Kyoto University
Non-tempered automorphic representations of inner forms of $Sp(4)$

九州大学 GCOE 研究員 安田 貴徳 (Takanori Yasuda)
Faculty of Mathematics,
Kyushu University

1 INTRODUCTION

For a reductive group $G$ defined over a number field $k$, an unitary representations of $G(A_k)$ on the space of $L^2$-automorphic forms $L^2(G(k)\backslash G(A_k))$ is defined by the right regular action. As for the irreducible decomposition of its discrete spectrum $L^2_{\text{disc}}(G(k)\backslash G(A_k))$, Arthur gave a conjecture [2]. It says that $L^2_{\text{disc}}(G(k)\backslash G(A_k))$ should decompose into $G(A_k)$-invariant subspaces parametrized by elliptic $A$-parameters. For an elliptic $A$-parameter $\psi$, the set $\Pi_{\psi}$ of irreducible automorphic representations of $G(A_k)$ appearing the associated subspaces is called $A$-packet for $\psi$. For any place $v$ of $k$, a finite set $\Pi_{\psi_v}$ of irreducible admissible representations of $G(k_v)$, which is called a local $A$-packet, should exist so that $\Pi_{\psi}$ is a subset of

$$\{ \bigotimes_v' \pi_v \mid \pi_v \in \Pi_{\psi_v} \text{ and } \pi_v \text{ is unramified for almost all } v \}.$$  

Arthur also conjectured the multiplicity of $\pi \in \Pi_{\psi}$ in the associated subspace for $\psi$. To describe the multiplicity, we need the information about global and local $S$-group for $\psi$, and pairings between $S$-groups and $A$-packets.

In this note, we treat the case that $G$ is a non-split inner form of $Sp(4)$. ($Sp(4)$ is the isometry group of 4-dimensional symplectic space.) I give an evaluation of the multiplicities of non-tempered irreducible automorphic representations which appear in the residual spectrum, or are CAP representations (Theorem 4.1, Theorem 5.1 and Proposition 6.2). Here a cuspidal representation $\pi$ is said to be of CAP if for any cusp form $\phi$ in $\pi$ which is $K$-finite where $K$ is a maximal compact subgroup of $G(A_k)$, there exists an element $\phi'$ of an irreducible component of the residual spectrum such that $\phi$ and $\phi'$ share the same absolute values of Hecke eigenvalues at almost all places of $k$. According to Arthur’s conjecture, any irreducible non-tempered automorphic representation of $G(A_k)$ appears in $A$-packet for some $A$-parameter $\psi$ of DAP type. Here an $A$-parameter $\psi : \mathcal{L}_k \times SL(2, \mathbb{C}) \to LG$ where $\mathcal{L}_k$ is the hypothetical Langlands group of $k$ and $^LG$ is the $L$-group of $G$ is said to be of DAP type if $\psi$ is elliptic and the restriction to $SL(2, \mathbb{C})$ of $\psi$ is non-trivial. This implies that irreducible non-tempered automorphic representations should be exhausted by the irreducible components of the residual spectrum and CAP representations.

From the evaluation of the multiplicity for irreducible non-tempered automorphic representation of $G(A_k)$, we can guess a explicit description of multiplicity of these representations (Expectation 8.1). Our interest is whether this description coincides with the Arthur’s conjectural multiplicity. More precisely, the problem is whether there are pairings between $S$-groups and $A$-packets such that the description coincides with the Arthur’s multiplicity defined by these pairings. Our main result is that such pairings exist (Section
8). Remark that the local pairings defined in this result satisfy the conjecture of Hiraga and Saito.

2 INNER FORMS OF $Sp(2)$

Let $k$ be a number field and $A$ its adele ring. $| |_A$ denotes the idele norm of $A^\times$. For any place $v$ of $k$, we write $k_v$ for the completion of $k$ at $v$ and $| |_v$ for the $v$-adic norm. Let $\mu$ be a non-trivial character of $A$ which is trivial on $k$.

Let $D$ be a quaternion division algebra over $k$. We write $\nu, \tau$ and $\iota$ for the reduced norm, the reduced trace and the main involution of $D$, respectively. We write $S_D$ for the set of places $v$ of $k$ at which $D$ is ramified, which has finite and even elements. Let $W = D^{\otimes 2}$ be the free left module over $D$ with rank two, and we equip it with a hermitian form $\langle, \rangle$ given by

$$\langle(x_1, y_1), (x_2, y_2)\rangle = x_1 y_2 + y_1 x_2 \quad (x_1, x_2, y_1, y_2 \in D).$$

Let $G$ be the unitary group of this form, so that

$$G = \left\{ g \in GL(2, D) \mid g \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \right\}.$$

