Introduction: Patients with repaired tetralogy of Fallot (TOF) have been shown to be predisposed to exercise intolerance, arrhythmia, and premature death. Pulmonary valve replacement (PVR) reduces the amount of pulmonary regurgitation and leads to a reduced size of the right ventricular cavity. The risk-to-benefit calculus for this procedure, however, has not been well established.

Aim: To analyze the effect of PVR on several instrumental parameters and major clinical adverse events, comparing these pts with a matched operated TOF population without PVR.

Methods: From September 2003 to March 2010, 197 operated Fallot/Falot like patients were evaluated by cardiac MR exam, echocardiography, cardiopulmonary exercise testing and Amino-Terminal pro-Brain Natriuretic Peptide (NT-proBNP) blood assay. 84 of these pts were > 12 years, and had a transannular patch as primary repair, and formed our study population; 26 of them (23 ± 8 y. o.) had subsequent PVR and formed the group 1; the remaining 58 pts (age 22,5 ± 9 years) were still on transannular patch and formed the group 2. The effect of PVR on several instrumental parameters and clinical adverse outcomes was evaluated.

Results: 1 sustained ventricular tachycardia, 12 major atrial arrhythmias, 5 worsening in NYHA functional class or significant symptoms were recorded in 17 pts (9 group 1 patients (35%) and 8 in Group 2 pts (14%) corresponding to 21 % of the entire population study.

At univariate logistic regression analysis PVR was associated to reduced RV volume (O.R. 0,98 95% CI: 0,968 to 0,998, p= 0.03), reduced pulmonary regurgitation (O.R. 0,89 95% CI: 0,854 to 0,936, p< 0.01), higher RV pressure (O.R. 1,04 95% CI: 1,006 to 1,074, p= 0.02), longer Qrs duration (O.R. 1,12 95% CI: 1,04 to 1,070, p= 0.003). Conversely RV EF (O.R. 0,943 95% CI: 0,978 to 1,012, p= 0.1), NT ProBNP (O.R. 1,003 95% CI: 0,998 to 1,008, p= 0.2), Vo₂/kg/min (O.R. 0,961 95% CI: 0,879 to 0,961, p= 0.4), and tricuspid regurgitation (O.R. 2,8 95% CI: 0,908 to 8,499, p= 0.07) resulted not influenced by PVR. Moreover PVR resulted not associated to reduced major adverse events (O.R. 2,5 95% CI: 0,951 to 6,951, p= 0.06).

Conclusion: From our data, we confirm that PVR is associated to reduced RV volume and pulmonary regurgitation; but it is also associated to higher RV pressure and longer Qrs. Conversely RV EF, NT ProBNP, Vo₂/kg/min and tricuspid regurgitation resulted not influenced by PVR. Moreover PVR didn't lead to a reduction of major adverse events. Operated Fallot is a complex population with different combinations of several residual lesions as pulmonary insufficiency, pulmonary pathway stenosis, infundibular dyskinesia, tricuspid insufficiency, depending on the native anatomy and surgical procedure. These results serve as a cautionary tale; they may help to guide expectations after PVR for the patient and physician alike. At a minimum, they support continued thoughtful and systematic investigations into the specific indications for and timing of pulmonary valve replacement.
