Epstein-Barr virus (EBV) is the first human virus shown to be etiologically associated with cancer. Although EBV establishes a lifelong latent infection in >90% of the world’s population without serious sequelae, a small fraction of latently infected individuals will develop malignancies of lymphocytic and epithelial origin, such as Burkitt’s lymphoma, Hodgkin’s lymphoma, extranodal natural killer/T cell lymphoma, nasopharyngeal carcinoma (NPC), and gastric cancer (1, 2). Among nearly 100 viral genes expressed during productive replication, only 11 are expressed in latently infected cells. In addition, EBV was recently found to encode >20 microRNAs (miRNAs) (3–5).

miRNAs are gene regulatory RNAs of ~22 nt in length, and they negatively regulate gene expression either by inducing mRNA degradation or, more commonly in mammalian cells, by repressing translation (6). Cellular miRNAs are critically involved in various biological processes such as development, apoptosis, and proliferation (6). EBV was the first human virus found to encode miRNAs (3). The EBV miRNAs are organized in two clusters within the EBV genome: one in the intronic regions of the BART gene (miR-BART1 to miR-BART-20) and the other in the untranscribed regions (UTRs) of the BHRF1 gene (miR-BHRF1-1 to miR-BHRF1-3) (3–5).

Conservation of nine EBV miRNAs with counterparts in the rhesus lymphocryptovirus points to the biological importance of these viral miRNAs (4). Interestingly, miR-BARTs were found to be expressed abundantly in latently infected epithelial cells but at a significantly lower level in B cells (4), implicating a role in epithelial carcinogenesis. In further support of this, miR-BART5 rendered NPC and EBV-GC cells less sensitive to proapoptotic agents, apoptosis can be triggered by depleting miR-BART5 or inducing the expression of PUMA. Collectively, our findings suggest that EBV encodes an miRNA to facilitate the establishment of latent infection by promoting host cell survival.

Epstein-Barr virus (EBV) is a herpesvirus associated with nasopharyngeal carcinoma (NPC), gastric carcinoma (GC), and other malignancies. EBV is the first human virus found to express microRNAs (miRNAs), the functions of which remain largely unknown. We report on the regulation of a cellular protein named p53 up-regulated modulator of apoptosis (PUMA) by an EBV miRNA known as miR-BART5, which is abundantly expressed in NPC and EBV-GC cells. Modulation of PUMA expression by miR-BART5 and anti–miR-BART5 oligonucleotide was demonstrated in EBV-positive cells. In addition, PUMA was found to be significantly underexpressed in ~60% of human NPC tissues. Although expression of miR-BART5 rendered NPC and EBV-GC cells less sensitive to proapoptotic agents, apoptosis can be triggered by depleting miR-BART5 or inducing the expression of PUMA. Collectively, our findings suggest that EBV encodes an miRNA to facilitate the establishment of latent infection by promoting host cell survival.
BALF5 viral DNA polymerase to inhibit lytic replication (3, 8). Another recent study implicated the involvement of miR-BHRF1–2 in the cleavage of BHRF1 RNA in the cytoplasm (9). In contrast, an inverse correlation between expression levels of miR-BHRF1–3 and CXCL-11, which is an interferon-inducible T cell–attracting chemokine, implicated an immunomodulatory function of the viral miRNA in lymphomas (10). In addition, miR-BARTs were also found to regulate the expression of LMP1 viral oncoprotein (11). Although EBV miRNAs are important regulators of viral gene expression, they may also target cellular transcripts to facilitate viral persistence and oncogenesis. Indeed, potential cellular targets of EBV miRNAs predicted by in silico analysis include growth regulators, modulators of apoptosis, B cell–specific chemokines and cytokines, transcriptional regulators, and signal transducers (3). However, experimental evidence for the control of cellular gene expression by EBV miRNAs remains to be established.

In this study, we sought to shed light on the roles of miR-BARTs in establishing latent infection and driving carcinogenesis in epithelial cells through identification and characterization of their cellular targets. By bioinformatic analysis and functional screening, p53 up-regulated modulator of apoptosis (PUMA), also known as BBC3 (Bcl2 binding component 3), was found to be targeted by miR–BART5. PUMA is a proapoptotic protein belonging to the “BH3-only” group of the Bcl-2 family (12–14). Although it is an immediate downstream target of p53, PUMA can also induce p53-independent apoptosis in response to a wide variety of stimuli (12, 15–17). In this paper, we provide the first evidence for the suppression of PUMA expression by miR–BART5. Overexpression and loss-of-function experiments were performed to characterize the function of miR–BART5. The expression of PUMA in human NPC tissues was also examined. In addition, the functional implications of miR–BART5–mediated silencing of PUMA in the survival of EBV+ NPC and GC cells were investigated. Our work reveals a new molecular mechanism through which EBV confers resistance to apoptosis in NPC cells by counteracting the proapoptotic function of p53/PUMA with a viral miRNA.

RESULTS
Identification of PUMA as a cellular target of miR–BART5
We predicted cellular targets of all miR–BARTs using miRanda (18, 19) and RNAhybrid (20) programs, which have previously been shown to be successful in target prediction (21). The top candidates for each miR–BART (for a list of top candidates for miR–BART5 see Table S1, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1) were validated with reporter assays. Synthetic target sites were inserted into 3′ UTR of luciferase gene, and the influence of miR–BART on luciferase expression was assessed. miR–BART5 was chosen for further study because the most pronounced gene-silencing effect on a cellular target named PUMA was observed with this miRNA in the reporter assay. Actually, out of nine potential cellular targets shortlisted, PUMA was the only one that was shown to be suppressed by miR–BART5 in the reporter assay (Table S1).