Here we write $^*(a_{i,j}) = (a_{j,i})$ for $(a_{i,j}) \in M(2, D)$. It can be regarded as a reductive group defined over $k$. It is non-quasisplit and an inner form of $Sp(2)$ with respect to a quadratic extension $k'$ of $k$ such that all $v \in S_D$ do not split fully in $k'/k$. Fix a $k$-parabolic subgroup $P$ and its Levi factor $M$ as

$$P = \left\{ \begin{pmatrix} * & * \\ * & * \end{pmatrix} \in G \right\}, \quad M = \left\{ \begin{pmatrix} x & 0 \\ 0 & (\iota x)^{-1} \end{pmatrix} \mid x \in D^\times \right\},$$

$P$ is the unique proper parabolic subgroup of $G$ up to $G(k)$-conjugate and corresponds to the Siegel parabolic subgroup via an inner twist. We write again $\nu$ for the character of $M$ corresponding to the reduced norm. $U$ denotes the unipotent radical of $P$, so that

$$U = \left\{ \begin{pmatrix} 1 & y \\ 0 & 1 \end{pmatrix} \mid \tau(y) = 0 \right\}.$$

$G(k) \backslash G(A)$ becomes a locally compact Hausdorff space and has a non-zero $G(A)$-invariant measure up to scalars. Fix such a measure $dg$. Then the space $L^2(G(k) \backslash G(A))$ of square-integrable functions on $G(k) \backslash G(A)$ is defined and the representation $\rho$ of $G(A)$ on $L^2(G(k) \backslash G(A))$ is defined by

$$\rho(g)f(x) = f(xg) \quad (x, g \in G(A)).$$

This representation has an orthogonal decomposition;

$$L^2(G(k) \backslash G(A)) = L^2_{disc}(G) \oplus L^2_{cont}(G),$$

where $L^2_{disc}(G)$ is the maximal completely reducible closed subspace of $L^2(G(k) \backslash G(A))$ and $L^2_{cont}(G)$ is its orthogonal complement. For $\phi \in L^2(G(k) \backslash G(A))$ its constant term $\phi_P$ along $P = MU$ is defined by

$$\phi_P(g) = \int_{U(k) \backslash U(A)} \phi(ug)du \quad (g \in G(A)).$$
where $du$ is a Haar measure of $U(k) \backslash U(A)$. $L^2_0(G)$ denotes the space of cuspidal elements of $L^2(G(k) \backslash G(A))$, that is, elements whose constant terms along $P$ vanish. It is known that $L^2_0(G)$ is a $G(A)$-invariant closed subspace contained in $L^2_{disc}(G)$ [7]. We write $L^2_{res}(G)$ for its orthogonal complement in $L^2_{disc}(G)$, which is called the residual spectrum. In this note, we call an irreducible component of $L^2_{disc}(G)$ an irreducible automorphic representation of $G(A)$. Any irreducible automorphic representation $\pi$ of $G(A)$ has a decomposition into a restricted tensor product $\pi \simeq \bigotimes_v \pi_v$. From the Langlands' spectral theory of Eisenstein series, the residual spectrum of $G$ coincides with the space of residues of Eisenstein series associated to the cuspidal representations of $M(A)$.

3 Decomposition of Discrete Spectrum

Assume the existence of the hypothetical Langlands group $L_k$ of $k$. The $L$-group $L^G$ of $G$ is $\hat{G} \times W_k = SO(5, \mathbb{C}) \times W_k$ where $W_k$ is the Weil group of $k$. By an $A$-parameter is meant a continuous homomorphism $\phi : L_k \times SL(2, \mathbb{C}) \rightarrow L^G$ such that

(i) writing $p_k : L_k \rightarrow W_k$ for the conjectural homomorphism and $p_2 : L^G \rightarrow W_k$ the projection to the second component, $p_2 \circ \phi = p_k$.

(ii) its restriction to $L_k$ is a Langlands parameter with bounded image [4], and

(iii) its restriction to $SL(2, \mathbb{C})$ is analytic.

Two $A$-parameters are equivalent if they are $\hat{G}$-conjugate. The set of equivalence classes of $A$-parameters is denoted by $\Psi(G)$. We write $C_\psi$ for the centralizer of the image of $\psi$ in $\hat{G}$. An $A$-parameter $\psi$ is said to be elliptic if $C_\psi$ is contained in the center $Z(\hat{G})$ of $\hat{G}$. The subset of elliptic elements of $\Psi(G)$ is denoted by $\Psi_0(G)$. An $A$-parameter $\psi$ is of $DAP$ type ($DAP$ is the abbreviation of "Discrete Associated to Parabolic") if

(i) $\psi$ is elliptic, and

(ii) $\psi|_{SL(2, \mathbb{C})}$ is not trivial.

$Ψ_{DAP}(G)$ denotes the subset of $Ψ_0(G)$ consisting of the elements of DAP type. From the property (iii) of the definition of $A$-parameter, elements of $Ψ(G)$ is classified by the irreducible decomposition of their restriction to $SL(2, \mathbb{C})$. As for homomorphisms $SL(2, \mathbb{C}) \rightarrow \hat{G}$ we have the following result.

