ABSTRACT

Purpose: To compare the perioperative complication rate obtained with the transperitoneal laparoscopic radical prostatectomy (TLRP) and with the extraperitoneal LRP (ELRP) during the learning curve (LC).

Materials and Methods: Data of the initial 40 TLRP (Group 1) were retrospectively compared with the initial 40 ELRP (Group 2). Each Group of patients was operated by two different surgeons.

Results: The overall surgical time (175 min x 267.6 min; $p < 0.001$) and estimated blood loss (177.5 mL x 292.4 mL; $p < 0.001$) were statistically better in the Group 1. Two intraoperative complications were observed in Group 1 (5%) represented by one case of bleeding and one case of rectal injury, whereas four complications (10%) were observed in Group 2, represented by two cases of bleeding, one bladder and one rectal injuries ($p = 0.675$). Open conversion occurred once in each Group (2.5%). Overall postoperative complications were similar (52.5% x 35%; $p = 0.365$). Major early postoperative complications occurred in three and in one case in Group 1 and 2, respectively. Group 1 had two peritonitis (fecal and urinary), leading to one death in this group.

Conclusions: No statistical differences in overall complication rates were observed. The transperitoneal approach presented more serious complications during the early postoperative time and this fact is attributed to the potential chance of intraperitoneal peritonitis not observed with the extraperitoneal route.

Key words: prostate; prostatic neoplasms; prostatectomy; laparoscopy

Int Braz J Urol. 2010; 36: 450-7

INTRODUCTION

Since 1998, laparoscopic radical prostatectomy (LRP) has gained worldwide popularity, based on the Montsouris initial publication with the transperitoneal LRP (TLRP) (1) followed by the Brussels initial publication with the extraperitoneal approach (ELRP) (2).

It has been ten years and so far a debate related to the approach for performing LRP, mainly during the learning curve (LC), still remains. Some authors prefer the transperitoneal approach based on the larger working space and better luminosity and others prefer the extraperitoneal counterpart, based on the lack of contact with the intraperitoneal organs (3-6).

Analyzing the comparative studies for LRP during the LC, it can be noted that the vast majority of groups started their programs using the transperitoneal approach, switching later on to the extraperitoneal route (7-9). This observation generates a bias on results, once the findings of worse results with the transperitoneal approach when compared with the extraperitoneal approach is overlooked. The results observed with the TLRP in these studies reflect the suboptimal results found during the initial phase of a LRP program and the results achieved with the extraperitoneal approach are the reflex of an “already” well-trained surgical team.

The aim of this study was to compare the initial perioperative complications obtained with both approaches used to perform LRP and identify, if possible, a more suitable approach to use during the initial stages of a LRP program.

MATERIALS AND METHODS

This retrospective study was approved by each institutional research and ethical committee. The data of the first 40 TLRP performed between March, 2004 and November, 2007 (Group 1) performed at Getúlio Vargas Hospital of Recife were recorded and compared with the first 40 ELRP performed between August, 2003 and June, 2006 (Group 2) at Clinics Hospital of State University of São Paulo.

Each group was operated by only one experienced laparoscopic urologic surgeon in two uro-laparoscopic referral centers in this country. By the time of this study, each surgeon had already performed more than 250 laparoscopic surgeries, including partial nephrectomies, radical nephrectomies, donor nephrectomies, adrenalectomies, pyeloplasties and others. Inclusion criteria were age ≤ 75 years old, clinically localized prostate tumors (cT1 and cT2N0M0), total PSA ≤ 10 ng/dL and Gleason score ≤ 7 .

Surgical Technique

All TLRP were performed by the Montsouris technique (10) while the ELRP were done by the Brussels technique (2) with some modifications.

Briefly, in the Montsouris technique, the vas deferens and seminal vesicles were firstly dissected through the retrovesical space. After entering the Retzius space and opening the endopelvic fascia, the dorsal vein complex (DVC) was tied. The bladder neck was incised, reaching the pre-dissected vas deferens. Bilaterally, the prostatic pedicles were controlled and an interfascial neurovascular bundle dissection was performed whenever possible (11). Afterwards, the DVC and urethra were cut, leaving the prostate apart for later removal. A running urethrovesical (UV) anastomosis was made in all cases of Group 1 as described by van Velthoven et al. (12).