The predicted miR–BART5 target site in the 3′ UTR of PUMA exhibited good complementarity to miR–BART5 and was highly conserved among human, chimp, rhesus monkey, and mouse (Fig. 1 A). Although a 7-nt stretch that perfectly matches the 5′ seed region of miR–BART5 was found in the predicted site, there were multiple mismatches in the central region (Fig. 1 A, top).

Although there are four isoforms of PUMA (α, β, γ, and δ), all isoforms conserve the same 3′ UTR and only two isoforms (PUMA-α and PUMA-β) have proapoptotic activity (13). To validate the interaction of miR–BART5 with the 3′
UTR of PUMA, luciferase reporter assays were performed. Four copies of a PUMA 3′ UTR fragment were cotransfected into HeLa cells with the miR-BART5 expression vector, in which the expression of miR-BART5 was driven by the strong H1 promoter (22). Significant reduction of luciferase activity induced by miR-BART5 indicated that the miR-BART5 target site in the PUMA 3′ UTR is functional (Fig. 1B). The specificity of miR-BART5-mediated silencing of PUMA was further supported by several controls in the experiment. First, miR-BART4, another miRNA encoded by EBV, did not show any inhibitory effect on PUMA 3′ UTR-dependent expression of luciferase gene. Second, miR-BART5 did not inhibit luciferase gene expression under the control of GAPDH sequences in cells receiving the pGL3-GAPDH.UTR reporter construct. Third, miR-BART5 suppressed reporter gene expression to similar magnitudes in cells receiving the pGL3-PUMA.UTR plasmid and the pGL3-BART5.UTR vector having 3′ UTR sequences perfectly complementary to miR-BART5. Finally, when the miR-BART5 target sequences in PUMA 3′ UTR were point mutated to disrupt complementarity to the seed region of miR-BART5 (Fig. 1B, top), the inhibition of luciferase expression by miR-BART5 was completely abolished.

A criticism of this experiment is that multiple copies of partial 3′ UTR sequence of PUMA were used. To address this issue, we constructed a plasmid in which a single copy of the entire 3′ UTR of PUMA controls the expression of luciferase reporter. When we repeated the reporter assay with this construct, luciferase activity was significantly decreased in cells expressing miR-BART5 (Fig. 1C). This effect was specific, as no such inhibition was observed when miR-BART4 was expressed. Likewise, specific suppression of luciferase activity under the control of a single copy of the entire 3′ UTR of PUMA was only seen in cells transfected with pre-miR-BART5, a chemically synthesized precursor miRNA (Fig. 1D). All these results consistently indicated specific targeting of PUMA 3′ UTR by miR-BART5.

Expression of miR-BART5 in EBV-infected epithelial cells

For miR-BART5 to fulfill a gene regulatory function, it has to be expressed in EBV-infected cells. Because miR-BARTs were thought to be expressed preferentially in EBV-infected epithelial cells (4, 7), we tested miR-BART5 expression in C666-1, an NPC cell line that constitutively harbors EBV (23). For comparison, we also examined HK1, another NPC cell line that does not carry EBV (24). In addition, we examined Akata, another NPC cell line, to which EBV was reintroduced by coculture with infected cells (25). Consistent with previous reports (4, 11), ample amount of miR-BART5 was found in C666-1 cells (Fig. 2A, lane 3). The expression level of miR-BART5 in C666-1 cells was comparable to that in HEK293 cells stably transfected with miR-BART5 expression vector (Fig. 2A, lane 5). As a control, miR-BART3-5p, another miRNA encoded by EBV, was also detected in C666-1 cells. Although no miR-BART5 was found in HK1 cells, the expression signal of miR-BART5 in HK1/EBV was visible after longer exposure of the blot (Fig. 2A, lanes 1 and 2).

Because miR-BARTs were also shown to be abundant in EBV-GC cells (7), the expression of miR-BART5 in AGS/BX1 was examined. AGS/BX1 cell line was established through infection of AGS cells with recombinant EBV virus carrying a GFP gene (26). We noted that miR-BART5 was expressed in AGS/BX1 but not in EBV-negative AGS cells (Fig. 2A, lane 7 compared with lane 6). In contrast, miR-BART5 was not expressed in B95–8 cells (Fig. 2B, lane 9; and Fig. S1, lane 21, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1) carrying a laboratory strain of EBV with a deletion in the miR-BART5 region (4). In addition, miR-BART5 was hardly found in other EBV-infected Burkitt’s lymphoma cell lines, Akata, Namalwa, and Raji (Fig. S1, lanes 18–20). Thus, miR-BART5 was preferentially expressed in EBV-infected NPC and GC cells.

