mix-and-match vector and raster data in the same map and the ability to handle multiple projections of the earth's surface. It has built in load-on-demand for efficiently handling large sets of map data [www.ilog.com](http://www.ilog.com) (Accessed February 2004). An important feature as the Workbench acquires Geographic Information Systems (GIS) capability. ESRI Java MapObjects is a powerful collection of pure Java components that allows developers to build custom, cross platform, mapping and spatially enabled applications. With a robust collection of pure Java GIS and mapping components, including a suite of pre-defined visual JavaBeans, MapObjects—Java Edition provides developers with the tools to create client or server-side applications for stand-alone deployments or delivery over the Web [www.esri.com](http://www.esri.com) (Accessed February 2004). A list of open-source and free GIS related software projects are available on [http://opensourcegis.org/](http://opensourcegis.org/) (Accessed February 2004).

C. SUMMARY

Conclusion and future work recommendations are collected in this chapter. The goal of implementing a common platform for AUV mission planning and analysis has been achieved. At the same time, this thesis has shown that Jabber, an open-standards technology for instant messaging, is a viable solution to facilitate text and file messaging for humans as well as agent communications. Exemplars have demonstrated how in-mission and post-mission event monitoring by human operators can be achieved via simple web page, standard clients, or custom instant messaging client. Finally, the AUV Workbench is a potential tool for the development of multiple-AUV deployment concepts, tactics and doctrine.

APPENDIX B. LIST OF ARIES AUV-SPECIFIC EXECUTION-LEVEL COMMANDS

A. INTRODUCTION

This appendix consists of the list of ARIES AUV-specific execution level commands along with attribute types and example values. This language remains under developed; particularly with respect to in-water exception handling.

B. XML-BASED EXECUTION LEVEL COMMANDS

1. <Depth> Element

<Depth> sets commanded vehicle depth. Sample given below:

```
<Depth value="10"/>
```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Format/Type</th>
<th>Default</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>value</td>
<td>Depth value</td>
<td>Decimal</td>
<td>0.0</td>
<td>N</td>
</tr>
</tbody>
</table>

2. <EnterTube> Element

<EnterTube> commands the vehicle to enter a specified recovery tube. Vehicle initial position needs to be directly in front of opening, but heading can be off. Sample given below:

```
<EnterTube recoveryRange="5" recoveryHeading="270"/>
```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>recoveryRange</td>
<td>Range from vehicle's current location to final recovery position.</td>
<td>Decimal</td>
<td>-</td>
<td>Y</td>
</tr>
<tr>
<td>2.</td>
<td>recoveryHeading</td>
<td>Recovery heading (must match orientation of the tube).</td>
<td>-</td>
<td></td>
<td>Y</td>
</tr>
<tr>
<td>3.</td>
<td>timeout</td>
<td>Specifies a max allowable time for the command (negative means no limit) before failure.</td>
<td>Decimal</td>
<td>-1.0</td>
<td>N</td>
</tr>
</tbody>
</table>
3. **<FollowLight> Element**

   `<FollowLight>` commands the vehicle to follow a light source to a recovery location. Sample given below:

   ```xml
   <FollowLight/>
   ```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
<th>Required</th>
</tr>

</tbody>
</table>
<pre><code>   |        | (negative means no limit) before failure.       |        |         |          |
</code></pre>

4. **<GpsFix> Element**

   `<GpsFix>` orders the vehicle to surface for a GPS fix or resume mission after a obtaining a GPS fix. Sample given below:

   ```xml
   <GpsFix status="complete" timeOut="5.0"/>
   ```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>

</tr>
</tbody>
</table>
<pre><code>   |        |                                                  | &quot;inProgress&quot;, &quot;complete&quot;, &quot;failed&quot;\}                          |         |          |
   |        |                                                  | Enumerated list of possible GPS |         |          |
   |        |                                                  | fix statuses.                   |         |          |
</code></pre>
<p>| 2.  | timeout | Specifies a max allowable time for the command  | Decimal                          | -1.0    | N        |
|        | (negative means no limit) before failure.       |                                  |         |          |</p>

5. **<Heading> Element**

   `<Heading>` sets commanded vehicle heading (disables waypoint or recovery control). Sample given below:

   ```xml
   <Heading value="270"/>
   ```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Format/Type</th>

</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>value</td>
<td>Course heading.</td>
<td>Decimal</td>
<td>0.0</td>
<td>N</td>
</tr>
</tbody>
</table>
6. **<Help> Element**

