Abstract

We study Julia components of transcendental entire functions with multiply-connected wandering domains. Under the assumption that the post singular set is contained in the Fatou set, it is shown that every repelling periodic point $p$ satisfies either

1. $C(p) \supset \partial U$, where $C(p)$ is the Julia component containing $p$ and $U$ is an immediate attractive basin.

2. $C(p) = \{p\}$ and this is a buried singleton component of $J(f)$.

§1 Introduction

Let $f$ be a transcendental entire function, $F(f)$ its Fatou set and $J(f)$ its Julia set. The following are some fundamental results on the connectivity of $J(f)$:

**Proposition 1** If every Fatou component is bounded and simply connected, then $J(f) \subset \mathbb{C}$ is connected.

So it follows that if $J(f) \subset \mathbb{C}$ is disconnected, then either

(a) $f$ has an unbounded Fatou component or

(b) $f$ has a multiply-connected Fatou component.

For the case (a), the following holds. Note that an unbounded Fatou component $U$ is always simply connected (see [Ba1]) and so we can consider a Riemann map $\varphi : \mathbb{D} \to U$ of $U$.

**Theorem 2** ([K, p.192, Main Theorem]) Suppose there exists an unbounded invariant Fatou component $U$ and let us consider the following conditions:
(A) $\infty \in \partial U$ is accessible in $U$.

(B) There exist a finite point $q \in \partial U$ with $q \notin P(f)$, $m_0 \in \mathbb{N}$ and a continuous curve $C(t) \subset U$ ($0 \leq t < 1$) with $C(1) = q$ which satisfies $f^{m_0}(C) \supset C$, where

$$P(f) = \bigcup_{n=0}^{\infty} f^n(\text{sing}(f^{-1}))$$

is the post-singular set of $f$.

(1) If $U$ is either an attractive basin with (A) and (B), or a parabolic basin with (A) and (B), or a Siegel disk with (A), then the set

$$\Theta_{\infty} := \{e^{i\theta} \mid \varphi(e^{i\theta}) := \lim_{r \nearrow 1} \varphi(re^{i\theta}) = \infty\} \subset \partial D$$

is dense in $\partial D$. In particular, $J(f) \subset \mathbb{C}$ is disconnected.

(2) If $U$ is a Baker domain with (B) and $f|U$ is not univalent, then $\Theta_{\infty}$ is dense in $\partial D$ or at least its closure $\overline{\Theta_{\infty}}$ contains a certain perfect set in $\partial D$. In particular, $J(f) \subset \mathbb{C}$ is disconnected.

Next result is a generalization of the above result:

**Theorem 3** [BD1, p.439, Theorem 1.1, 1.2, Corollary 1.3] Theorem 2 holds without the assumption (B).

On the other hand, $J(f) \subset \mathbb{C}$ can be connected nevertheless $f$ has an unbounded Fatou component. For example,

$$f(z) = 2 - \log 2 + 2z - e^z$$

has a Baker domain but $J(f)$ is connected ([K, p.194, Theorem 4]).

For the case (b), it is known that if $f$ has a multiply-connected Fatou component $U$, then $U$ is a wandering domain and bounded (see, [Ba2, Theorem 3.1]) and therefore $J(f) \subset \mathbb{C}$ is always disconnected. Furthermore $J(f) \cup \{\infty\} \subset \hat{\mathbb{C}}$ is also disconnected and actually this is the only case where $J(f) \cup \{\infty\} \subset \hat{\mathbb{C}}$ can be disconnected as follows:

**Proposition 4** ([K, p.191, Theorem 1]) $J(f) \cup \{\infty\} \subset \hat{\mathbb{C}}$ is disconnected if and only if $f$ has a multiply-connected wandering domain.

In what follows, we will concentrate on the case (b), that is, the case where $f$ has a multiply-connected wandering domain $U$ and investigate some properties of connected components of the Julia set, which we call *Julia components*. We note the following fact (see, [Ba2, p.565, Theorem 3.1]):

**Proposition 5** If $U$ is a multiply-connected wandering domain, then $f^n|U \to \infty$. 
Definition 6  (1) We call a connected component of $J(f)$ a **Julia component**.

(2) $z \in J(f)$ is called a **buried point** if $z$ satisfies $z \notin \partial U$ for any Fatou component $U$.

(3) We call the set

$$J_0(f) := \{z \in J(f) \mid z \text{ is a buried point}\}$$

the **residual Julia set** of $f$.

(4) A Julia component $C$ is called a **buried component** if $C \subset J_0(f)$.

For rational cases, the following are known:

**Example 7 ([Mc])** Let $f(z) = z^2 + \frac{\lambda}{z^3}$, where $\lambda > 0$ is small. Then $J(f)$ is a Cantor set of nested quasi-circles. So there are buried components. In particular, $J_0(f) \neq \emptyset$.

**Theorem 8 ([Mo, p.208, Theorem 3])** Let $f$ be a hyperbolic rational function. Then $J_0(f) \neq \emptyset$ if and only if

1. $F(f)$ has a completely invariant component, or
2. $F(f)$ consists of only two components.

**Example 9 ([Mo, p.209])** Let $f(z) = \frac{-2z + 1}{(z - 1)^2}$, then the following hold:

1. The set $\{0, 1, \infty\}$ is a super-attracting cycle.
2. $f$ is hyperbolic.
3. Any Fatou component is a preimage of the super-attractive basin above.
4. $J(f)$ is connected.

