APPROXIMATION OF A FIXED POINT OF A $\phi$-STRONGLY PSEUDOCONTRACTIVE MAPPING IN A BANACH SPACE

HIROKO MANAKA TAMURA

ABSTRACT. In the present paper, we show the stability result of the following unified iterative scheme

$$x_{n+1} = t_n v_n + (1 - t_n) x_n + u_n$$

for a given sequence $\{v_n\}$ in a Banach space $X$ and a $\phi$-strongly pseudocontractive mapping $T$ with a coefficient sequence $\{t_n\}$ in $[0,1]$ and an error term sequence $\{u_n\}$ in $X$. This stability result implies a convergence theorem of Mann, Ishikawa and Stević's iterations. We also try to show convergence rate estimates to a fixed point of $T$.

1. INTRODUCTION

Let $X$ be an arbitrary Banach space and let $T : X \rightarrow X$ be a nonlinear mapping such that the set $F(T)$ of fixed points of $T$ is nonempty. In the last four decades, numerous papers have been published on the iterative approximation of fixed points of nonlinear mappings $T$ in Banach spaces. Let $J$ denote the normalized duality mapping from $X$ into $2^{X^*}$ given by

$$J(x) = \{ f \in X^* : \langle x, f \rangle = ||x||^2 = ||f||^2 \},$$

where $X^*$ denotes the dual space of $X$ and $\langle \cdot, \cdot \rangle$ denotes the duality pairing. A mapping $T : D(T) \subset X \rightarrow X$ is called a strong pseudocontraction if there exists $t > 1$ such that for all $x, y \in D(T)$, there is $j(x - y) \in J(x - y)$ satisfying

$$\langle Tx - Ty, j(x - y) \rangle \leq \frac{1}{t} ||x - y||^2.$$

Let $\phi : [0, \infty) \rightarrow [0, \infty)$ be a strictly increasing function with $\phi(0) = 0$. A mapping $T : D(T) \subset X \rightarrow X$ is called $\phi$-strongly pseudocontractive if for all $x, y \in D(T)$ there exists $j(x - y) \in J(x - y)$ such that

$$\langle Tx - Ty, j(x - y) \rangle \leq ||x - y||^2 - \phi(||x - y||) ||x - y||.$$

We call a $\phi$-strongly pseudocontractive mapping a $\phi$-strong pseudocontraction. The class of strong pseudocontractions and the class of $\phi$-strong pseudocontractions have been studied extensively by several authors (see [1], [6], [8], [14]). It was shown in [14] that the class of strong pseudocontractions is a proper subset of the class of $\phi$-strong pseudocontractions. It is well-known that if $T : X \rightarrow X$ is continuous and strongly pseudocontractive, then $T$ has a unique fixed point (see [18]). Let

\begin{itemize}
  \item [1991 Mathematics Subject Classification.] Primary 47H06, 47H09, 47H17, 47J05, 47J25.
  \item [Key words and phrases.] Stability, Iterative scheme, $\phi$-strongly pseudocontraction, Fixed point, Convergence theorem, Mann iteration, Ishikawa iteration, Stević iteration, Convergence rate estimate.
\end{itemize}
$C$ be a closed convex subset of $X$. If $T : C \rightarrow C$ is continuous and $\phi$-strongly pseudocontractive, then $T$ has a unique fixed point (see [6], [7]).