<Help> causes a list of valid commands to be printed to the console (if available). Sample given below:

```xml
<Help/>
```

7. **<Hover> Element**

<Hover> commands the vehicle maintain position at a specified (x,y) position. It can include heading and depth command. Sample given below:

```xml
<Hover x="200" y="100" z="15" heading="270" standoff="2.5"/>
```

<table>
<thead>
<tr>

<td>timeOut attribute specifies a max allowable time for the command (negative means no limit) before failure.</td>
<td>decimal</td>
<td>-1.0</td>
<td>N</td>
</tr>
</tbody>
</table>

8. **<Lateral> Element**

<Lateral> sets both lateral thrusters to cause vehicle to slide right or left (turns off all automatic control modes). Sample given below:

```xml
<Lateral speed="10"/>
```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>

</tbody>
</table>
9.  **<MissionScript> Element**

    <MissionScript> loads a new mission script from a specified file. Sample given below:

    ```xml
    <MissionScript fileName="sample.xml"/>
    ```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Format/Type</th>

<td></td>
</tr>
</tbody>
</table>

10. **<Pause> Element**

    <Pause> temporarily suspends vehicle operation (for bench test or virtual world use only), useful for getting evaluation checkpoints during testing. Sample given below:

    ```xml
    <Pause/>
    ```

11. **<Planes> Element**

    <Planes> sets bow and/or stern plane deflection angle (turns off all automatic control modes). Sample given below:

    ```xml
    <Planes which="stern" value="-25"/>
    ```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Format/Type</th>
<th>Default</th>
<th>Required</th>
</tr>
</thead>
</table>
| 1.  | which   | Set planes  | AvailablePlanes = {"bow", "stern", "both"}
      |          |             | Enumerator list of manually settable control planes. | both | N        |
| 2.  | value   | Angle of deflection. | Decimal   | 0.0     | N        |

12. **<Position> Element**

    <Position> updates of vehicle position in the world (new navigation fix has been obtained). It sets GPS zero point if not previously done. Sample given below:

    ```xml
    <Position x="12" y="55" depth="5"/>
    ```
<table>
<thead>
<tr>
<th>S/N</th>
<th>Attribute</th>
<th>Description</th>

</tr>
</tbody>
</table>

### 13.  <Propeller> Element

<Propeller> manually set one or both propeller speeds. Sample given below:

```
<Propeller which="port" rpm="10"/>
```

### 14.  <Quit> Element

<Quit> ends the vehicle mission after zeroing all control settings (does not initiate surfacing procedure). Sample given below:

```
<Quit/>
```

### 15.  <RealTime> Element

<RealTime> causes execution to run in realtime (or turns realtime execution off). Sample given below:

```
<RealTime/>
```
<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Format/Type</th>

<td>value</td>
<td>Angle of deflection.</td>
<td>Decimal</td>
<td>0.0</td>
<td>N</td>
</tr>
</tbody>
</table>
19.  **<Sonar> Element**

*<Sonar>* commands the vehicle to assume a specified fixed station relative to a sonar target. Sample given below:

```xml
<Sonar sonarHardware="ST1000" scanMode="manual" bearing="180" bearingType="relative"/>
```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>

<td>Angles measured from bow/north clockwise when viewed from above. Matches a standard compass rose.</td>
<td>BearingTypes= {&quot;relative&quot;, &quot;true&quot;, &quot;magnetic&quot;}</td>
<td>relative</td>
<td>N</td>
</tr>
</tbody>
</table>

20.  **<Standoff> Element**

*<Standoff>* resets the acceptable standoff radius in meters around hover-points and waypoints. Sample given below:

```xml
<Standoff range="15.0"/>
```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Format/Type</th>
<th>Default</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Range</td>
<td>Stand-off distance.</td>
<td>Decimal</td>
<td>2.5</td>
<td>N</td>
</tr>
</tbody>
</table>
21.  \textit{<TakeStation>} Element

\textit{<TakeStation>} commands the vehicle to assume a specified fixed station relative to a sonar target. Sample given below:

\begin{verbatim}
<TakeStation sonarScanMode="target" targetRange="5" targetBearing="90" commandRange="5" commandBearing="45" heading="270"/>
\end{verbatim}