So by Theorem 8, we have $J_0(f) \neq \emptyset$. But since $J(f)$ is connected, there is no buried component.

**Example 10 ([U])** There exists a rational function $f$ whose Julia set is homeomorphic to a Sierpinski gasket. So $J_0(f) \neq \emptyset$, but again there is no buried component.

Here are some fundamental properties for buried points and residual Julia sets. Note that $f$ need not be rational and these hold also for transcendental entire functions and even for meromorphic functions.

**Proposition 11**  (1) If $F(f)$ has a completely invariant component, then $J_0(f) = \emptyset$.

(2) If there exists a buried component of $J(f)$, then $J(f)$ is disconnected.

(3) If $J_0(f) \neq \emptyset$, then $J_0(f)$ is completely invariant, dense in $J(f)$, and uncountable.

More information on residual Julia sets, see [DF].
§2 Results

Main result of this paper is as follows:

**Theorem A**  Let $f$ be a transcendental entire function. Assume that

(a) $P(f) = \bigcup_{n=0}^{\infty} f^n(\text{sing}(f^{-1})) \subset F(f)$,

(b) $f$ has a multiply-connected wandering domain.

Then every repelling periodic point $p$ satisfies either one of the following:

1. $C(p) \supset \partial U$, where $C(p)$ is the Julia component containing $p$ and $U$ is an immediate attractive basin.
2. $\{p\}$ is a buried singleton component of $J(f)$.

**Corollary B**  Let $f$ be a transcendental entire function. Assume the above conditions (a), (b) and also

(c) $f^n(z) \to \infty$ for any $z \in F(f)$.

Then every repelling periodic point $p$ is a buried singleton component of $J(f)$.

**Remark**  $f$ is called hyperbolic if

$$\text{dist}_{\mathbb{C}}(P(f), J(f)) > 0,$$

where $\text{dist}_{\mathbb{C}}$ is the Euclidean distance on $\mathbb{C}$. So the condition (a) in Theorem A is slightly weaker than hyperbolicity.

**Outline of the Proof:**  Let $p$ be a repelling periodic point. For simplicity, we assume that $p$ is a fixed point. Suppose that $p$ does not satisfy (1). Let $C(p) \subset J(f)$ be the Julia component containing $p$. Then $f(C(p)) = C(p)$ and we can show that $C(p)$ is bounded. If there exists a Fatou component $U \subset F(f)$ such that $C(p) \cap \partial U \neq \emptyset$, then it follows that $U$ is a wandering domain which satisfies $f^n(U) \to \infty$ ($n \to \infty$). Then this contradicts the fact that $C(p)$ is bounded. Hence $C(p)$ is a buried component.

Next we can show that the complement of $C(p)$ has no bounded component. Then since $P(f) \subset F(f)$ and $C(p)$ is bounded, we have

$$\text{dist}_{\mathbb{C}}(C(p), P(f)) > 0.$$

Then there exists a simply connected domain $W$ such that $C(p) \subset W$ and there exists a branch $g_n$ of $f^{-n}$ which satisfies $g_n(p) = p$. It is well-known that $\{g_n\}_{n=1}^{\infty}$ is a normal family and hence there exists a subsequence $g_{n_1}$ converging to a constant function which must be the point $p$. On the other hand, we have $g_n(C(p)) = C(p)$, so we conclude that $C(p) = \{p\}$. This completes the proof of Theorem A. Corollary B is an immediate consequence of Theorem A.
§3 Examples

Example 12 ([BD2, p.375, Theorem G]) There exists an $f(z)$ with the following form

$$f(z) = k \prod_{n=1}^{\infty} \left(1 + \frac{z}{r_n}\right), \quad 0 < r_1 < r_2 < \cdots, \quad k > 0$$

such that for every repelling periodic point $p$ is a buried singleton component of $J(f)$.

Example 13 ([KS]) There exists a transcendental entire function $f$ with doubly-connected wandering domains, which satisfies the following: Every critical point $c$ satisfies $f^2(c) = 0$ and 0 is a super-attracting fixed point. This implies that this $f$ satisfies the assumptions of Theorem A. Therefore every repelling periodic point $p$ satisfies either $C(p) \supset \partial U$ for the immediate attractive basin $U$ of the super-attractive fixed point 0 or $\{p\}$ is a buried singleton component of $J(f)$.

Example 14 ([Be]) By using the similar method as in Example 13, Bergweiler constructed an example of transcendental entire function $f$ which has both a simply connected and a multiply connected wandering domain. Critical points of $f$ satisfy the following:

1. $c_0 = 0 < c_1 < c_2 < \cdots \to \infty$,
2. $f(0) = 0, \quad f(c_i) = c_{i+1}, \quad i = 1, 2, \ldots$
3. $c_i$ is contained in a simply connected wandering domain $U_i$ which satisfies

$$f(U_i) = U_{i+1}, \quad f^n|U_i \to \infty \quad (n \to \infty).$$

So this $f$ also satisfies the assumptions (a) and (b) of Theorem A.

Example C We can construct an $f$ which satisfies the assumptions (a), (b) and (c) by using the similar method as in Example 13. Hence every repelling periodic point $p$ is a buried singleton component of $J(f)$ from Corollary B. We omit the details.