We next extended our analysis of miR-BART5 expression to primary NPC tumor tissues and xenografts that had been verified to be positive for EBV-encoded small RNA (EBER). miR-BART5 was abundantly expressed in all NPC tumor
To verify the expression state of PUMA in human NPC, we determined the amounts of PUMA-\( \beta \) protein in 25 pairs of matched NPC and non-NPC samples. The NPC and non-NPC samples were collected from the same patient diagnosed with undifferentiated carcinoma, which is the most common histology in this region and associated with EBV (2). Consistent with results shown in Fig. 2 B and with a previous study (27), expression of viral markers EBER and BART in all NPC samples, as well as the absence of these markers in all non-NPC samples, were verified by RT-PCR (not depicted). Because of limited amount of sample, Northern blot analysis of miR-BART5 expression in the same sample was not possible. Among the 25 pairs of samples, a drop of PUMA-\( \beta \) protein expression was detected in \( \sim \)60% of the NPC tissues compared with their corresponding non-NPC tissues. Notably, PUMA-\( \beta \) expression was undetectable in many NPC samples. For example, in 12 representative pairs of NPC and non-NPC samples randomly selected (Fig. 3 B), PUMA-\( \beta \) was diminished in 7 NPC samples (samples QM1, QM7, QM8, QM9, QM10, QM11, and QM12), among which a complete loss of PUMA expression was seen in 5 samples (samples QM7, QM8, QM9, QM10, and QM12). Considered together with results shown in Fig. 1 and Fig. 2, we inferred that the expression of miR-BART5 was associated with severe inhibition of PUMA in undifferentiated NPC tissues.

Modulation of endogenous PUMA expression by miR-BART5

The above results provided the first experimental evidence for the regulation of PUMA expression by miR-BART5 of EBV. To test this idea more directly, we introduced pre-miR-BART5, the specificity of which had been verified in Fig. 1 D, into PUMA-expressing HeLa cells. When the miR-BART5 precursor RNA was expressed in the cells, substantial reduction in PUMA-\( \beta \) protein expression was observed, but this reduction was not seen in cells transfected with negative control precursor RNA (pre-miRNA-NC; Fig. 4 A, lanes 1 and 2). Likewise, a decline in PUMA-\( \beta \) expression was also observed when pre-miR-BART5 was overexpressed in HK1 cells (Fig. 4 A, lane 4 compared with lane 3). Because of difference in transfection efficiency (unpublished data), the magnitude of PUMA protein reduction in HK1 cells was not as great as in HeLa cells. To investigate the influence of miR-BART5 on the expression of PUMA mRNA, RT-PCR was performed with cells transfected with miR-BART5 expression vector. Although PUMA transcript was amply found in cells that expressed miR-BART5-3p, it was undetectable in miR-BART5-expressing cells (Fig. 4 B). Hence, regulation of PUMA protein expression by miR-BART5 was associated with decreased level of PUMA mRNA. This is consistent with the model in which miRNAs translationally repressed by miRNAs might be stored in the P-bodies and subsequently degraded (28, 29).

Enforced expression of miR-BART5 in HeLa and HK1 cells led to inhibition of PUMA expression (Fig. 4, A and B). In contrast, miR-BART5 was abundantly expressed in C666–1 and AGS/BX1 cells (Fig. 2 A). If miR-BART5 is an inhibitor
of PUMA expression, it should prevent the accumulation of PUMA protein in both C666-1 and AGS/BX1 cells. In other words, compromising the function of endogenous miR-BART5 in C666-1 cells should induce derepression of PUMA expression. Indeed, elevation of PUMA-α and PUMA-β proteins was observed in C666-1 cells when miR-BART5 was specifically inhibited with an anti-miR-BART5 oligonucleotide (Fig. 4 C). Consistent with this, luciferase reporter assay driven by PUMA 3′ UTR was also found to be increased in C666-1 cells transfected with anti-miR-BART5 (Fig. S3, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1). Likewise, an increase in the steady-state amount of PUMA-β protein was detected in AGS/BX1 cells transfected with anti-miR-BART5 (Fig. 4 D). These results corroborated the notion that the expression of PUMA was effectively repressed by miR-BART5 in EBV + epithelial cells.

miR-BART5 protects host cells from apoptosis

In the previous section, we presented several lines of evidence to support the regulation of PUMA by miR-BART5 in NPC cells. The importance of PUMA in mediating apoptosis prompted us to explore whether miR-BART5 inhibition of PUMA in NPC cells confers resistance to apoptosis. We compared the sensitivity of C666-1 and NP69 cells to adriamycin, a DNA-damaging agent that induces apoptosis. NP69 is an EBV- nasopharyngeal epithelial cell line, which is commonly used as a non-NPC counterpart of C666-1 (23, 30, 31). In line with our finding on the underexpression of PUMA in HK1/EBV cells (Fig. 3 A), the basal level of PUMA-β/H9252 protein in C666-1 cells was significantly lower than in NP69 cells (Fig. 5 A). In addition, treatment with adriamycin induced PUMA-β expression in NP69 cells, but no significant induction was seen in C666-1 cells. Consistent with this, a majority of poly (ADP-ribose) polymerase (PARP) protein was found to be cleaved in NP69 cells treated with 0.8 μg/ml or 1.2 μg/ml adriamycin, but the percentages of cleaved PARP were much smaller in C666-1 cells treated with the same concentrations of adriamycin (Fig. 5 A). The cleavage of PARP by caspase 3 facilitates cellular disassembly and serves as a sensitive marker of apoptosis (32). Thus, our results suggested that C666-1 cells expressing less PUMA-β were more resistant to apoptosis. A similar observation was also made with AGS/BX1 and HK1/EBV cells, which were less prone of PUMA expression, it should prevent the accumulation of PUMA protein in both C666-1 and AGS/BX1 cells. In other words, compromising the function of endogenous miR-BART5 in C666-1 cells should induce derepression of PUMA expression. Indeed, elevation of PUMA-α and PUMA-β proteins was observed in C666-1 cells when miR-BART5 was specifically inhibited with an anti-miR-BART5 oligonucleotide (Fig. 4 C). Consistent with this, luciferase reporter assay driven by PUMA 3′ UTR was also found to be increased in C666-1 cells transfected with anti-miR-BART5 (Fig. S3, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1). Likewise, an increase in the steady-state amount of PUMA-β protein was detected in AGS/BX1 cells transfected with anti-miR-BART5 (Fig. 4 D). These results corroborated the notion that the expression of PUMA was effectively repressed by miR-BART5 in EBV + epithelial cells.

