ABSTRACT. This study investigates the Drosophilidae species associated to fruiting bodies of fungi in forested and anthropized environments of the Atlantic Rain Forest Biome, in south and southeastern Brazil. We collected samples of imagoes flying over and emerging from fruiting bodies of species of five fungi families, in six collection sites. We obtained 18 samples, from which emerged 910 drosophilids of 31 species from the genera *Drosophila* Fallen, 1823, *Hirtodrosophila* Duda, 1923, *Leucophenga* Mik, 1886, *Mycodrosophila* Oldenberg, 1914, *Scaptomyza* Hardy, 1849, *Zaprionus* Coquillett, 1901 and *Zygothrica* Wiedemann, 1830. The *Drosophila* species collected on fungi, as well as *Zaprionus indianus* Gupta, 1970, had previously been recorded colonizing fruits, demonstrating their versatility in resource use. Most of these species belong to the *immigrans-tripunctata* radiation of *Drosophila*. Our records expands the mycophagous habit (feeding or breeding on fungi) to almost all species groups of this radiation in the Neotropical region, even those supposed to be exclusively frugivorous. Assemblages associated to fungi of forested areas were more heterogeneous in terms of species composition, while those associated to fungi of anthropized areas were more homogeneous. The drosophilids from anthropized areas were also more versatile in resource use.

KEYWORDS. *Drosophila*, mycophagous insects, feeding sites, breeding sites.

RESUMO. Drosophilidae (Diptera) associados a fungos: uso diferenciado de recursos em áreas antrópicas e de Mata Atlântica. Foi realizado um estudo das espécies de Drosophilidae associadas aos corpos de frutificação de fungos em ambientes florestais e antrópicos no Bioma Mata Atlântica, no sul e sudeste do Brasil. Foram realizadas coletas de adultos sobrevoando e emergindo de corpos de frutificação de espécies de fungos de cinco famílias, em seis pontos de coleta. Foram obtidas 18 amostras, onde foram coletados 910 indivíduos de 31 espécies, pertencentes aos gêneros *Drosophila* Fallen, 1823, *Hirtodrosophila* Duda, 1923, *Leucophenga* Mik, 1886, *Mycodrosophila* Oldenberg, 1914, *Scaptomyza* Hardy, 1849, *Zaprionus* Coquillett, 1901 e *Zygothrica* Wiedemann, 1830. As espécies de *Drosophila* coletadas, assim como *Zaprionus indianus* Gupta, 1970, já haviam sido registradas em frutos, evidenciando sua versatilidade na utilização dos recursos. A maioria destas espécies pertence à radiação *immigrans-tripunctata* de *Drosophila*. Em espécies desta radiação que habitam regiões temperadas, a micofagia é amplamente difundida; nossos registros (de sítios de alimentação e oviposição em fungos) expandem este hábito para quase todos os grupos de espécies desta radiação na região Neotropical, mesmo aquelas que se supunham ser exclusivamente frugívoras. As assembléias colonizadoras dos corpos de frutificação variaram entre as espécies de fungos e com o tipo de ambiente em que eles se desenvolviam, onde as espécies de drosophilídeos generalistas utilizam os fungos em ambientes mais degradados.

PALAVRAS-CHAVES. *Drosophila*, insetos micófagos, sítios de alimentação, sítios de oviposição.

Mycophagy has manifested itself several times in the evolution of Drosophilidae, and it is very likely that it derived from detritivorous habits (THROCKMORTON, 1975). Some genera, like *Drosophila* Fallen, 1823, *Leucophenga* Mik, 1886 and *Scaptomyza* Hardy, 1849, may have acquired this habit independently (LACY, 1984; HANSKI, 1989; COURTNEY *et al.*, 1990). Yet, apparently this characteristic is synapomorphic in drosophilids of the *Zygothrica* genus group, a tropical taxa which includes the genera *Hirtodrosophila* Duda, 1923, *Mycodrosophila* Oldenberg, 1914, and *Zygothrica* Wiedemann, 1830 as main representatives (GRIMALDI, 1990).