Proposition 3.1 ([5]). 1. (Jacobson-Morozov)

\{homomorphism $SL(2, \mathbb{C}) \rightarrow SO(5, \mathbb{C})\} / \sim \approx \{\text{nilpotent orbits in } so(5, \mathbb{C})\} / \sim,

2. $\{\text{nilpotent orbits in } so(5, \mathbb{C})\} / \sim \approx \{\text{partition of } [n_1^{k_1}, \ldots, n_l^{k_l}] \text{ of } 5 \mid n_i: even \Rightarrow k_i: even\}$

$= \{[1^5], [2^2, 1], [3, 1^2], [5]\}$.

Here $\sim$ means $SO(5, \mathbb{C})$-conjugacy.

By this proposition we have a decomposition

$$Ψ_0(G) = Ψ_0(G)_{[1^5]} \sqcup Ψ_0(G)_{[2^2, 1]} \sqcup Ψ_0(G)_{[3, 1^2]} \sqcup Ψ_0(G)_{[5]}.$$ (3.1)
In addition, we have
\[ \Psi_{DAP}(G) = \Psi_0(G)_{[2^2,1]} \sqcup \Psi_0(G)_{[3,1^2]} \sqcup \Psi_0(G)_{[5^3]} \]

Arthur’s conjecture [2] implies a coarse decomposition
\[ L^2_{\text{disc}}(G(k)\backslash G(A)) = \bigoplus_{\psi \in \Psi_0(G)} L^2(G)_{\psi} \]  \hspace{1cm} (3.2)

The set of irreducible automorphic representations appearing in \( L^2(G)_{\psi} \) is denoted by \( \Pi_{\psi}^{G} \).

By (3.1) and (3.2) we have the decomposition,
\[ L^2_{\text{disc}}(G(k)\backslash G(A)) = L^2_{[1^5]}(G) \oplus L^2_{[2^2,1]}(G) \oplus L^2_{[3,1^2]}(G) \oplus L^2_{[5]}(G) \]

Arthur’s conjecture also implies the space spanned by non-tempered cuspidal representations of \( G(A) \) coincides with \( \bigoplus_{\psi \in \Psi_{DAP}(G)} L^2(G)_{\psi} \).

We will consider the multiplicity for irreducible non-tempered automorphic representation. Since \( \Psi_0(G)_{[5]} \) consists of one element \( \psi_0 = 1 \otimes \text{Sym}^4 \) where \( \text{Sym}^4 \) is the 4-th symmetric power of \( SL(2, \mathbb{C}) \), and \( L^2_{[5]}(G) = L^2(G)_{\psi_0} \) should be \( \mathbb{C} \cdot 1 \), we will treat mainly the case of \( L^2_{[2^2,1]}(G) \) and \( L^2_{[3,1^2]}(G) \). We will say that \( \psi \in \Psi_0(G)_{[2^2,1]} \) and irreducible components of \( L^2_{[2^2,1]}(G) \) are of Saito-Kurokawa type, and \( \psi \in \Psi_0(G)_{[3,1^2]} \) and irreducible components of \( L^2_{[3,1^2]}(G) \) are of Soudry type.

4 Residual spectrum of \( G \)

**Theorem 4.1** ([10]). Let \( k \) be a totally real number field. The irreducible components of the residual spectrum of \( G \) consist of the following representations.

1. The trivial representation \( 1_{G} \),
2. The unique irreducible quotient \( J^G_{\sigma}(\sigma) \) of \( \text{Ind}^{G(A)}_{\mathcal{P}(A)}(\sigma|\nu_{A}^{1/2}) \). Here \( \sigma \) runs over the set of infinite dimensional irreducible self-dual cuspidal representations of \( M(A) \) whose standard \( L \)-functions \( L(\sigma, s) \) do not vanish at \( s = 1/2 \), and
3. The theta lift \( R(V) \) from the trivial representation of \( G(V_{\mathbb{A}}) \) under the Weil representation \( \omega_{V_{\mathbb{A}}} \). Here \( V \) runs over the set of local isometry classes of \(-1\)-hermitian right \( D \)-spaces of dimension one, and \( G(V) \) is the unitary group of \( V \).

In the case (1) and (2), the multiplicity of each representation is one. In the case (3), the multiplicity of each representation is \( 2^{|S_{D}| - 2} \).

**Remark 4.2.** In case of general \( k \), it can be shown that the residual spectrum is exhausted by these automorphic representations and the multiplicity of representation in the case (3) is greater than or equal to \( 2^{|S_{D}| - 2} \).
All irreducible representations appearing in the residual spectrum are non-tempered by the Langlands classification. Therefore these representations belong to some $A$-packets of DAP type. From the description of local components of these automorphic representations these associated $A$-parameters should be the following.

(1) $1_G$ correspond to
$$\phi = \psi_0 = 1_S \otimes \text{Sym}^4 \times p_k.$$

(2) $J^G_2(\sigma)$ correspond to
$$\phi = ((\phi_\sigma \otimes \text{St}) \oplus (1_{L_k} \otimes 1_{SL(2,\mathbb{C})})) \times p_k.$$

Here St is the standard representation of $SL(2, \mathbb{C})$ and $\phi_\sigma$ is the Langlands parameter associated to $\sigma$, whose image is contained by $SL(2, \mathbb{C})$.