A mapping $f(T, \cdot) : X \rightarrow X$ is said to be an iterative scheme when $f(T, \cdot)$ is considered as a procedure, involving $T$, which yields a sequence of points $\{x_n\} \subset X$ defined by $x_{n+1} = f(T, x_n)$ for $n \geq 0$, where $x_0 \in X$ is given. Suppose that the sequence $\{x_n\}$ converges strongly to a $p \in F(T)$, and then it is denoted by $x_n \rightarrow p \in F(T)$. Let $\{y_n\}$ be an arbitrary sequence in $X$. If $\lim_{n \rightarrow \infty} \|y_{n+1} - f(T, y_n)\| = 0$ implies $y_n \rightarrow p \in F(T)$, then an iterative scheme $f(T, \cdot)$ is said to be $T$-stable or stable with respect to $T$ (see [3]). We say that an iterative scheme $f(T, \cdot)$ is almost $T$-stable or almost stable with respect to $T$ if $\sum_{n=1}^{\infty} \|y_{n+1} - f(T, y_n)\| < \infty$ implies $y_n \rightarrow p \in F(T)$. (cf. [17], [22]). Clearly, an iterative scheme $f(T, \cdot)$ which is $T$-stable is almost $T$-stable. In [17] Osilike gave an example showing that an iterative scheme which is almost $T$-stable may fail to be $T$-stable. In [3], Harder and Hicks pointed out the importance of stability of iteration schemes from the view point of practical use of iterations, and gave some results for the stability of iteration schemes. Recently, the stability of iterative scheme for nonlinear mappings was investigated by several authors (cf. [15], [16], [17], [19], [20], [21], [22], [23], [24]).

In this paper, first we show a stability result of the following iteration scheme $f(T, v_n, \cdot)$ involving a $\phi$-strong pseudocontraction $T$ and a sequence $\{u_n\}$ in $X$:

\[
\begin{aligned}
x_0 & \in X, \\
x_{n+1} &= f(T, v_n, x_n) \\
&= t_n T v_n + (1-t_n) x_n + u_n,
\end{aligned}
\]

(1.1)

where $\{t_n\}$ and $\{u_n\}$ are a coefficient sequence in $[0, 1]$ and an error term sequence in $X$, respectively. This iteration scheme gives the Mann iteration as a special case when $v_n = x_n, (n \geq 0)$ ([13]). Moreover we show that this stability result implies the stability of an iterative scheme for a family of $k$ selfmappings $T_1, T_2, \ldots, T_k$ with $k$ coefficient sequences $\{t_{n}^{(j)}\}$ and $k$ error term sequences $\{u_{n}^{(j)}\}, (j = 1, \ldots, k)$ such as

\[
\begin{aligned}
x_0 & \in X, \\
x_{n+1} &= f(T_1, T_2, \ldots, T_k, x_n) \\
&= t_{n}^{(1)} T_1 x_n^{(1)} + \cdots + (1-t_{n}^{(k)}) x_n + u_{n}^{(k)},
\end{aligned}
\]

(1.2)

where

\[
x_{n}^{(1)} = t_{n}^{(2)} T_2 x_{n}^{(2)} + \cdots + (1-t_{n}^{(k)}) x_n + u_{n}^{(k)},
\]

\[
\vdots
\]

\[
x_{n}^{(k-1)} = t_{n}^{(k)} T_k x_n + (1-t_{n}^{(k)}) x_n + u_{n}^{(k)},
\]

and

\[
x_{n}^{(k)} = x_n.
\]

This iteration generalizes the Mann, Ishikawa, Das & Debata and Stević iterations, and we obtain them as special cases when we put $T_1 = T, T_1 = T_2 = T, T_1 \neq T_2, \text{and} T_1 = T_2 = \cdots = T_k = T$, respectively. (See [2], [4], [13], [22], [25], etc.) Our iteration defined by (1.1) is a unified approach for these iterations, when we put $v_n = x_{n}^{(1)}$. With respect to the stability results of Mann and Ishikawa iterations, there are many results by several authors (see [11], [15], [16], [17], [21], [24]). Osilike gave the result of Mann and Ishikawa iterations for a $\phi$-strong pseudocontraction in [17],
and Stević generalized the stability result of Osilike in [24]. The unified approach of (1.1) gives a natural generalization of Stević's result and a strong convergence theorem for iterations defined by (1.2). Secondary we try to show how fast the iterative sequence converges to a fixed point. We give the convergence rate estimates for Mann iteration involving a Lipschitz continuous $\phi$-strong pseudocontraction $T$ on a closed convex subset $C$ in an arbitrary Banach space $X$.

2. PRELIMINARIES

We shall give some lemmata which are needed to present our statements and to prove the main results.