Almost all studies on mycophagous drosophilids have been conducted in North America, Europe and Japan (COURTNEY *et al.*, 1990; BURLA *et al.*, 1991; TODA *et al.*, 1999; YAMASHIDA & HIJII, 2007), and indicate that *Drosophila* is a genus that abounds in fungi fruiting bodies, and that it may even represent the majority of

Diptera that emerge from this substrate (TODA *et al.*, 1999). These investigations also offer evidences that most mycophagous *Drosophila* species known belong to the *pinicola*, *quinaria*, *testacea* and *tripunctata* species groups, all of which are included in the *immigrans-tripunctata* radiation (REMSEN & O'GRADY, 2002; MARKOW & O'GRADY, 2005).

Some of these temperate zone species were used as model organisms in several studies on field and experimental ecology and offered significant contributions. However, concerning the Neotropical region, the information available about this guild is scarce. Samples were obtained from the 1940's up to the 1960's (FROTA-PESSOA, 1945, 1951; CORDEIRO, 1952; BURLA, 1956; MOURÃO *et al.*, 1965), in studies whose aims were not to investigate the ecology of these species. Later, in a revision of the *Zygothrica* genus, GRIMALDI (1987) collected individuals in Peru and observed that few

species of the genus oviposit in fungi, while some use them as courtship site. VAL & KANESHIRO (1988) carried out a survey in the Atlantic Rain Forest with commercial fungi and banana baits, and *Zygothrica* was the most abundant genus after *Drosophila*, with almost 50 species identified. Recently, ROQUE *et al.* (2006) collected drosophilids flying over and emerging from fruiting bodies of *Pleurotus* sp. (Tricholomataceae, Agaricales) and another undetermined fungus at the *Cerrado* Biome, Central Brazil, where 20 species from five genera of Drosophilidae were collected, and *Drosophila* was the most abundant.

Although there have been important studies on the ecology of mycophagous drosophilids, they were conducted in temperate zones, where the diversity of Drosophilidae are lower than those found inhabiting other regions. Therefore, it becomes necessary to discover whether the processes and patterns found in temperate zones are applicable in tropical zones. In this context, the aim of the present study is to contribute to the understanding of the processes driving the colonizing patterns of mycophagous drosophilids, by analyzing and comparing the drosophilid assemblage associated to fruiting bodies of fungi in the Atlantic Rain Forest *stricto sensu* and anthropic areas, in south and southeastern Brazil.

MATERIAL AND METHODS

Drosophilids and fungi were collected in six sites in south (States of Rio Grande do Sul and Santa Catarina) and southeast regions of Brazil (State of São Paulo) (Fig. 1). Samplings were conducted at three environments of the Atlantic Rain Forest *stricto sensu* and three anthropic areas, near buildings or gardens (Tab. I).

To evaluate the probable feeding sites of mycophagous Drosophilidae species, adult flies flying over fructification bodies of fungi were captured in the field by sweeping with an entomological net or with an entomological aspirator. To assess the breeding sites of Drosophilidae species, fructification bodies of fungi were collected, brought to the laboratory and kept in glass vials with sterilized sand. Vials were maintained in controlled temperature at $24 \pm 1^\circ\text{C}$. Water was added whenever necessary to prevent dehydration. Emerged adults were aspired daily.

Drosophilid identification was based on external morphology and on male genitalia (prepared according to WHEELER & KAMBYSELLIS, 1966, modified by KANESHIRO, 1969). Voucher specimens were deposited at the Museu de Ciências Naturais, Fundação Zoobotânica do Rio Grande do Sul (MCN/FZB), and Museu de Zoologia, Universidade de São Paulo (MZSP). Fungi identification was conducted using a dichotomic key (GUERRERO & HOMRICH, 1999).

To test the association between drosophilid species and feeding sites, we conducted a Detrended Correspondence Analysis (DCA) (HILL & GAUCH, 1980), where the drosophilid species that flew over the fruiting bodies were the descriptors and fungi taxa were the

objects. Another DCA was used to test an association between drosophilid species and breeding sites (fungi taxa), where the former were the descriptors and the latter the objects. DCA is an ordination analysis and, similarly to the Correspondence Analysis, it has been proposed as a way to analyze two-way contingency tables. However, DCA removes the arch effect found in most ordination analysis. DCA was conducted on the software R 2.5.0 (R DEVELOPMENT CORE TEAM, 2007), with the VEGAN package 1.8-8 (OKSANEN *et al.*, 2007), and it was based on 26 segments, as recommended by HILL & GAUCH (1980).