In the Brussels technique, the Retzius space was digitally created, avoiding transperitoneal entering. The other stages were about the same as transperitoneal approach, differing only in the straight access to vas deferens and seminal vesicles after bladder neck incision. An interrupted figure of “X” UV anastomosis was performed in all patients in Group 2.

Pathological Evaluation

All fine-needle biopsies and specimens were evaluated by the uro-pathology service of each institution. Positive surgical margin (PSM) was defined as the presence of tumor at the inked margin. Tumors were graded according to the Gleason score and pathological staging was based on TNM 1997 classification.

Statistical Analysis

Analysis of variance was used to compare continuous outcome variables between both groups. The Student’s-t-test was used for homogeneous variances in each group and the Chi-square and Fisher’s exact test were used to compare categorical outcome variables. Statistical significance was defined as P value < 0.05 .

RESULTS

Preoperative data are shown in Table-1. There was a statistical difference between groups 1 and 2,

Does the Surgical Approach Affect the Complication Rate in LRP?

Table 1 – Preoperative results.

	Group 1 (n = 40)	Group 2 (n = 40)	p Value
Age (years)	59.8 ± 6.8 (46-73)	63.6 ± 7.9 (51-75)	p = 0.011
PSA (ng/dL)	5.4 ± 2.02 (2.0-10.0)	5.9 ± 1.96 (2.0-9.9)	p = 0.255
Prostatic weight (g)	36.2 ± 14.3 (20-80)	35.4 ± 20.5 (15-140)	p = 0.846
Clinical stage - n (%)			p = 0.013
T1c	32 (80%)	20 (50%)	
T2a	7 (17.5%)	15 (37.5%)	
T2b	1 (2.5%)	5 (12.5%)	
Gleason score - n (%)			p = 0.001
4 (2+2)	-	1 (2.5%)	
5 (3+2)	-	2 (5%)	
6 (3+3)	20 (50%)	32 (80%)	
7 (3+4)	14 (35%)	2 (5%)	
7 (4+3)	6 (15%)	3 (7.5%)	

PSA = prostate-specific antigen.

related to the patient's age, clinical stage and Gleason score. Clinical stage T1c was more common in Group 1 (80%) while cT2 was prevalent in Group 2 (50%). On the other hand, the Gleason score 7 was more prevalent in Group 1 (50% x 12.5%).

The intraoperative data are described in Table-2. Overall surgical time (175 min x 267.6 min; p < 0.001) and estimated blood loss (177.5 mL x 292.4

mL; p < 0.001) were statistically significant better in the Group 1. Two complications (5%) were observed in Group 1, represented by a bleeding from the DVC and rectal injury. The first one was controlled after conversion to the open approach and the last one was treated with intracorporeal suture. Four complications (10%) occurred in Group 2, represented by two cases of bleeding (5%), one bladder (2.5%) and one

Table 2 – Comparison of intraoperative data.

	Group 1 (n = 40)	Group 2 (n = 40)	p Value
Overall operative time (min)	175.0 ± 48.4 (110-360)	267.6 ± 70.57 (160-540)	p < 0.001
Blood loss (mL)	177.5 ± 148.5 (50-1000)	292.4 ± 173.7 (10-900)	p < 0.001
Open conversion - n (%)	1 (2.5%)	2 (5%)	p = 1.000
Complications - n (%)			
Overall	2 (5%)	4 (10%)	p = 0.675

Time to discharge - (days)*	3.0 (3-35)	3.0 (2-17)	p = 0.042
Early urinary continence - n (%)	27 (69.2%)	34 (85%)	p = 0.033
Sexual intercourse - n (%)	18 (45%)	17 (42.5%)	p = 0.368
Follow-up (months)	9.3 ± 7.7 (1-36)	32.9 ± 12.6 (8-50)	p < 0.001

* Median

rectal injury (2.5%). Both bleedings came from the DVC. The first one was controlled after conversion to the open approach and the last one was treated with intracorporeal suture. The bladder injury was recognized and treated by intracorporeal suture. On the other hand, the rectal injury was unrecognized in the intraoperative time and evolved with bloody anal discharge on postoperative day one, which led to an open colostomy.

Postoperative data are described in Table-3. Median time to discharge, early urinary continence and follow-up time were statistically better for Group 2. No statistical difference was observed on early postoperative sexual function, evaluated by the vaginal penetration rate whether or not using sildenafil 100 mg.