Lemma 1. [9] Let $\{a_n\}, \{b_n\}$ and $\{c_n\}$ be three non-negative real number sequences satisfying the difference inequality

\[
a_{n+1} \leq (1 - t_n)a_n + b_n + c_n.
\]

Suppose

\[
\{t_n\} \subseteq [0, 1], \quad \sum_{n=1}^{\infty} t_n = \infty, \quad b_n = o(1), \quad \text{and} \quad \sum_{n=1}^{\infty} c_n < \infty.
\]

Then

\[
\lim_{n \to \infty} a_n = 0.
\]

Lemma 2. [24] Let $\{a_n\}, \{b_n\}$ and $\{c_n\}$ be three non-negative real number sequences satisfying the difference inequality (2.1). Suppose $\{t_n\} \subseteq [0, 1]$, $\sum_{n=1}^{\infty} t_n = \infty$, $b_n = O(t_n)$, and $\sum_{n=1}^{\infty} c_n < \infty$. Then $\{a_n\}$ is bounded.

The following lemma plays an important role in the proof of the main theorem.

Lemma 3. [24] Let $\{a_n\}, \{b_n\}, \{t_n\}, \{\delta_n\}$ and $\{\rho_n\}$ be non-negative real number sequences satisfying the following conditions (a) - (g):

(a) $a_{n+1} \leq \left(1 - t_n \frac{f_1(b_n)}{f_2(b_n)}\right)a_n + t_n\delta_n + \rho_n$,

where $f_1$ and $f_2$ are non-negative increasing functions on $[0, \infty)$, and $f_2(0) > 0$,

(b) $\{t_n\} \subset [0, 1]$ and $\lim_{n \to \infty} t_n = 0$,

(c) $\lim_{n \to \infty} \delta_n = 0$,

(d) $\sum_{n=1}^{\infty} \rho_n < \infty$,

(e) $\{a_n\}$ is bounded and $\liminf_{n \to \infty} a_n = 0$,

(f) $\lim_{n \to \infty} (a_{n+1} - a_n) = 0$,

(g) $\lim_{n \to \infty} (a_n - b_n) = 0$.

Then

\[
\lim_{n \to \infty} a_n = 0.
\]
Lemma 4. (cf. [5]) Let $X$ be a Banach space, and let $T$ be $\phi$-strongly pseudocontractive. For any $x, y \in X$ and $r > 0$,

$$||x - y|| \leq ||x - y + r((I - T - \gamma(x, y))x - (I - T - \gamma(x, y))y)||,$$

where

$$\gamma(x, y) = \frac{\phi(||x - y||)}{1 + \phi(||x - y||) + ||x - y||}.$$

The following lemma can be proved using Lemma 4, similar to the method used for a pseudocontraction (cf. [10], [24]).

Lemma 5. Let $T$ be $\phi$-strongly pseudocontractive on $X$, and let $y^*$ be defined by

$$y^* = tTv + (1 - t)y + u,$$

for $y, u, v \in X$, and $t \in [0, 1]$. Suppose $p \in F(T) \neq \emptyset$. Then

$$||y^* - p|| \leq \frac{1 + t(1 - \gamma^*)}{1 + t} ||y - p|| + \frac{t^2(2 - \gamma^*)}{1 + t} ||y - Tv||$$

$$+ \frac{t}{1 + t} ||Ty^* - Tv|| + \frac{1 + t(2 - \gamma^*)}{1 + t} ||u||,$$

where

$$\gamma^* = \gamma(y^*, p) = \frac{\phi(||y^* - p||)}{1 + \phi(||y^* - p||) + ||y^* - p||}.$$

3. Stability and Strong Convergence Theorem

We shall show a stability result and a strong convergence theorem.