miR-BART5 protects host cells from apoptosis

In the previous section, we presented several lines of evidence to support the regulation of PUMA by miR-BART5 in NPC cells. The importance of PUMA in mediating apoptosis prompted us to explore whether miR-BART5 inhibition of PUMA in NPC cells confers resistance to apoptosis. We compared the sensitivity of C666-1 and NP69 cells to adriamycin, a DNA-damaging agent that induces apoptosis. NP69 is an EBV- nasopharyngeal epithelial cell line, which is commonly used as a non-NPC counterpart of C666-1 (23, 30, 31). In line with our finding on the underexpression of PUMA in HK1/EBV cells (Fig. 3 A), the basal level of PUMA-β/H9252 protein in C666-1 cells was significantly lower than in NP69 cells (Fig. 5 A). In addition, treatment with adriamycin induced PUMA-β expression in NP69 cells, but no significant induction was seen in C666-1 cells. Consistent with this, a majority of poly (ADP-ribose) polymerase (PARP) protein was found to be cleaved in NP69 cells treated with 0.8 μg/ml or 1.2 μg/ml adriamycin, but the percentages of cleaved PARP were much smaller in C666-1 cells treated with the same concentrations of adriamycin (Fig. 5 A). The cleavage of PARP by caspase 3 facilitates cellular disassembly and serves as a sensitive marker of apoptosis (32). Thus, our results suggested that C666-1 cells expressing less PUMA-β were more resistant to apoptosis. A similar observation was also made with AGS/BX1 and HK1/EBV cells, which were less prone of PUMA expression, it should prevent the accumulation of PUMA protein in both C666-1 and AGS/BX1 cells. In other words, compromising the function of endogenous miR-BART5 in C666-1 cells should induce derepression of PUMA expression. Indeed, elevation of PUMA-α and PUMA-β proteins was observed in C666-1 cells when miR-BART5 was specifically inhibited with an anti-miR-BART5 oligonucleotide (Fig. 4 C). Consistent with this, luciferase reporter assay driven by PUMA 3′ UTR was also found to be increased in C666-1 cells transfected with anti-miR-BART5 (Fig. S3, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1). These results corroborated the notion that the expression of PUMA was effectively repressed by miR-BART5 in EBV + epithelial cells.

miR-BART5 protects host cells from apoptosis

In the previous section, we presented several lines of evidence to support the regulation of PUMA by miR-BART5 in NPC cells. The importance of PUMA in mediating apoptosis prompted us to explore whether miR-BART5 inhibition of PUMA in NPC cells confers resistance to apoptosis. We compared the sensitivity of C666-1 and NP69 cells to adriamycin, a DNA-damaging agent that induces apoptosis. NP69 is an EBV- nasopharyngeal epithelial cell line, which is commonly used as a non-NPC counterpart of C666-1 (23, 30, 31). In line with our finding on the underexpression of PUMA in HK1/EBV cells (Fig. 3 A), the basal level of PUMA-β/H9252 protein in C666-1 cells was significantly lower than in NP69 cells (Fig. 5 A). In addition, treatment with adriamycin induced PUMA-β expression in NP69 cells, but no significant induction was seen in C666-1 cells. Consistent with this, a majority of poly (ADP-ribose) polymerase (PARP) protein was found to be cleaved in NP69 cells treated with 0.8 μg/ml or 1.2 μg/ml adriamycin, but the percentages of cleaved PARP were much smaller in C666-1 cells treated with the same concentrations of adriamycin (Fig. 5 A). The cleavage of PARP by caspase 3 facilitates cellular disassembly and serves as a sensitive marker of apoptosis (32). Thus, our results suggested that C666-1 cells expressing less PUMA-β were more resistant to apoptosis. A similar observation was also made with AGS/BX1 and HK1/EBV cells, which were less prone
effectively inhibited by anti–miR-BART5 oligonucleotide (Fig. 4, C and D), we tested the influence of this miR-BART5 inhibitor on apoptosis of C666-1 and AGS/BX1 cells. Notably, transfection of C666-1 cells with anti–miR-BART5 oligonucleotide triggered apoptosis (Fig. 7 A and Fig. S5, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1). Additionally, anti–miR-BART5 oligonucleotide was able to enhance the proapoptotic effect of etoposide mildly leading to an ∼10% increase of TUNEL-positive apoptotic cells (Fig. 7 A). Plausibly, both anti–miR-BART5 oligonucleotide and etoposide exert their proapoptotic effects by inducing the expression of PUMA.

To verify that the effect of anti–miR-BART5 is indeed mediated through PUMA, we made use of small interfering RNA against PUMA (siPUMA), a validated siRNA targeting PUMA transcripts. As a first step, the effectiveness of siPUMA to apoptosis than their respective parental cells (Fig. 5 B, lane 4 compared with lane 2 and lane 8 compared with lane 6). Thus, miR-BART5–expressing cells (C666-1, AGS/BX1 and HK1/EBV) are less susceptible to apoptosis–inducing drugs.