The Table-4 shows no statistical difference in overall postoperative complications (52.5% x 35%; p = 0.365). Nonetheless, sub-stratifying the complications, a statistical difference was observed by comparing the minor complications during the early and late postoperative time for each group.

The main complications observed in Group 1 were one case each of urinary sepsis, fecal and urinary peritonitis. The sepsis occurred on postoperative day (POD) 8 by *Klebsiella pneumoniae* despite preoperative negative urine culture and trans-operative use of parental ceftriaxone. The patient was readmitted and had an uneventful recovery after appropriate parenteral antibiotic therapy. The fecal peritonitis occurred on POD 4 due to fecal leakage by the rectal suture line performed intraoperatively. The patient evolved with peritonitis, sepsis and died on POD 35 even after colostomy and parenteral antibiotic therapy. The urinary peritonitis occurred due to urinary leakage from

the posterior aspect of the UV anastomosis, leading to a 1500 cc urine peritoneal collection. After open laparotomy and peritoneal drainage, the patient had an uneventful recovery.

In the Group 2, seven urinary leakages originating from the UV anastomosis occurred and were treated by prolonged bladder catheterization. Of those, six evolved with urinary strictures (bladder neck- 03; bulbar urethra- 02; and meatal urethra- 01), and had an uneventful recovery after appropriate treatment. A further urinary leakage due to the UV anastomosis evolved with a large retroperitoneal infiltration and was treated with open drainage, positioning of a tubular drain and prolonged bladder catheterization.

Lastly, the Table-5 shows the final oncological data. Comparing the results between groups 1 and 2, statistical difference was observed in the biochemical recurrence rate (5% x 20%; p = 0.043), overall incidence of PSM (10.3% x 32.5%; p = 0.016) and pathological stages (pT2: 94.8% x 70% and pT3: 5.2% x 30%; p = 0.005). Nonetheless, no difference was observed when the incidence of PSM was correlated with the pathological stages. The majority of PSM in Group 1 occurred in pT2c (75%), while this observation was more prevalent in pT3a in Group 2 (61.5%). For pT3b, 100% of PSM occurred in both groups.

COMMENTS

According van Velthoven et al. (4) and Gill et al. (13), about 92% of uro-laparoscopic centers that currently use the extraperitoneal approach, started their laparoscopic programs using the transperitoneal

Does the Surgical Approach Affect the Complication Rate in LRP?

Table 4 – Comparison of postoperative complications and reoperations.

	Group 1 (n = 40)	Group 2 (n = 40)	p Value

route. In general, this observation can cause a bias on results when these accesses are compared in the same series. Such discrepancy in results can even be greater during the initial phase of a LRP program.

Perhaps the best way to overcome the LC in LRP is the incorporation of robotics in clinical practice (14). However, even in robotic LRP, a LC does exist and so far, controversies remain about the choice of the approach to use in these cases. Moreover, the high costs associated with this technique, make it a distant reality for developing countries. Therefore, continuous improvements in LRP technique are mandatory and identification of factors that can improve and shorten the LC is imperative to achieve better results.

The main goal of this retrospective study was to compare the perioperative complication rates of two distinct groups of patients operated each by

the transperitoneal and extraperitoneal approaches during the initial phases of a LRP program. For this, each group was operated by only one urologist, having each a wide experience in retropubic radical prostatectomies and in more than 250 uro-laparoscopic surgeries. This study model, despite some points of criticism, was adopted to analyze the influence of the LC over the incidence of complications and to identify factors that could improve the results in this phase. Only Machado et al. (15) performed a similar study and observed better results with the extraperitoneal approach when compared with the transperitoneal route.

Observing the intraoperative data, the patients in Group 1 reached better surgical time and bled less than the ones in the Group 2 and these findings can be associated with the better working space and luminosity achieved with the transperitoneal access.

Does the Surgical Approach Affect the Complication Rate in LRP?

Table 5 – Postoperative pathological data.

	Group 1 (n = 39)	Group 2 (n = 40)	p Value

T3	2 (5.2%)	12 (30%)	

BPH = benign prostatic hyperplasia.