Theorem 1. [26] Let $X$ be an arbitrary Banach space and let $T$ be a uniformly continuous and $\phi$-strongly pseudocontractive selfmapping on $X$ with a bounded range. For a sequence $\{v_n\}$ in $X$, let an iterative scheme $f(T, v_n, \cdot)$ with a coefficient sequence $\{t_n\}$ in $[0, 1]$ and an error term sequence $\{u_n\}$ in $X$ be defined by (1.1). Suppose that $\{t_n\}$ and $\{u_n\}$ satisfy the following conditions:

(i) $\sum_{n=1}^{\infty} ||u_n|| < \infty$,

(ii) $\sum_{n=1}^{\infty} t_n = \infty$,

(iii) $\lim_{n \to \infty} t_n = 0$.

Then the following statements hold.

(I) If $\{y_n\}$ in $X$ satisfies

$$||y_n - v_n|| \to 0 \ (n \to \infty) \ \text{and} \ \sum_{n=1}^{\infty} ||y_{n+1} - f(T, v_n, y_n)|| < \infty,$$

then $y_n \to p \in F(T)$.

(II) If $w_n \to p \in F(T)$, then

$$||w_{n+1} - f(T, v_n, w_n)|| \to 0 \ (n \to \infty).$$
PROOF. (I) Suppose \( \{y_n\} \) in \( X \) satisfies
\[
\|y_n - v_n\| \to 0 \quad (n \to \infty) \quad \text{and} \quad \sum_{n=1}^{\infty} \|y_{n+1} - f(T, v_n, y_n)\| < \infty.
\]
Let \( \varepsilon_n \) be \( \|y_{n+1} - f(T, v_n, y_n)\| \) for \( n \geq 1 \), then
\[
\|y_{n+1} - p\| \leq \varepsilon_n + \|t_n T v_n + (1 - t_n) y_n + u_n - p\|
\leq \varepsilon_n + t_n \|Tv_n - p\| + (1 - t_n) \|y_n - p\| + \|u_n\|.
\]
Since \( T \) has a bounded range, there exists \( M \) such that \( \sup_n \|Tv_n - p\| = M < \infty \).
Thus the above inequality implies
\[
\|y_{n+1} - p\| \leq (1 - t_n) \|y_n - p\| + t_n M (\varepsilon_n + \|u_n\|).
\]
Setting \( a_n = \|y_n - p\|, b_n = t_n M, \) and \( c_n = \varepsilon_n + \|u_n\| \), Lemma 2 gives the boundedness of \( \{y_n\} \). Let \( M_0 \) denote \( \max\{M, \sup_n \|y_n - p\|\} \). Let \( y_{n+1}^* = f(T, v_n, y_n) \).
From Lemma 5, putting \( \gamma_n = \gamma(y_{n+1}^*, p) \), we have an estimate of \( \|y_{n+1} - p\| \) as follows:
\[
\|y_{n+1}^* - p\| \leq \frac{1 + t_n (1 - \gamma_n)}{1 + t_n} \|y_n - p\| + \frac{t_n^2 (2 - \gamma_n)}{1 + t_n} \|y_n - Tv_n\|
+ \frac{t_n}{1 + t_n} \|Ty_{n+1}^* - Tv_n\| \leq (1 - t_n) \|y_n - p\| + t_n (\|Ty_{n+1}^* - Tv_n\| + 5t_n M_0).
\]
Using the inequality
\[
\frac{1 + t_n (1 - \gamma_n)}{1 + t_n} \leq 1 - t_n \gamma_n + (t_n)^2,
\]
we have
\[
\|y_{n+1} - p\| \leq \|y_{n+1}^* - p\| + \varepsilon_n
\leq (1 - t_n \gamma_n) \|y_n - p\| + t_n \|Ty_{n+1}^* - Tv_n\| + (\varepsilon_n + 3 \|u_n\|)
\leq (1 - t_n \gamma_n) \|y_n - p\| + (\varepsilon_n + 3 \|u_n\|)
\leq (1 - t_n \gamma_n) \|y_n - p\| + (\varepsilon_n + 3 \|u_n\|)
\]
(3.1)
\[
+ t_n (\|Ty_{n+1}^* - Tv_n\| + 5t_n M_0).
\]
Since
\[
\|y_{n+1}^* - v_n\| \leq t_n \|Tv_n - y_n\| + \|y_n - v_n\| + \|u_n\|,
\]
from our assumptions we have
\[
\|y_{n+1}^* - v_n\| \to 0 \quad (n \to \infty).
\]
The uniform continuity of \( T \) implies
\[
\|Ty_{n+1}^* - Tv_n\| \to 0 \quad (n \to \infty).
\]
Suppose \( \liminf_{n \to \infty} \gamma_n = \gamma > 0 \). For any \( \varepsilon \in (0, \frac{\gamma}{2}) \) and sufficiently large \( n \), \( \gamma - \varepsilon < \gamma_n \). Then the inequality (3.1) implies
\[
\|y_{n+1} - p\| \leq (1 - t_n (\gamma - \varepsilon)) \|y_n - p\| + (\varepsilon_n + 3 \|u_n\|)
+ t_n (\|Ty_{n+1}^* - Tv_n\| + 5t_n M_0).
\]
By Lemma 1 we obtain $\lim_{n \to \infty} ||y_n - p|| = 0$.