(3) $R(V)$ correspond to
$$\phi = \left( (\text{Ind}_{W_{k'}}^{W_k} 1_{W_k} \otimes 1_{SL(2,\mathbb{C})}) \oplus (\omega_{k'/k} \otimes \text{Sym}^2) \right) \circ p_k \times p_k.$$

Here $\omega_{k'/k}$ is the quadratic character of $W_k$ associated to $k'/k$. Remark the image of $\text{Ind}_{W_{k'}}^{W_k} 1_{W_k}$ is contained by $O(2, \mathbb{C})$.

As we have already explained $1_G$ spans $L_2[5](G)$. The $A$-parameters of (2) are of Saito-Kurokawa type and those of (3) are of Soudry type.

5 CAP REPRESENTATIONS OF SAITO-KUROKAWA TYPE

Let $B$ be a quaternion algebra over $k$. $\iota_B$ denotes the main involution of $B$ and $S_B$ is defined similarly for $S_D$. Take $\eta \in D$ such that $\iota \eta = -\eta$ and $\eta^2 = p \in k^\times$. We write $K = k(\eta)$, which is a quadratic extension of $k$. Suppose that $K$ can be embedded in $B$. A $K/k$-skew-hermitian form on $B$ is defined by
$$h(x, y) := \eta \cdot (\iota_B x \cdot y)_K \quad (x, y \in B),$$

where $(\_)_K$ is the projection to $K$-part of $B$. A $(D, \iota)$-skew-hermitian right space $(V_B, \eta, h_B, \eta)$ of rank 2 is defined as
$$(V_B, h_B, \eta) = (B \otimes K D, h \otimes 1).$$

$G(V_B, \eta)$ denotes the unitary group of $(V_B, \eta, h_B, \eta)$. This is an inner form of $O(4)$. We write $G_0(V_B, \eta)$ for the $k$-group of elements of $G(V_B, \eta)$ whose reduced norm is one. Writing $\overline{B}$ for the quaternion algebra over $k$ such that $B \cdot \overline{B} = D$ in the Brauer group of $k$,
$$G_0(V_B, \eta) \simeq \left\{ (b, \overline{b}) \in B^\times \times \overline{B}^\times \mid \nu_B(b) = \nu_{\overline{B}}(\overline{b})^{-1} \right\} / \{(z, z^{-1}) \mid z \in G_m\}. \quad (5.1)$$

Therefore any irreducible cuspidal representation of $G_0(V_B, \eta, \lambda)$ is written in the form $\sigma_B \otimes \sigma_{\overline{B}}$ where $\sigma_B$ and $\sigma_{\overline{B}}$ are irreducible cuspidal representations of $B^\times_\lambda$ and $\overline{B}^\times_\lambda$, respectively. Since $(G(V_B, \eta), G)$ is a dual reductive pair we can consider the Weil representation $\omega_{V_B, \eta, \mu}$ of $G(V_B, \eta) \times G(\mathbb{A})$. Let $(\sigma, V_\sigma)(\simeq \bigotimes_v \sigma_v)$ be an irreducible cuspidal representation of
$B^\times$ with trivial central character. Any element of $V_\sigma$ can be regarded as an automorphic form on $G_0(V_{B,\eta},A)$ by (5.1). For $\phi \in V_\sigma$ and $f \in S(V_{B\eta,\eta})$, define

$$
\theta(f, \phi)(g) = \int_{h \in G_0(V_{B,\eta},k) \backslash G_0(V_{B,\eta},A)} \theta(f, h, g) \phi(h) \text{d}h \quad (g \in G(A))
$$

$$
\theta(f, h, g) = \sum_{x \in V_{B,\eta}} \omega_{V_{B,\eta},\psi}(h, g) f(x) \quad (h \in G(V_{B,\eta}, A)).
$$

Put $\Theta(\sigma, B, \eta) = \{\theta(f, \phi) \mid f \in S(V_{B\eta,\eta}), \phi \in V_\sigma\}$. This is $G(A_f) \times (g_\infty, K_\infty)$-module by the right regular action. Here $A_f, A_\infty$ are the finite and infinite parts of $A$, and $g_\infty$ is the complexification of the Lie algebra of $G(A_\infty)$, and $K_\infty$ is a maximal compact subgroup of $G(A_\infty)$.

**Theorem 5.1.** 1. Let $\sigma$ be infinite dimensional and

(a) $L(\sigma, 1/2) \neq 0$, where $L(\sigma, s)$ is the Jacquet-Langlands $L$-function,

(b) $\epsilon(\sigma_v \otimes \omega_{K_v/k_v}, 1/2) = \delta_v \omega_{K_v/k_v}(-1)\epsilon(\sigma_v, 1/2)$ for all places $v$. Here $\omega_{K_v/k_v}$ is the quadratic character associated to $K_v/k_v$ and $\epsilon(\sigma_v, 1/2)$ is the Jacquet-Langlands $\epsilon$-factor which is independent of a choice of non-trivial character of $k_v$, and

$$
\delta_v = \begin{cases} 
1 & \text{if } v \notin S_B \\
-1 & \text{if } v \in S_B.
\end{cases}
$$

Then $\Theta(\sigma, B, \eta)$ is non-zero, irreducible, non-tempered and cuspidal if $B$ is not isomorphic to $D$.