Nonetheless, two major complications were observed in Group 1, causing a urinary and fecal peritonitis, leading to the death of one patient. These results are the real reflex of the LC effect over each LRP program without any previous experience with LRP.

Urinary leakage can occur up to 28% in LRP during the LC (16-19). Of note, all seven early minor complications observed in the Group 2 were represented by urinary leakages, while only one was observed in the Group 1, which was considered a major complication. The majority of these cases evolved to urinary strictures and needed surgical treatment. In general, urinary leakages occur due to non-well aligned suture lines, surgery in prostates > 60 grams, use of interrupted sutures and when the extraperitoneal access is chosen (18,19). In general, tension over the UV anastomosis is considered higher when the extraperitoneal access is used instead of the transperitoneal route, because the bladder remains stacked on the abdominal wall by the urachus (20). In fact, based in these observations, the authors recommend the use of the UV running suture since the initial phases of the LC. Likewise, to rule out urinary leakage, filling the bladder in with 200 cc of saline after finishing the UV anastomosis is recommended.

Each group had one major complication on early postoperative time related to urinary leakage, as well as one rectal injury. In Group 1, both complications evolved to peritonitis needing reoperation, culminating in one death. On the other hand, these findings in the Group 2 evolved with less severity and went well after reoperation.

The incidence of rectal injury occurs in 1.8%-6% (8,21) and is more common during the LC (8,21). According Touijer et al. (22) and Martinez-Piñero et al. (19), the majority of injuries occur during the apical dissection. Although the rectal injury had been recognized and sutured during the intraoperative time in one patient in Group 1, the injury presented a fecal leakage on POD 4, leading to peritonitis and death. This fact was attributed to the use of the harmonic shears to dissect the posterior aspect of the prostate, near the apex. Probably, an invisible thermal injury occurred in the rectal wall during the surgery and a later wall necrosis developed, leading to the fecal leakage (19,22).

Important to notice that rectal injury can occur whatever the approach, but this complication tends to have a worse outcome when the transperitoneal route is adopted. The authors strongly recommend the

use of cold shears instead of the use of any kind of thermal shears to dissect this area to avoid this major complication, no matter which laparoscopic approach chosen.

Bladder injury is considered a rare event and is more common during the LC, reaching 8% (17,23). It can occur with both approaches and usually the injury is recognized and sutured during the surgery. In general, all injuries have an uneventful recovery after appropriate treatment.

Perineal pain is a rare event and was observed in four patients in Group 1 (10%). This was attributed to hyper abduction of legs in order to place the laparoscopic rack in between. No further cases of this type of complication were observed after discontinuation of this practice.

Epigastric artery injury occurs in about 2% - 6.2% of cases and generally is associated with trocar insertion during transperitoneal surgeries (17,23). This injury rarely occurs during ELRP, because the vessels are easily seen after the extraperitoneal space has been created. The authors suggest puncturing before the site of trocar placement with a fine needle in order to verify the route, avoiding this injury. Also is recommended to have a Carter-Thomason device readily to use if necessary.

Finally, urinary tract infection occurs in 1.4% - 2.8% in all cases of LRP, despite of antibiotic prophylaxis (2,24). Generally, these infections are caused by prolonged indwelling catheter use and/or inappropriate antibiotic prescription. Currently, the authors suggest the use of quinolones for 14 days after the hospital discharge and the urethral catheter removal as soon as possible, around the postoperative day 7.

The LRP is considered the most challenging laparoscopic surgery in urology. The greatest drawback of this surgery is its steep LC and consequently the possibility of major complications to occur and weak functional results during this time. Moreover, the initiation of a LRP program demands great caution in order to not overcome the main objective of this surgery: the cure. Therefore, continuous improvements and training are mandatory to achieve better outcomes. Based in our results, there was no difference in the incidence of perioperative complications whatever the approach used to operate both groups

during the LC. The incidence and severity of major complications were higher when the transperitoneal approach was adopted.

CONCLUSIONS

The overall complication rate was similar in both approaches. Minor complications occurred in both groups and tended to complete resolution after appropriate treatment. The higher incidence of urinary leakage in Group 2 was directed associated with the interrupted UV anastomosis and indirectly linked with the extraperitoneal route. The transperitoneal approach presented more serious complications during the early postoperative time and this fact is attributed to the potential chance of intraperitoneal peritonitis not observed with the extraperitoneal approach.