On the other hand, if $\liminf \gamma_n = \gamma = 0$, then $\liminf ||y_{n+1}^*-p|| = 0$. Setting $b_n = ||y_{n+1}^* - p||$, $f_1(t) = \phi(t)$, $f_2(t) = 1 + \phi(t) + t$, we can apply Lemma 3 to (3.1) and we have $\lim_{n \to \infty} ||y_n - p|| = 0$ (cf. [24]). This means that (I) hold.

(II) Let $w_n \to p$, then

$$||w_{n+1} - f(T, v_n, w_n)|| = ||w_{n+1} - t_n T v_n - (1 - t_n) w_n - u_n||$$

$$\leq ||w_{n+1} - p|| + t_n ||Tv_n - p|| + (1 - t_n) ||w_n - p|| + ||u_n||$$

$$\to 0 \quad (n \to \infty),$$

by the conditions of the theorem. From this (II) follows. \hfill \Box

Let $T_1, T_2, \ldots, T_k$ be $k$ selfmappings of an arbitrary Banach space $X$. We consider an iterative scheme $f(T_1, \ldots, T_k, \cdot) = f(\tau, \cdot)$ defined by (1.2) for a family of selfmappings $\tau = \{T_1, \ldots, T_k\}$ with $k$ coefficient sequences $\{t_n^{(j)}\}$ in $[0, 1]$ and $k$ error term sequences $\{u_n^{(j)}\}$ in $X$ for $j = 1, 2, \ldots, k$. Suppose that a sequence $\{x_n\}$ is defined by $x_{n+1} = f(\tau, x_n)$ for $x_1 \in X$. Letting $F(\tau)$ denote a set of common fixed points of $\tau$, we suppose that $x_n \to p \in F(\tau) \neq \emptyset$. Let $\{y_n\}$ be an arbitrary sequence in $X$. If

$$\lim_{n \to \infty} ||y_{n+1} - f(\tau, y_n)|| = 0 \text{ implies } y_n \to p,$$

then an iterative scheme $f(\tau, \cdot)$ is said to be $\tau$-stable or stable with respect to $\tau$. We say that an iterative scheme $f(\tau, \cdot)$ is almost $\tau$-stable or almost stable with respect to $\tau$ if

$$\sum_{n=1}^{\infty} ||y_{n+1} - f(\tau, y_n)|| < \infty \text{ implies } y_n \to p.$$

By applying Theorem 1 under assumption that $T_1$ is $\phi$-strongly pseudocontractive, we obtain Theorem 2 which proves strong convergence and almost stability of the iterative scheme $f(\tau, \cdot)$ defined by (1.2). This theorem generalizes Stević's result in [24]. Its proof is obtained from Theorem 1 by putting

$$v_n = t_n^{(2)} T_2 x_n^{(2)} + (1 - t_n^{(2)}) x_n + u_n^{(2)},$$

because Lemma 2 gives the boundedness of $\{x_n\}$ and we have $\lim_{n \to \infty} ||v_n - x_n|| = 0$.