<table>
<thead>
<tr>
<th>S/N</th>

</tr>
<tr>
<td>7.</td>
<td>timeout</td>
<td>Specifies a max allowable time for the command (negative means no limit) before failure.</td>
<td>Decimal</td>
<td>-1.0</td>
<td>N</td>
</tr>
</tbody>
</table>
22. <Thrusters> Element

<Thrusters> enables or disables the vehicle’s vertical and lateral thrusters (can be overridden by some control commands). Sample given below:

```xml
<Thrusters on="true"/>
```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Format/Type</th>
<th>Default</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>On</td>
<td>Specifies a max allowable time for the command (negative means no limit) before failure.</td>
<td>Boolean</td>

<td>N</td>
</tr>
<tr>
<td>2.</td>
<td>which</td>
<td>Location.</td>
<td>AvailableThrusters = {&quot;lateral&quot;, &quot;vertical&quot;, &quot;bowLateral&quot;, &quot;sternLateral&quot;, &quot;bowVertical&quot;, &quot;sternVertical&quot;}</td>
<td>-</td>
<td>N</td>
</tr>
</tbody>
</table>

23. <TimeStep> Element

<TimeStep> resets the elapsed time for each closed loop control cycle (default is 0.1 sec or 10 hz). Faster on-board computers and faster analog-to-digital (A/D and D/A) conversions permits shorter timestep periods. Sample given below:

```xml
<TimeStep period="0.5"/>
```

<table>
<thead>
<tr>
<th>S/N</th>
<th>Command</th>
<th>Description</th>
<th>Format/Type</th>
<th>Default</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Period</td>
<td>Loop interval.</td>
<td>Decimal</td>
<td>0.1</td>
<td>N</td>
</tr>
</tbody>
</table>