Interestingly, we found that the resistance to apoptosis occurred only in C666-1 cells treated with low–dose adriamycin (<1.2 μg/ml). Apoptosis was induced when the concentration of adriamycin was increased to 1.5 μg/ml or higher. Likewise, C666-1 cells treated with 80 μM etoposide also underwent apoptosis (Fig. 6). The manifestation of apoptosis in treated C666-1 cells was indicated by PARP cleavage (Fig. 6 A) and by terminal deoxynucleotidyl transferase–mediated dUTP-biotin nick end labeling (TUNEL) assay, which measures DNA fragmentation (Fig. 6 B and Fig. S4, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1). To investigate the underlying mechanism of apoptosis, we determined the expression profile of p53 and PUMA-β. Interestingly, both p53 and PUMA-β were induced significantly by high–dose adriamycin and etoposide (Fig. 6 A). Collectively, our results are compatible with the notion that the steady–state amount of PUMA dictates cellular sensitivity to proapoptotic agents. According to this model, when PUMA expression in C666-1 cells was effectively blocked by miR-BART5, apoptosis was prevented (Fig. 5). However, if the inhibitory effect of miR-BART5 was overcome by high–dose proapoptotic agents, apoptosis was triggered (Fig. 6).

To further strengthen this model, we asked whether inhibition of miR-BART5 by another means would also induce apoptosis. Because miR-BART5 can be specifically and effectively inhibited by anti–miR-BART5 oligonucleotide (Fig. 4, C and D), we tested the influence of this miR-BART5 inhibitor on apoptosis of C666-1 and AGS/BX1 cells. Notably, transfection of C666-1 cells with anti–miR-BART5 oligonucleotide triggered apoptosis (Fig. 7 A and Fig. S5, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1). Additionally, anti–miR-BART5 oligonucleotide was able to enhance the proapoptotic effect of etoposide mildly leading to an ∼10% increase of TUNEL-positive apoptotic cells (Fig. 7 A). Plausibly, both anti–miR-BART5 oligonucleotide and etoposide exert their proapoptotic effects by inducing the expression of PUMA.

To verify that the effect of anti–miR-BART5 is indeed mediated through PUMA, we made use of small interfering RNA against PUMA (siPUMA), a validated siRNA targeting PUMA transcripts. As a first step, the effectiveness of siPUMA to apoptosis than their respective parental cells (Fig. 5 B, lane 4 compared with lane 2 and lane 8 compared with lane 6). Thus, miR-BART5–expressing cells (C666-1, AGS/BX1 and HK1/EBV) are less susceptible to apoptosis–inducing drugs.

Interestingly, we found that the resistance to apoptosis occurred only in C666-1 cells treated with low–dose adriamycin (<1.2 μg/ml). Apoptosis was induced when the concentration of adriamycin was increased to 1.5 μg/ml or higher. Likewise, C666-1 cells treated with 80 μM etoposide also underwent apoptosis (Fig. 6). The manifestation of apoptosis in treated C666-1 cells was indicated by PARP cleavage (Fig. 6 A) and by terminal deoxynucleotidyl transferase–mediated dUTP-biotin nick end labeling (TUNEL) assay, which measures DNA fragmentation (Fig. 6 B and Fig. S4, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1). To investigate the underlying mechanism of apoptosis, we determined the expression profile of p53 and PUMA-β. Interestingly, both p53 and PUMA-β were induced significantly by high–dose adriamycin and etoposide (Fig. 6 A). Collectively, our results are compatible with the notion that the steady–state amount of PUMA dictates cellular sensitivity to proapoptotic agents. According to this model, when PUMA expression in C666-1 cells was effectively blocked by miR-BART5, apoptosis was prevented (Fig. 5). However, if the inhibitory effect of miR-BART5 was overcome by high–dose proapoptotic agents, apoptosis was triggered (Fig. 6).

To further strengthen this model, we asked whether inhibition of miR-BART5 by another means would also induce apoptosis. Because miR-BART5 can be specifically and effectively inhibited by anti–miR-BART5 oligonucleotide (Fig. 4, C and D), we tested the influence of this miR-BART5 inhibitor on apoptosis of C666-1 and AGS/BX1 cells. Notably, transfection of C666-1 cells with anti–miR-BART5 oligonucleotide triggered apoptosis (Fig. 7 A and Fig. S5, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1). Additionally, anti–miR-BART5 oligonucleotide was able to enhance the proapoptotic effect of etoposide mildly leading to an ∼10% increase of TUNEL-positive apoptotic cells (Fig. 7 A). Plausibly, both anti–miR-BART5 oligonucleotide and etoposide exert their proapoptotic effects by inducing the expression of PUMA.

To verify that the effect of anti–miR-BART5 is indeed mediated through PUMA, we made use of small interfering RNA against PUMA (siPUMA), a validated siRNA targeting PUMA transcripts. As a first step, the effectiveness of siPUMA to apoptosis than their respective parental cells (Fig. 5 B, lane 4 compared with lane 2 and lane 8 compared with lane 6). Thus, miR-BART5–expressing cells (C666-1, AGS/BX1 and HK1/EBV) are less susceptible to apoptosis–inducing drugs.