**Theorem 2.** [26] Let $X$ be an arbitrary Banach space and let $T_1, \ldots, T_k$ be selfmappings of $X$ ($k \geq 2$). Let $f(\tau, \cdot)$ be the iterative scheme defined by (1.2) for $\tau = \{T_1, T_2, \ldots, T_k\}$. Suppose $T_1$ is a uniformly continuous $\phi$-strong pseudocontraction with a bounded range, and that $T_2$ has a bounded range. Suppose $F(\tau) \neq \emptyset$ and that the following conditions hold:

- (l) $\sum_{n=1}^{\infty} ||u_n^{(1)}|| < \infty$,
- (m) $\lim_{n \to \infty} ||u_n^{(2)}|| = 0$,
- (n) $\sum_{n=1}^{\infty} t_n^{(1)} = \infty$,
- (q) $\lim_{n \to \infty} t_n^{(j)} = 0$, for $j = 1, 2$. 

APPROSSIMAZIONE DI UN PUNTO FISSO

Allora le seguenti affermazioni sono vere.

(I) La sequenza \( \{x_n\} \) definita dalla (1.2) converge fortemente a \( p \in F(\tau) \).

(II) L'iterativo schema \( f(\tau, \cdot) \) è quasi \( \tau \)-stabile.

(III) Per qualsiasi sequenza \( \{y_n\} \) tale che \( y_n \rightarrow p \in F(\tau) \),

\[
\lim_{n \to \infty} \|y_{n+1} - f(\tau, y_n)\| = 0.
\]

4. Tassi di convergenza

Sia \( \Phi \) il sottoinsieme di tutte le funzioni \( f \) : \([0, \infty) \rightarrow [0, \infty) \) continue e, con \( f(0) = 0 \). Sia \( C \) un sottoinsieme chiuso e compatto di uno spazio normale arbitrario con diametro \( \delta(C) = M \), dove \( \delta(C) \) è il diametro di \( C \). Consideriamo \( \phi \in \Phi \) tale che la funzione \( \psi \) definita da

\[
\psi(t) = \begin{cases} \frac{\phi(t)}{t} & \text{se } t \in (0, M], \\ 0 & \text{se } t = 0 \end{cases}
\]

sia crescente e \( 0 \leq \psi(t) < 1 \) per tutti \( t \in [0, M] \). Tale \( \phi \) è detto essere una \( P \)-funzione su \( [0, M] \).

Per esempio,

\[
\phi(t) = \left( \frac{t}{M} \right)^2 \quad \text{e} \quad \phi(t) = \frac{t}{1 + \log M - \log t}
\]

sono \( P \)-funzioni su \([0, M]\). Siamo in grado di provare la seguente affermazione utilizzando il lemma di Kato (vedi [5]).

**Lemma 6.** [12] Sia \( C \) un sottoinsieme compatto di uno spazio normale arbitrario con diametro \( \delta(C) = M \), e sia \( T : C \rightarrow C \) una \( \phi \)-pseudocontrazione forte con \( \phi \in \Phi \). Allora per qualsiasi \( x, y \in C \) con \( x \neq y \), il seguente accostamento vale:

\[
\|x - y + t\{(I - T - \gamma_{xy} I)x - (I - T - \gamma_{xy} I)y\}\| \geq \|x - y\| \quad (t > 0),
\]

dove \( \gamma_{xy} = \frac{\phi(\|x - y\|)}{\|x - y\|} = \psi(\|x - y\|) \).

Utilizzando il lemma 6, otteniamo la seguente importante affermazione.

**Lemma 7.** [12] Sia \( C \) un sottoinsieme chiuso e compatto di uno spazio normale arbitrario con \( \delta(C) = M \), e sia \( \phi \) una \( P \)-funzione su \([0, M]\). Sia \( T : C \rightarrow C \) una \( \phi \)-pseudocontrazione forte e Lipschitz continua con un costante Lipschitz \( L \). Allora per Mann iteration \( \{x_n\} \) definita da (1.1), otteniamo la seguente stima: per un unico punto fisso \( p \in F(T) \),

\[
\|x_{n+1} - p\| \leq (1 - \gamma_n t_n + \tilde{L} t_n) \|x_n - p\| \quad (n \geq 0),
\]

dove \( \gamma_n = \psi(\|x_{n+1} - p\|) \) e \( \tilde{L} = 3 + 3L + L^2 \).