2. For the local decomposition $\Theta(\sigma, B, \eta) \simeq \bigotimes_v \Theta(\sigma, B, \eta)_v$, $\Theta(\sigma, B, \eta)_v$ can be determined as a representation for any $v$. (This description of local factors will be seen as elements of local $A$-packets later.)

This theorem is proved by using the condition of non-vanishing of Shimura correspondence in [9]. From the description of all $\Theta(\sigma, B, \eta)_v$ the $A$-parameter of $\Theta(\sigma, B, \eta)$ should be

$$
\psi_\sigma = (\phi_\sigma \otimes \text{St}) \oplus (1_{L_k} \otimes 1_{SL(2,\mathbb{C})}) \times p_k
$$

where $\phi_\sigma$ is the Langlands parameter of $\sigma$. This $A$-parameter is of Saito-Kurokawa type.

6 CAP REPRESENTATIONS OF SOUDRY TYPE

Let $V = V_\xi$ be the one-dimensional skew-hermitian space over $(D, \iota)$ defined by $\xi \in D$ with $\tau(\xi) = 0$. Let $\delta = \det V_\xi = \nu(\xi) = -\xi^2 \mod (k^\times)^2$ and $k' = k(\xi) \simeq k(\sqrt{-\delta})$. $G(V)$ and $G_0(V)$ denote the unitary group and special unitary group of $V$, respectively. Then $G_0(V)$ is isomorphic to the norm torus for the quadratic extension $k'/k$. Since $(G(V), G)$ is a dual reductive pair we can consider the Weil representation $\omega_{V, \mu}$ of $G(V_k) \times G(A)$. Let $\chi = \prod_v \chi_v$ be a non-trivial character of $G_0(V_k) \backslash G_0(V_k)$ and put $S_\chi = \{v \mid \chi_v^2 = 1\}$. Since

$$
\text{Ind}_{G_0(V_k)}^{G(V_k)} \chi \subset L^2_{\text{disc}}(G(V)) = L^2(G(V))
$$
we want to construct an irreducible automorphic representation of $G(\mathbb{A})$ by the theta lift from $\text{Ind}_{G_0(V_\mathbb{A})}^{G(V_\mathbb{A})} \chi$. However $\text{Ind}_{G_0(V_\mathbb{A})}^{G(V_\mathbb{A})} \chi$ is not irreducible. Therefore the description of its irreducible decomposition is needed. As for its local component we have

$$\text{Ind}_{G_0(V_v)}^{G(V_v)} \chi_v \simeq \begin{cases} \tilde{\chi}_v^+ \oplus \tilde{\chi}_\bar{v} & v \in S_\chi \cap S_{D^c}, \\ \tilde{\chi}_v & \text{otherwise.} \end{cases}$$

Here $\tilde{\chi}_v^+$, $\tilde{\chi}_\bar{v}$ are characters not isomorphic to each other, and $\tilde{\chi}_v$ is $\chi_v$ if $v \in S_D$ and a two-dimensional irreducible representation otherwise. Fix a $\gamma_0 \in O(k', N_{k'/k}) \backslash SO(k', N_{k'/k})$ and embed $\gamma_0$ in $G(V_v) \simeq O(k'_v, N_{k'_v/k_v})$ for all $v \not\in S_D$. For $v \in S_\chi \cap S_{D^c}$ we may assume $\tilde{\chi}_v^+(\gamma_0) = 1$, which characterizes $\tilde{\chi}_v^+$ and $\tilde{\chi}_\bar{v}$. Then an irreducible component of the above induced representation is of form,

$$\tau = (\bigotimes_{v \in S} \tilde{\chi}_v^-) \otimes (\bigotimes_{v \in S_\chi \setminus S} \tilde{\chi}_v^+) \otimes (\bigotimes_{v \not\in S_\chi} \tilde{\chi}_v)$$

for some finite set $S \subseteq S_\chi \cap S_{D^c}$. In this case write $\tau = \tau_S$. For any $v \in S_\chi \cap S_{D^c}$ define

$$S^{\pm}(V_v) = \{ f \in S(V_v) | f(\gamma_0 \cdot) = \pm f \}$$

where $S(V_v)$ is the space of Schwartz-Bruhat functions on $V_v$. For $f \in S(V_\mathbb{A})$, define

$$\theta(f, h, g) = \sum_{x \in V_k} \omega_{V_\psi}(h, g) f(x) \quad (g \in G(\mathbb{A}), h \in G(V_\mathbb{A}))$$

The theta lift from $\tau_S$ is defined as follows.