RESULTS

A total of 910 individuals belonging to 31 Drosophilidae species were collected (Tabs. I, II). Among the drosophilid genera collected, *Drosophila* was the richest (17 species) and the most abundant in all environments sampled, even when compared to other exclusively mycophagous species, like *Hirtodrosophila* (five species), *Leucophenga* (two species) and *Mycodrosophila* (two species).

Figure 1. South America map indicating the sampled sites in Brazil of the Drosophilidae species associated to fruiting bodies of fungi in forested and anthropized environments (A, Campus of Universidade Federal do Rio Grande do Sul, Porto Alegre, RS; B, Campus of Universidade de São Paulo, Ribeirão Preto, SP; C, Campus of Universidade Federal de Santa Catarina, Florianópolis, SC; D, Morro da Lagoa da Conceição, Florianópolis, SC; E, Biguaçu, SC; F, Pirafé, Joinville, SC).

Considering all sites sampled, 90 individuals were collected flying over fructification bodies, totaling 21 fly species, of which 14 belonged to the genus *Drosophila* (Table III). At least four fungi species (probably used as feeding sites) were identified: *Coprinus comatus* (Agaricaceae, Agaricales), *Phallus* sp. (Phallaceae, Agaricales) and one species of Agaricales

sampled in anthropic areas; one member of the Polyporaceae family and a group of several undetermined fungi species sampled in forest areas. In the DCA conducted for the specimens collected flying over fruiting bodies, the components 1 and 2 accounted for 40.9 % of data variation. Our analysis distinguished between generalist and specialist fly species (Fig. 2).

Generalist Drosophilidae species generated dots closer to the point of origin of axes, and occurred mainly in association with *C. comatus* samples, that was found in the anthropized environments and which had also more homogeneous assemblages. The dots of the more specialist drosophilids are farther away from the point of origin, just as the dots representing more heterogeneous assemblages associated to feeding sites.

Specimens of four fungi families (Agaricaceae, Auriculariaceae, Marasmiaceae and Polyporaceae) were collected and brought to the laboratory, of which 820 drosophilids emerged (Tab. IV). *Drosophila* was once again the richest and most abundant genus, with ten species and 273 individuals. In the DCA for species that emerged from the fructification bodies (breeding sites) (Fig. 3), the components 1 and 2 accounted for 14.8% of data variation. Exactly as observed in feeding

sites, the composition of breeding Drosophilidae from fungi of anthropized areas (*C. comatus*, *Macrolepiota* sp., *Marasmius* sp. and Agaricales *latu sensu*) was more homogeneous. Similar situation was observed regarding the presence of more generalist species. This is highlighted by the clustering of dots next to the point of origin of the chart's axes. The fauna emerged from Polyporaceae, that was found mainly in the forest areas, was typical and distinct from that of other fungi, including specialized Drosophilidae genera, as *Hirtodrosophila*, *Mycodrosophila* and *Zygothrica*. The Atlantic Rain Forest samples were likewise more heterogeneous regarding composition of colonizing species (evidenced by respective dots distant from the point of origin), and the species that colonized fungi from the woods were observed exclusively in these samples.

DISCUSSION

As a whole, our results indicate that mycophagy is far more common than previously thought, since the present records expands the mycophagous habit (feeding or breeding on fungi) to almost all species groups of *immigrans-tripunctata* in the Neotropical region, even those supposed to be exclusively frugivorous. The species of *calloptera*, *cardini*, *guarani* and *tripunctata* species groups of *Drosophila*, all belonging to the *immigrans-tripunctata* radiation (REMSEN & O'GRADY, 2002; MARKOW & O'GRADY, 2005), were frequent in our samples (except for Polyporaceae). The same had been previously observed in a study conducted in central Brazil by ROQUE *et al.* (2006). Most of the species belonging to the *testacea* and *quinaria* species groups of *Drosophila*, which also belong to the *immigrans-tripunctata* radiation, are obligatory mycophagous flies. The characteristics related to the use of fungi by species of the *immigrans-tripunctata* radiation may thus be synapomorphic, since all its species groups, with the exception of *pallidipennis*, were recorded colonizing fungi. However, the homoplasy hypothesis cannot be rejected.