Interestingly, we found that the resistance to apoptosis occurred only in C666-1 cells treated with low–dose adriamycin (<1.2 μg/ml). Apoptosis was induced when the concentration of adriamycin was increased to 1.5 μg/ml or higher. Likewise, C666-1 cells treated with 80 μM etoposide also underwent apoptosis (Fig. 6). The manifestation of apoptosis in treated C666-1 cells was indicated by PARP cleavage (Fig. 6 A) and by terminal deoxynucleotidyl transferase–mediated dUTP-biotin nick end labeling (TUNEL) assay, which measures DNA fragmentation (Fig. 6 B and Fig. S4, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1). To investigate the underlying mechanism of apoptosis, we determined the expression profile of p53 and PUMA-β. Interestingly, both p53 and PUMA-β were induced significantly by high–dose adriamycin and etoposide (Fig. 6 A). Collectively, our results are compatible with the notion that the steady–state amount of PUMA dictates cellular sensitivity to proapoptotic agents. According to this model, when PUMA expression in C666-1 cells was effectively blocked by miR-BART5, apoptosis was prevented (Fig. 5). However, if the inhibitory effect of miR-BART5 was overcome by high–dose proapoptotic agents, apoptosis was triggered (Fig. 6).

To further strengthen this model, we asked whether inhibition of miR-BART5 by another means would also induce apoptosis. Because miR-BART5 can be specifically and
was confirmed by Western blot analysis of PUMA-β (Fig. 7 B). We then cotransfected both anti–miR-BART5 and siPUMA into C666-1 cells and assessed the impact on apoptosis. A partial but significant suppression of anti–miR-BART5–dependent proapoptotic activity by siPUMA (Fig. 7 C) provided further support to our model.

Additionally, transfection of AGS/BX1 cells with anti–miR-BART5 also induced apoptosis, but to a lesser extent (Fig. S6, available at http://www.jem.org/cgi/content/full/jem.20072581/DC1). This weaker effect might be ascribed to a higher basal level of apoptosis in anti–miRNA-NC–transfected AGS/BX1 cells, which had been selected with G418. Collectively, our results consistently demonstrated that miR-BART5 protects host epithelial cells from apoptosis.

**DISCUSSION**

In this study, we provided the validation of a cellular target of EBV miRNA and characterized the antiapoptotic function of an EBV miRNA. Three lines of evidence were presented to support the regulation of PUMA protein expression by miR-BART5 in EBV-infected epithelial cells. First, an miR-BART5 target site in the 3′ UTR of PUMA transcript was identified and validated (Fig. 1 and Fig. S2). Second, abundant expression of miR–BART5 in NPC cells (Fig. 2 and Fig. S1) correlated with significant underexpression of PUMA in ~60% of NPC tissues (Fig. 3). Third, manipulation of miR–BART5 expression in NPC cells and an miR–BART5 producing carcinoma cells from another origin (EBV-GC cells) by overexpression and depletion with an oligonucleotide inhibitor resulted in repression and derepression of PUMA expression, respectively (Fig. 4). More importantly, miR–BART5 was shown to have antiapoptotic activity in both NPC and EBV-GC cells. Although EBV+ NPC and EBV-GC cells were found to be less susceptible to apoptosis (Fig. 5), induced expression of endogenous PUMA by either pharmacological agent or anti–miR–BART5 oligonucleotide triggered apoptotic death of these cells (Figs. 5–7 and S3–S5). Our findings suggest a new mechanism for the survival of EBV-infected epithelial cells in which miR–BART5 targets PUMA to confer resistance to apoptosis. This work has important implications not only in EBV biology and pathogenesis, but also in the development of new anti-EBV and anticancer agents.

Herpesviruses encode various miRNAs to regulate viral replication and to counteract host defense such as apoptosis and immunity (33). For example, CMV exploits miR-UL112-1 to evade immune surveillance by suppressing MICB gene (34) and to inhibit expression of the major immediate-early genes (35). In EBV, >20 viral miRNAs are categorized into two main groups, namely miR-BHRF1 and miR-BARTs (3–5). Although some of the EBV miRNAs are thought to modulate viral gene expression by targeting BALF5 and LMP1 (3, 11), miR-BHRF1-3 has been proposed to repress expression of a chemokine named CXCL1-1, which attracts T cells in response to interferons (10). It is noteworthy that other viral genes in the BHRF1 and BART regions also have regulatory function in apoptosis and cell signaling. As such, BHRF1 gene encodes an antiapoptotic Bcl-2 homologue that enhances cell survival (36), whereas several protein products derived from BART mRNAs can modulate Notch signaling and RACK1–orchestrated activities (37, 38). miR-BART5 was derived from an intron of BART transcript. Although our findings on miR-BART5 reveal another level of complexity in the functions of BART transcripts during EBV infection, the PUMA-suppressing and antiapoptotic properties of miR-BART5 are generally consistent with existing knowledge on BARTs and EBV miRNAs. Our demonstration of the antiapoptotic function of miR-BART5 from EBV provides the first example for viral modulation of apoptosis through an miRNA. Plausibly, different viral miRNAs might target different cellular proapoptotic proteins to promote host cell survival.

Although PUMA has the ability to mediate p53-independent apoptosis, it remains an immediate and important downstream target of p53 (12–17). p53 and PUMA are master regulators of cellular growth and apoptosis. In view of the recent finding that miR-34s are direct transcriptional targets of p53, the link between p53 and miRNAs is closer than expected (39). However, one missing piece in the p53-miRNA puzzle is the regulation of p53 and p53 targets by miRNAs. In this perspective, our findings on the modulation of PUMA expression by miR–BART5 add a new dimension to our knowledge of p53 and miRNA. It remains to be elucidated whether p53 and PUMA might be targeted by other viral and cellular miRNAs.