(I) $\chi^2 \neq 1$

The theta integral is defined by

$$\theta(f, \chi)(g) = \int_{G_0(V_k) \backslash \text{G}_0(V_\mathbb{A})} \theta(f, h, g) \chi(h) dh.$$ 

The theta lift $\Theta(V_\mathbb{A}, \chi, S)$ from $\tau_S$ is defined by $\Theta(V_\mathbb{A}, \chi, S) = \{ \theta(f, \chi) | f \in S_S(V_\mathbb{A}) \}$ where $S_S(V_\mathbb{A}) = (\bigotimes_{v \in S} S^-(V_v)) \otimes (\bigotimes_{v \in S_\chi \setminus S} S^+(V_v)) \otimes (\bigotimes_{v \not\in S_\chi} S(V_v))$.

(II) $\chi^2 = 1$

In this case $\tau_S$ is one-dimensional. The theta integral is defined by

$$\theta(f, \chi)(g) = \int_{G(V_\mathbb{A}) \backslash G(\mathbb{A})} \theta(f, h, g) \tau_S(h) dh,$$

The theta lift $\Theta(V_\mathbb{A}, \chi, S)$ from $\tau_S$ is defined by $\Theta(V_\mathbb{A}, \chi, S) = \{ \theta(f, \chi) | f \in S(V_\mathbb{A}) \}$.

In any case, $\Theta(V_\mathbb{A}, \chi, S)$ becomes a $G(\mathbb{A}_f) \times (\mathfrak{g}_\infty, K_\infty)$-module by right regular action.

**Theorem 6.1.**

1. $\Theta(V_\mathbb{A}, \chi, S)$ is non-zero, irreducible, non-tempered and cuspidal.

2. For the local decomposition $\Theta(V_\mathbb{A}, \chi, S) \simeq \bigotimes_v \Theta(V_v, \chi, S)_v$, $\Theta(V_v, \chi, S)_v$ can be determined as a representation for any $v$. (This description of local factors will be seen as elements of local A-packets later.)
\( \Theta(V, \chi, S) \) is an inner form analogue of the following representation of \( Sp(4, A) \).

\[
\Theta(V, \chi, S) = \text{quot. of } \text{Ind}^{Sp(4,A)}_{P_{K}(A)}(\theta(k', \chi) \otimes \omega_{k'/k} | \cdot |_{A}) \colon Sp(4)
\]

Here \( O(k') \) is the orthogonal group of the 2-dimensional quadratic space \( (k', N_{k'/k}) \) where \( k' \) is a quadratic extension of \( k \), and \( P_{K} \) is the Klingen parabolic subgroup of \( Sp(4) \). This fact is used to prove the above theorem. As for the multiplicity \( m(\Theta(V, \chi, S)) \) of \( \Theta(V, \chi, S) \) in \( L^{2}_{\text{disc}}(G) \) we have the following evaluation.

**Proposition 6.2.**

\[
m(\Theta(V, \chi, S)) \geq \begin{cases} 
2^{|S_{\chi} \cap S_{D}| - 1} & \text{if } \chi^{2} \neq 1, S_{D} \cap S_{\chi} \neq \emptyset, \\
2^{|S_{D}| - 2} & \text{if } \chi^{2} = 1, S_{D} \cap S_{\chi} \neq \emptyset, \\
1 & \text{if } S_{D} \cap S_{\chi} = \emptyset.
\end{cases}
\]

This result is caused by the failure of Hasse's principle for skew-hermitian spaces. This proposition is shown by using the difference of Fourier coefficients arising from the failure of Hasse's principle.

The \( A \)-parameter of \( \Theta(V, \chi, S) \) must be same to that of the representation of \( Sp(4, A) \) constructed above. By Adams conjecture [1], this \( A \)-parameter should be given by \( \psi_{k', \chi} \) in the following diagram.

\[
\psi_{k', \chi} = (\text{Ind}_{W_{k'}}^{W_{k'}} \chi \otimes 1) \oplus (\omega_{k'/k} \otimes \text{Sym}^{2}) \colon Sp(4)
\]

Here the Langlands parameter associated to \( \chi \) is also written by \( \chi \). \( \psi_{k', \chi} \) is an \( A \)-parameter of Soudry type.

## 7 Conjecture of Hiraga and Saito

Let \( F \) be a local field of characteristic 0 and \( \Gamma = \text{Gal}(\overline{F}/F) \). Rewrite \( G^{*} = Sp(4) \). We have the following bijection [8].

\[
\{\text{inner forms of } G^{*}\}/\sim \approx H^{1}(F, G^{*}_{\text{ad}})_{\psi} \quad G' \leftarrow u_{G'} : \Gamma \ni \gamma \mapsto \eta_{G'}^{-1} \circ \eta_{G'}^{\psi}
\]