The occurrence of *Hirtodrosophila*, *Leucophenga*, *Mycodrosophila*, *Scaptomyza* and *Zygothrica* in fungi lends more consistency to the existing literature records (GRIMALDI, 1987; VAL & KANESHIRO, 1988; COURTNEY *et al.*, 1990). Nevertheless, the presence of *Zaprionus* Coquillett, 1901 in our samples attracted our interest, as the only species observed in the Neotropics, *Z. indianus*, is considered to be frugivorous. Adult specimens of *Z. indianus* were collected over fruiting bodies of *Phallus* sp. (Phallaceae, Phallales) in anthropized areas of Ribeirão Preto (São Paulo, Brazil), and two individuals emerged from fungi collected by ROQUE *et al.* (2006). Taken together, these data demonstrate the versatility of this species, which recently invaded the American continent and is considered a pest for fruit production (VILELA *et al.*, 2000).

Drosophilid assemblages associated to Polyporaceae were distinct from that associated to fungi of other families, considering both breeding and feeding sites. The dominance of *Hirtodrosophila*, *Mycodrosophila* and *Zygothrica* species may be linked to higher frequencies of this fungus family in Atlantic Rain Forest areas, since it is possible that the richness of these drosophilid genera is higher in forests, as suggested by SPIETH (1987) and COURTNEY *et al.* (1990). In these forested areas, the assemblages were more heterogeneous regarding their composition. In contrast, the fauna emerging from the Agaricaceae, Auriculariaceae, Marasmiaceae and Phallaceae families, more abundant at anthropized areas, was far more homogeneous, with dominance of *Drosophila* species.

In the present study, the *cardini* species group of *Drosophila* (*D. cardini* Sturtevant, 1916, *D. cardinoides* Dobzhansky & Pavan, 1943 and *D. neocardini* Streisinger, 1946) was restricted to the anthropized environments, since these species were observed only in fungi collected in these areas. The low abundance of such species in forested areas, in contrast with the high abundance observed in anthropic ones, was also recorded by GOTTSCHALK *et al.* (2007), though using banana baits.

Similarly, the *calloptera* group, in spite of the low abundance observed, was restricted to forest areas, what have also been observed in banana-baited collections (DE TONI *et al.*, 2007). On the other hand, species of the *tripunctata* and *guarani* species groups were observed in fungi collected in both forested and anthropized environments.

In the present study, 31 Drosophilidae species were collected associated to fungi fruiting bodies in the Atlantic Rain Forest and urbanized areas. Of these species, those belonging to the *Drosophila* and *Zaprionus* genera were also collected associated to fruits in other studies (CARSON, 1971; SILVA *et al.*, 2005; GARCIA *et al.*, 2008), demonstrating their versatility in resource use. The use of fungi as a trophic resource has probably played a more significant role, in comparison to previous notions, in the evolutive success of Neotropical species belonging to the *immigrans-tripunctata* radiation of *Drosophila*. Assemblages associated to fungi of forested areas were more heterogeneous in terms of species composition, while those associated to fungi of anthropized areas were more homogeneous at species level. The species of the *cardini* groups of *Drosophila* was restricted to anthropized areas, while the *calloptera* species group was restricted to forested areas. The drosophilids from anthropized areas were also more versatile in resource use, since they were collected in several samples of feeding and breeding sites.

Acknowledgments. The authors are grateful to Monica Laner Blauth, Diogo Andrade Costa, Rosana Tidon, Victor Hugo Valiati, Helena Piccoli Romanowski and two anonymous referees for the suggestions kindly offered as of manuscript preparation, to Juliana Cordeiro and Hermes José Schmitz for the assistance in the collections, to Felix Nonnenmacher for the help with English version of the manuscript, and to Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES), Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) and the Fundação de Apoio da Universidade Federal do Rio Grande do Sul (FAURGS) for the financial support granted.