Notably, Kaposi’s sarcoma–associated herpesvirus miR-K12-11 is an orthologue of cellular miR-155 (40, 41). In addition, miR-BART5 of EBV shares significant seed homology with cellular miR-18a and miR-18b (42). Although cellular miRNAs that target PUMA have not been identified, we cannot rule out the possibility that miR-BART5 and a cellular miRNA might target the same 3′ UTR sequence of PUMA mRNA. Hence, additional experiments are required to clarify whether the anti–miR–BART5 oligonucleotide used in our study might also affect unidentified cellular miRNAs that regulate PUMA expression.

The modulation of PUMA by miR-BART5 was not surprising. In NPC, p53 is rarely mutated (43) but commonly activated likely through LMP1 (44). Thus, EBV has to develop counter measures against p53 activation of PUMA to persist within the host cell. As demonstrated in our study, EBV can express ample amount of miR-BART5 to down-regulate the expression of proapoptotic PUMA in NPC and GC cells latently infected by EBV. This might explain the particularly high expression of miR-BART5 in epithelial cancer cells when compared with EBV-positive lymphoma cells. It is also noteworthy that the underexpression of PUMA was observed only in ~60% of the BART+ NPC tissue samples (Fig. 3). This raises the possibility that PUMA expression might be governed by more than one mechanism during EBV infection and carcinogenesis.

Our work has derived one new mechanism for EBV modulation of apoptosis. Based on this mechanism, new strategies can be devised to develop diagnostic tools and therapeutic agents. For example, the detection of miR-BART5...
could be useful in the diagnosis of NPC and EBV-GC. In addition, miR-BART5 is a potential therapeutic target in NPC, EBV-GC, and other EBV-associated epithelial malignancies. The use of anti-miR-BART5 oligonucleotide inhibitor to specifically induce apoptosis in epithelial cancer cells may prove useful in anti-EBV and anti-cancer therapy.

MATERIALS AND METHODS

Target prediction. miRanda (18) and RNAhybrid (20) were used to predict the potential targets of EBV miRNAs. Human 3′ UTR sequences were retrieved using BioMart (http://wwwensembl.org/Multi/martview) and subsequently fed into miRanda for prediction, with an energy threshold of −20 kcal/mol and a cutoff score of 120 to increase the stringency. Potential targets ranked within the top 50 (see Table S1) for a list of potential targets of miR-BART5 predicted by miRanda were then reanalyzed using RNAhybrid. Cross species conservation was also assessed using University of California Santa Cruz Human BLAT (http://genome.ucsc.edu/cgi-bin/hgBlat?command=start). Potential target sites with a minimum free energy of <−30 kcal/mol, as predicted by RNAhybrid, were shortlisted for functional screening with luciferase reporter assays.

For prediction of miR-BART5 targets, nine potential targets were obtained after analysis by miRanda and RNAhybrid. Although PUMA was ranked 43rd in the list of targets predicted by miRanda, it was selected for validation by reporter assay because the target site was predicted to have a minimum free energy of −30.7 kcal/mol (Table S1). Among all potential target sites verified by reporter assay, PUMA was the only one that was suppressed by miR-BART5 (Table S1).

Cell culture, transfection, and reporter assay. HeLa and HEK293 cell lines; human NPC cell lines C666-1, HK1, and HK1/EBV; human EBV-GC cell line AG826/BX1 and its parental line AG826 (provided by H. Chen and B. Wong, University of Hong Kong, Pokfulam, Hong Kong); human nasopharyngeal cell lines NP69 and NP460; and EBV-infected Burkitt’s lymphoma cell lines Akata, B95-8, Namalwa, and Raji were cultured and transfected as previously described (25, 26, 30, 45–49). NP69 and NP460 are epithelial cell lines immortalized with SV40 T antigen and are commonly regarded as the non-NPC counterpart of C666-1 (25, 30, 31).

Transfection of cells with 100 nM of pre-miR mRNA precursor (Ambion), 150 nM of anti-miR mRNA inhibitor (Ambion), or 100 nM siRNA against PUMA mRNA (siPUMA; Thermo Fisher Scientific) was performed using Lipofectamine 2000 (Invitrogen). Pre-miR mRNA precursors are small chemically modified double-stranded RNA molecules designed to mimic endogenous mature miRNAs. Anti-miR mRNA inhibitors are chemically modified single-stranded nucleic acids designed to specifically bind to and inhibit the activity of endogenous miRNAs. siPUMA is an siRNA that targets nt 715–733 of PUMA mRNA (GenBank NM_014417). Pre-miR, anti-miR, and siPUMA oligonucleotides are ready-to-use reagents with validated activity and specificity.

Dual luciferase reporter assay was performed as previously described (45, 50) using Dual-Luciferase reporter assay system (Promega). The readouts of luciferase activity were taken in an LB 96V microplate luminometer (EGG&G Berthold).