Here \( \sim \) means isomorphy and \( \eta_{G'} : G^{*}(\overline{F}) \to G'(\overline{F}) \) is an inner twist. In addition, if \( F \) is non-archimedean then from [6]

\[
H^{1}(F, G^{*}_{\text{ad}}) \approx \pi_{0}(Z(G^{*}_{\text{sc}})^{\Gamma})_{\psi} \quad u_{G'} \leftarrow \chi_{G'}
\]
Here $\hat{G}_{\text{sc}}^{\ast}$ is the simply connected cover of $\hat{G}^{\ast} = SO(5, \mathbb{C})$ so that $\hat{G}_{\text{sc}}^{\ast} = Sp(4, \mathbb{C})$ and $(\ )^{D}$ means Pontrjagin dual. Write $j_{\text{sc}} : \hat{G}_{\text{sc}}^{\ast} \rightarrow \hat{G}^{\ast}$ for the covering map. The local Langlands group $L_{F}$ is defined by

$$L_{F} = \begin{cases} W_{F} \times SU(2, \mathbb{R}) & F : \text{non-archimedean}, \\ W_{F} & F : \text{archimedean}, \end{cases}$$

where $W_{F}$ is the Weil group of $F$. A local $A$-parameter $\psi : L_{F} \times SL(2, \mathbb{C}) \rightarrow L^{G^{\ast}}$ is defined similarly for the global case. For a local $A$-parameter $\psi$ and an inner form $G'$ of $G^{\ast}$ suppose the existence of local $A$-packet $\Pi_{\psi}^{G'}$ [2], which becomes a finite set of irreducible admissible representations of $G'(F)$. For a global or local $A$-parameter $\psi$, $S_{\psi}$ denotes $j_{\text{sc}}^{-1}(C_{\psi})$. $S_{\psi}$ is defined by $\pi_{0}(S_{\psi}) = S_{\psi}/S_{\psi}^{0}$. For an inner form $G'$ of $G^{\ast}$ the following condition is called the relevance condition for $(G', \psi)$:

$$\text{Ker} \chi_{G'} \supset Z(\hat{G}_{\text{sc}}^{\ast})^{\Gamma} \cap S_{\psi}^{0}.$$ 

Since

$$Z_{\psi}^{\Gamma} := \text{Im}(Z(\hat{G}_{\text{sc}}^{\ast})^{\Gamma} \rightarrow S_{\psi}) \cong Z(\hat{G}_{\text{sc}}^{\ast})^{\Gamma}/(Z(\hat{G}_{\text{sc}}^{\ast})^{\Gamma} \cap S_{\psi}^{0}),$$

if $(G', \psi)$ satisfies the relevance condition then $\chi_{G'}$ can be regarded as a character of $Z_{\psi}^{\Gamma}$. The conjecture of Hiraga and Saito is described as follows.

**Conjecture 7.1** ([3]). Let $F$ be non-archimedean. For a local $A$-parameter $\psi : L_{F} \times SL(2, \mathbb{C}) \rightarrow L^{G^{\ast}}$ there exists a pairing

$$\langle \ , \ \rangle_{F} : S_{\psi} \times \prod_{G' \in H^{1}(F,G^{\ast}_{\text{ad}})} \Pi_{\psi}^{G'} \rightarrow \mathbb{C}$$

which satisfies the following condition:

For any inner form $G'$ of $G^{\ast}$ there exists

$$\rho : \Pi_{\psi}^{G'} \rightarrow \Pi(S_{\psi}, \chi_{G'}) = \{ \text{irred. repre. $\sigma$ of } S_{\psi} \mid \sigma|_{Z_{\psi}^{\Gamma}} = \chi_{G'} \} / \sim$$

$$\omega \mapsto \omega$$

$$\tau \mapsto \rho_{\tau}$$

such that $\langle s, \pi \rangle_{F} = \text{Tr} \rho_{\pi}(s)$ for all $s \in S_{\psi}$.

If $F$ is non-archimedean then the set of inner forms of $G^{\ast}$ consists of $G^{\ast}$ and non-split group $G_{F}$. If $F$ is real it consists of $G^{\ast}$, $G_{F} = Sp(1,1)$ and compact group $Sp(4)$, and if $F$ is complex it consists of only $G^{\ast}$. In any case put $\Pi_{\psi}^{s} = \Pi_{\psi}^{G^{\ast}}$, $\Pi_{\psi}^{ns} = \Pi_{\psi}^{G_{F}}$, where $\Pi_{\psi}^{ns} = \emptyset$ if $F$ is complex. Since my results of residual spectrum and CAP representations (Theorem 4.1, 5.1, 6.1 and Proposition 6.2) do not contain the case of compact $Sp(4)$ at real place, we will forget the case of real $F$ and compact $Sp(4)$.

We will go back to the global case. For an elliptic $A$-parameter $\psi$ the associated local $A$-parameter $\psi_{v}$ is given for any place $v$ by the hypothetical homomorphism $L_{k_{v}} \rightarrow L_{k}$. Also homomorphism $S_{\psi} \rightarrow S_{\psi_{v}}$ is given. Assume that the pairing $\langle \ , \ \rangle_{\psi_{v}} : S_{\psi_{v}} \times (\Pi_{\psi_{v}}^{s} \cup \Pi_{\psi_{v}}^{ns}) \rightarrow \mathbb{C}$ satisfying the above conjecture is given for any $v$. Then the global pairing $\langle \ , \ \rangle = \prod_{v} \langle \ , \ \rangle_{v}$:
$S_{\psi} \times \Pi_{\psi}^{G} \rightarrow \mathbb{C}$ is defined. Let $\epsilon_{\psi} : S_{\psi} \rightarrow \{\pm 1\}$ be the character defined in [2]. For $\pi \in \Pi_{\psi}^{G}$ set

$$m_{\psi}(\pi) = \frac{1}{|S_{\psi}|} \sum_{s \in S_{\psi}} \epsilon_{\psi}(s) \langle s, \pi \rangle.$$

Arthur's multiplicity conjecture is described as follows.