Sia \( N \) il sottoinsieme di tutti gli interi, e \( N_0 = N \cup \{0\} \). Per \( \beta \in (0, 1) \)

\[
C(\beta^K, \tilde{L}) = (1 - \frac{1}{\tilde{L}} \psi(M\beta^K)^2).
\]

È evidente che \( 0 < C(\beta^K, \tilde{L}) < 1 \).

Per \( t ) \) crescente, otteniamo anche che

\[
C(\beta^{K+1}, \tilde{L}) \leq C(\beta^K, \tilde{L}).
\]

Definiamo

\[
m_K = \min\{m \in \mathbb{N} : C(\beta^K, \tilde{L})^m \leq \beta \},
\]
and then define $n: N \to N$ by $n(0) = 0$ and $n(K) = n(K - 1) + m_K$, i.e.,

$$n(K) = n(0) + \sum_{j=1}^{K} m_j = \sum_{j=1}^{K} m_j.$$  

We have $0 = n(0) < n(1) < \cdots < n(K) < \cdots$. So, for each $n \in N_0$ we can find $K \in N_0$ with $n(K - 1) \leq n < n(K)$. Then, define $t_n \in (0, 1)$ by

$$t_n = \frac{1}{2L} \psi(M\beta^K).$$

Now, we can consider the Mann iteration $\{x_n\} \subset C$ with this coefficient sequence $\{t_n\}$ as follows:

$$\begin{cases}
  x_0 \in C, \\
  x_{n+1} = t_n T x_n + (1 - t_n) x_n.
\end{cases}$$

For such a sequence $\{n(K)\}_{K \in N_0}$ and the Mann iteration $\{x_n\} \subset C$, we obtain the following result.

**Theorem 3.** [12] Let $\beta \in (0, 1)$ be fixed. Then for the $\{n(K)\}_{K \geq 0}$ and $\{x_n\}$ defined above, we obtain the following estimate:

$$||x_n - p|| \leq M\beta^K, \quad (n \geq n(K)).$$

Next for a given $\beta$ and each $P$-function $\phi$, we give the convergence rate estimates for the Mann iteration involving $\phi$-strongly pseudocontraction $T$.

**Theorem 4.** [12] Under the assumption of the previous theorem, we obtain the following estimate of $n(K)$:

$$n(K) \leq K(1 + \log \beta) - 8\tilde{L}(\log \beta)\sum_{j=1}^{K} \frac{1}{\psi(M\beta^j)^2}, \quad (K \geq 1).$$

Moreover, for $\beta = \frac{1}{2}$, we have the following estimates: (1) if $\phi(t) = (\frac{t}{M})^2$, i.e., $\psi(t) = \frac{t}{M^2}$, then we have

$$n(K) \leq K(1 - \log 2) + \frac{32\tilde{L}}{3} (\log 2) M^2 4^K, \quad (K \geq 1).$$

(2) if $\phi(t) = \frac{t}{1 + \log M - \log t}$, i.e., $\psi(t) = \frac{1}{1 + \log M - \log t}$, then we have

$$n(K) \leq (1 + (8\tilde{L} - 1)(\log 2))K + 8\tilde{L}(\log 2)^2 K(K + 1) + \frac{4}{3}\tilde{L}(\log 2)^3 K(K + 1)(2K + 1), \quad (K \geq 1).$$

One can see that the Mann iteration which involves a $\phi$-strongly pseudocontraction $T$ with $\phi(t) = \frac{t}{1 + \log M - \log t}$ converges strongly to $p \in F(T)$ faster than one with $\phi(t) = (\frac{t}{M})^2$.