24. <Trace> Element

<Trace> turns vehicle trace feature on or off. Sample given below:

```xml

C. MISSION PLANNING

The mission package is responsible to render two-dimensional mission planner view on the top-right display pane.

Directory location: `<CDRom>\auv\Workbench\src\mission`

<table>
<thead>
<tr>
<th>S/N</th>
<th>Filename</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Mission.java</td>
<td>Data structure to store Mission information.</td>
</tr>
<tr>
<td>2.</td>
<td>MissionBoundBoxView.java</td>
<td>User interface to define the mission bounding box (area of interest) (Not used).</td>
</tr>
<tr>
<td>7.</td>
<td>MissionEnterTube.java</td>
<td>Mission EnterTube command data structure. It commands the vehicle to enter a specified recovery tube. Vehicle should be directly in front of opening, but heading can be off.</td>
</tr>
<tr>
<td>8.</td>
<td>MissionFollowLight.java</td>
<td>Mission FollowLight command data structure. It commands the vehicle to follow a light source to a recovery location.</td>
</tr>
<tr>
<td>9.</td>
<td>MissionHeading.java</td>
<td>Mission Heading command data structure. It sets commanded vehicle heading (disables waypoint or recovery control).</td>
</tr>
<tr>
<td>10.</td>
<td>MissionHelp.java</td>
<td>Mission Help command data structure. It causes a list of valid commands to be printed to the console (if available).</td>
</tr>
<tr>
<td>11.</td>
<td>MissionHover.java</td>
<td>Mission Hover command data structure. It commands the vehicle maintain position at a specified (x,y) position. It can include heading and depth command.</td>
</tr>
<tr>
<td>12.</td>
<td>MissionInputOneView.java</td>
<td>User interface to capture a single value input (boolean, integer) from user. It is invoked by MissionDialog.</td>
</tr>
<tr>
<td>13.</td>
<td>MissionLateral.java</td>
<td>Mission Lateral command data structure. It sets both lateral thrusters to cause vehicle to slide right or left (turns off all automatic control modes).</td>
</tr>

<td>Customized cell rendering in a JList (e.g., loading of icons and setting of colors).</td>
</tr>
<tr>
<td>17.</td>
<td>MissionPause.java</td>
<td>Mission Pause command data structure. It temporarily suspends vehicle operation (for bench test or virtual world use only); useful for getting evaluation checkpoints during testing.</td>
</tr>
<tr>
<td>18.</td>
<td>MissionPlanes.java</td>
<td>Mission Planes command data structure. Set bow and/or stern plane deflection angle (turns off all automatic control modes).</td>
</tr>
<tr>
<td>20.</td>
<td>MissionPointView.java</td>
<td>Mission Point user interface to manipulate MissionPoint data (includes Hover, Position, Waypoint).</td>
</tr>
<tr>
<td>21.</td>
<td>MissionPosition.java</td>
<td>Mission Position command data structure. It updates of vehicle position in the world (new navigation fix has been obtained). It sets GPS zero point if not previously done.</td>
</tr>
<tr>
<td>22.</td>
<td>MissionPropeller.java</td>
<td>Mission Propeller command data structure. It manually set one or both propeller speeds.</td>
</tr>
<tr>
<td>23.</td>
<td>MissionQuit.java</td>
<td>Mission Quit command data structure. It ends the vehicle mission after zeroing all control settings (does not initiate surfacing procedure).</td>
</tr>
<tr>
<td>24.</td>
<td>MissionRealtime.java</td>
<td>Mission RealTime Command Information. It causes execution to run in realtime (or turns realtime execution off).</td>
</tr>
<tr>
<td>25.</td>
<td>MissionResetTime.java</td>
<td>Mission ResetTime command data structure. It resets the vehicle time to a specified value.</td>
</tr>
<tr>
<td>26.</td>
<td>MissionRotate.java</td>
<td>Mission Rotate command data structure. It sets both lateral thrusters to cause vehicle to rotate (turns off all automatic control modes).</td>
</tr>
<tr>
<td>27.</td>
<td>MissionRudder.java</td>
<td>Mission Rudder command data structure. It sets rudder deflection (turns off all automatic control modes).</td>
</tr>
<tr>
<td>28.</td>
<td>MissionSonar.java</td>
<td>Mission Sonar command data structure. It commands the vehicle to assume a specified fixed station relative to a sonar target.</td>
</tr>

<td>31.</td>
<td>MissionTakeStation.java</td>
<td>Mission TakeStation command data structure. It commands the vehicle to assume a specified fixed station relative to a sonar target.</td>
</tr>
<tr>
<td>32.</td>
<td>MissionThruster.java</td>
<td>Mission Thruster command data structure. It enables or disables the vehicle’s vertical and lateral thrusters (can be overridden by some control commands).</td>
</tr>
<tr>
<td>33.</td>
<td>MissionTimeStep.java</td>
<td>Mission TimeStep command data structure. It resets the elapsed time for each closed loop control cycle (default is 0.1 sec or 10 Hz).</td>
</tr>
<tr>
<td>34.</td>
<td>MissionTrace.java</td>
<td>It turns vehicle trace feature on or off.</td>
</tr>
<tr>
<td>36.</td>
<td>MissionViewerConfig.java</td>
<td>2D mission script viewer/planner configuration file (Not implemented yet).</td>
</tr>
<tr>
<td>37.</td>
<td>MissionWait.java</td>
<td>Mission Wait command data structure. It causes the vehicle to wait a specified time before beginning execution of the next command.</td>
</tr>
<tr>
<td>38.</td>