Plasmid construction. miR-BART expression vectors (pmiR-BART) were made by inserting miR-BARTs into pSuper vector (provided by R. Agani, Netherlands Cancer Institute, Amsterdam, Netherlands) (22). miR-BARTs were PCR-amplified using genomic DNA of C666-1 cells as template. Primers for amplification of miR-BART5 (nt 946–1196, available at GenBank/EMBL/DDBJ under accession no. EF102892) were 5′-GGAAAA-TCTATAGAGACACAAAGCAGTGGCAGCC-3′ (forward) and 5′-CCCC- AAGCTTCCAAAAACAGAGCACAACCCACTGTATC-3′ (reverse). Firefly luciferase reporter plasmid pGL3-PUMA/UTR bearing four copies of the miR-BART5 target site found in 3′ UTR of PUMA was constructed by inserting PUMA sequences (nt 1331–1460, available at GenBank/DDBJ under accession no. NM_014417) into the XbaI site of pGL3-Control, which is located immediately after the stop codon of the luciferase gene (Promega). As controls, luciferase reporter plasmid pGL3-GAPDH/UTR contains four copies of irrelevant sequences derived from GAPDH, whereas pGL3-BART5.UTR carries four repeats of sequences perfectly complementary to miR-BART5. pGL3-mutPUMA.UTR was derived from pGL3-PUMA-UTR, with the change of 4 nt introduced with QuikChange site-directed mutagenesis kit (Stratagene). As for reporter plasmid pGL3-PUMA-FL.UTR, a single copy of the entire 3′ UTR of PUMA was cloned by PCR amplification of nt 878–1695 in PUMA gene (available at GenBank/EMBL/DDBJ under accession no. NM_014417) and then inserted into the XbaI site of pGL3-Control. In plasmid pGL3-PUMA-FL.UTR, the reverse sequence of PUMA 3′ UTR was inserted. PUMA cDNA was supplied by B. Vogelstein (Johns Hopkins University, Baltimore, MD) and K. Vousden (the Beatson Institute for Cancer Research, Glasgow, UK).

RNA analysis. 50 μg of total RNA extracted from cultured cells using Trizol reagent (Invitrogen) was subjected to Northern blotting as detailed elsewhere (45). cDNA was also synthesized from Trizol-extracted RNA with Thermoscript reagents (Invitrogen). Semiquantitative PCR was performed with 2 μl of the synthesized cDNA using the following thermal cycling profile: 94°C for 5 min, 30 cycles of amplification (94°C for 1 min, 55°C for 30 s, and 72°C for 30 s), and 72°C for 7 min.

Tumor samples. For Northern blot analysis, NPC tumor biopsies voluntarily donated by 15 individuals were obtained from the Department of Anatomical and Cellular Pathology at the Prince of Wales Hospital (Chinese University of Hong Kong). Human experiments were approved by Joint Clinical Research Ethics Committee of the Chinese University of Hong Kong and Hospital Authority New Territories East Cluster. 75% of the NPC patients were male, whereas two patients were males in the control group. The age of subjects ranged from 25 to 71 yr old. The NPC patients were diagnosed with primary NPC of stages 1–4 (51), except for one patient who had local nasopharyngeal recurrent of NPC. For Western blot analysis, ~30 pairs of matched NPC and non-NPC samples of the same individual were obtained from Queen Mary Hospital (University of Hong Kong) with the consent of patients for tissue donation. Human experiments were approved by Institutional Review Board of the University of Hong Kong and Hospital Authority Hong Kong West Cluster. 65% of the patients were male. The age of patients ranged from 41 to 68 yr old. Biopsies were taken and endoscopic assessment of the nasopharynx was performed before the start of treatment. Matched samples were taken from the tumor and the grossly unaffected side of nasopharynx for study. All tumor specimens were histologically evaluated to be undifferentiated carcinoma, except for one patient who had poorly differentiated squamous carcinoma. The patients were diagnosed to have primary NPC of stages 1–4 (51). All samples were snap frozen in liquid nitrogen and stored at −80°C until lyzed with RIPA for Western blot analysis.

Generally consistent with previous findings (27), all NPC samples tested for PUMA expression were positive for EBER and BART transcripts by RT-PCR, whereas all non-NPC tissues were negative for EBER or BART.

Western blotting. RIPA buffer (50 mM Tris–Cl, pH 7.4, 150 mM NaCl, 1% Triton X-100, 0.1% SDS, and 1% sodium deoxycholate) was used to lyse the cells for SDS-PAGE analysis (45, 50). The primary antibodies included a rabbit monoclonal against PUMA (Abcam), a mouse monoclonal against p53 (Santa Cruz Biotechnology, Inc.), a rabbit polyclonal against PARP (Cell Signaling Technology), and a mouse monoclonal antibody against α-tubulin or β-actin (Sigma–Aldrich). The anti-PUMA antibody preferentially reacts with PUMA-β, but the PUMA-α isoform can also be detected in some cells.

Apoptosis assays. PARP cleavage in apoptotic cells was monitored by Western blotting. TUNEL assay was performed by confocal microscopy with fluorescein-based reagents (in situ cell death detection kit; Roche).

Online supplemental material. Fig. S1 shows the expression of miR-BART5 in EBV-infected cells and tissues. Fig. S2 presents the comparison
of PUMA 3' UTR activity in HK1 and HK1/EBV cells. Fig. S3 demonstrates the influence of anti-miR-BART5 on PUMA 3' UTR activity in C666-1 cells. Fig. S4 and Fig. S5 are representative images that demonstrate the induction of apoptosis in C666-1 cells through activation of PUMA expression and inhibition of miR-BART5, respectively. Fig. S6 shows the induction of apoptosis in AGS/BX1 cells through inhibition of miR-BART5. Table S1 lists the potential targets of miR-BART5 predicted by miRanda and RNAhybrid. Online supplemental material is available at http://www.jem.org/cgi/content/full/jem.200725881/DC1.

We thank Reuven Agami, Bert Vogelstein, and Karen Vousden for gifts of plasmid; Hongqin Chen and Benjamin Wong for providing AGS and AGS/BX1 cells; Annie Cheung, Wilson Ching, Xin-Yuan Guan, Kwok-Wai Lo, Randy Poon, and Qian Tao for comments and suggestions; and Abel Chun, James Ng, and Vincent Tang for critical reading of the manuscript.