<td>MissionWaypoint.java</td>
<td>Mission Waypoint command data structure. It commands the vehicle to transit to a specified location.</td>
</tr>
<tr>
<td>39.</td>
<td>TargetMine.java</td>
<td>Target mine data structure.</td>
</tr>
</tbody>
</table>

### D. JABBER INSTANT MESSAGING

The `im` package is used for standard Jabber instant messaging. It also implements the XTC Event Monitoring module (including the triggering of watch events and raising of alerts).

**Directory location:** `<CDRom>\auv\Workbench\src\im`

<table>
<thead>
<tr>
<th>S/N</th>
<th>Filename</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>AgentConfig.java</td>
<td>Data structure to store agent configuration that has been loaded from an XML file.</td>
</tr>
<tr>
<td>2.</td>
<td>Alert.java</td>
<td>Data structure to store alert. AlertSound, AlertURL and AlertVisual inherit from this class.</td>
</tr>
<tr>
<td>3.</td>
<td>AlertSound.java</td>
<td>Data structure for Sound Alerts, e.g., <code>&lt;Alert type=&quot;sound&quot; src=&quot;sound/beep.au&quot;/&gt;</code>.</td>
</tr>
</tbody>
</table>
5. AlertVisual.java  Data structure for Visual Alerts, e.g., `<Alert type="visual" src="image/mine.gif"/>

6. IMConfig.java  Instant messaging session object.

7. Monitor.java  Event monitoring criteria for Jabber messages.

8. UIAgent.java  Event Monitoring/Jabber Instant Messaging User Interface.

9. WatchEvent.java  Data structure to store Watch Event and its corresponding alerts/actions.

E. WEB
The web server module is implemented in the web package.

Directory location: `<CDRom\auv\Workbench\src\web`

<table>
<thead>
<tr>
<th>S/N</th>
<th>Filename</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>HandleRequest.java</td>
<td>Thread to handle incoming web server requests.</td>
</tr>
<tr>
<td>2.</td>
<td>HTTPServer.java</td>
<td>Web server to receive HTTP requests.</td>
</tr>
<tr>
<td>3.</td>
<td>PostForm.java</td>
<td>HTTP POST data structure.</td>
</tr>
<tr>
<td>4.</td>
<td>RequestHTTP.java</td>
<td>Processing of incoming web server requests.</td>

<td>Data structure to store binary file data in XHTML portion of Jabber message.</td>
</tr>
<tr>
<td>2.</td>
<td>FileFilterEx.java</td>
<td>Define a file filter (extension, description) in drop-down combo-box</td>
</tr>
<tr>
<td>3.</td>
<td>FontDialog.java</td>
<td>Selection of font type or allow typed-in text string, e.g., used in drawing application.</td>
</tr>
<tr>
<td>4.</td>
<td>IconFileView.java</td>
<td>Display an icon for a particular file types.</td>
</tr>
<tr>
<td>5.</td>
<td>ImageDisplay.java</td>
<td>Image viewer for the following formats: BMP, GIF, PNG, JPEG and SVG (using Batik).</td>
</tr>
<tr>
<td>6.</td>
<td>NumericInputHandler.java</td>
<td>To restrict the no. of characters permitted in the JTextField.</td>
</tr>
<tr>
<td>7.</td>
<td>SortedList.java</td>
<td>Sorted JList component.</td>
</tr>
<tr>
<td>8.</td>
<td>SplashScreen.java</td>
<td>Splash screen.</td>
</tr>
<tr>
<td>9.</td>
<td>SystemMedia.java</td>
<td>System Utilities to manipulate media files e.g.,</td>
</tr>
</tbody>
</table>
10. SystemUtil.java
   System Utilities to perform file copy, extract file name, directory, name only, property management and screen-capture.

11. SystemUtilX.java
   Extra System Utilities to perform base-64 encoding & decoding, ZIP, GZIP and HTTP file retrieval

</table>
H. CONFIGURATION FILE

The AUV Workbench configuration file, AUVWorkbenchConfiguration.xml, is located in directory <CDRom>\auv\Workbench\bin.
APPENDIX D. AUV WORKBENCH DEVELOPER AND USER GUIDE

A. SETUP

This document explains how to install the current version (as of March, 2004) of the AUV Workbench application. This setup procedure assumes the user is running in a Windows environment without any of the needed components installed.

3. Download and install ANT 1.6.0 or above. This is required to build the AUV Workbench application. (Available at http://ant.apache.org. Accessed on 15 February 2004).

4. Download and install Distributed Interactive Simulation module. Ensure that "dis-java-vrml.jar" (only file required) is installed in "C:\vrtp" and it is set in the "CLASSPATH".

5. Download and unzip AUV Workbench application (source and executable) into directory "C:\auv\Workbench".

6. Download and install list of applications and tools in Section C.

B. HOW TO RUN IT

By default, the AUV Workbench application shall be located in C:\auv\Workbench. To run it, go to C:\auv\Workbench\bin directory and double-click on run.bat.
C. HOW TO COMPILE IT
To compile and build the AUV Workbench application, go to C:\auv\Workbench\ directory and double-click on antbuild.bat.

D. TOOLS AND APPLICATIONS
List of tools and useful applications:

<table>
<thead>
<tr>
<th>S/N</th>
<th>Name</th>
<th>Version</th>
<th>Description</th>
<th>Available at</th>
</tr>
</thead>
</table>

E. FREQUENTLY ASKED QUESTIONS (FAQ)
1. Unable to Start AUV Application
   - Install Java JDK 1.4.2.
   - Install Java 3D.
   - Go to AUV's "\bin" directory, double-click on "run.bat".
   - List of files that are required by Java3D:
   - J3D.dll, J3DUtils.dll, j3daudio.dll located in %JAVA_HOME/jre/bin.
vecmath.jar, j3dcore.jar, j3dutils.jar, j3daudio.jar located in 
%JAVA_HOME%/jre/lib/ext.