**Conjecture 7.2** ([2]). The multiplicity of $\pi$ in $L_{disc}^{2}(G)$ is equal to $\sum_{\psi \in \Psi_{0}(G)} m_{\psi}(\pi)$.

### 8 Multiplicity Conjecture

The results of section 4, 5 and 6 give a speculation of the description of the multiplicity of non-tempered automorphic representations of $G(\mathbb{A})$. For an irreducible automorphic representation $\pi$ of $G(\mathbb{A})$ the multiplicity of $\pi$ in $L_{disc}^{2}(G)$ is denoted by $m(\pi)$.

**Expectation 8.1.**

1. (Saito-Kurokawa type) Suppose that an irreducible cuspidal representation $\sigma$ of $GL(2, \mathbb{C})$, a quaternion algebra $B$ and $\eta \in D$ satisfy the condition of Theorem 5.1, 1. Then $m(\Theta(\sigma, B, \eta)) = 1$.

2. (Soudry type)

$$m(\Theta(V, \chi, S)) = \begin{cases} 2^{2 |S_{\chi} \cap S_{D}| - 1} & \text{if } \chi^{2} \neq 1, S_{D} \cap S_{\chi} \neq \emptyset, \\ 2^{2 |S_{D}| - 2} & \text{if } \chi^{2} = 1, S_{D} \cap S_{\chi} \neq \emptyset, \\ 1 & \text{if } S_{D} \cap S_{\chi} = \emptyset. \end{cases}$$

These expected multiplicities can be rewritten in terms of Arthur's conjectural multiplicity. In other words, there is a pairing $\langle \cdot, \cdot \rangle$ such that $m(\pi) = m_{\psi}(\pi)$ for $\pi \in \Pi_{\psi}^{G}$ and all $\langle \cdot, \cdot \rangle_{v}$ satisfy the conjecture of Hiraga and Saito. Finally, we will see the discription.

#### 8.1 Saito-Kurokawa Type

An $A$-parameter $\psi$ of Saito-Kurokawa type is written by the form

$$\psi = \psi_{\sigma} = ((\phi_{\sigma} \otimes St) \oplus (1_{\mathcal{L}_{k}} \otimes 1_{SL(2, \mathbb{C})})) \times p_{k}$$

where $\sigma \simeq \bigotimes v \sigma_{v}$ is an infinite dimensional irreducible cuspidal representation of $PGL(2, \mathbb{A})$.

1. $v \notin S_{D}$

Write $V_{v}^{hyp}$ for the 4-dimensional hyperbolic quadratic space over $k_{v}$. $SO(V_{v}^{hyp})$ is isomorphic to

$$\{(g_{1}, g_{2}) \in GL(2, k_{v}) \times GL(2, k_{v}) \mid \det(g_{1}) = \det(g_{2})^{-1}\}/\{(z, z^{-1}) \mid z \in k_{v}^{\times}\}.$$

$\theta(\sigma_{v}, V_{v}^{hyp})$ denotes the Howe correspondent of $\text{Ind}_{SO(V_{v}^{hyp})}^{G^{(V_{v}^{hyp})}}(\sigma_{v} \otimes 1)$, which is an irreducible representation of $G(k_{v})$. Write $V_{v}^{an}$ for the 4-dimensional anisotropic quadratic space over $k_{v}$ if $v$ is non-archimedean, and $V_{v}^{\pm}$ for the 4-dimensional positive and negative definite quadratic spaces over $k_{v}$ if $v$ is real. Since the special orthogonal groups of these quadratic spaces are isomorphic to

$$\{(g_{1}, g_{2}) \in D_{k_{v}}^{\times} \times D_{k_{v}}^{\times} \mid \nu_{D_{k_{v}}}(g_{1}) = \nu_{D_{k_{v}}}(g_{2})^{-1}\}/\{(z, z^{-1}) \mid z \in k_{v}^{\times}\}$$
where $D_{k_v}$ is the quaternion division algebra over $k_v$, $\theta(JL(\sigma_v), V_{v}^{ani})$ and $\theta(JL(\sigma_v), V_{v}^{\pm})$ are defined similarly for $\theta(\sigma_v, V_{v}^{hyp})$. Here $JL(\sigma_v)$ is the Jacquet-Langlands correspondent of $\sigma_v$.

$$\Pi^s_{\psi_v} = \begin{cases} 
\{\tau_0 = \theta(\sigma_v, V_{v}^{hyp}), \tau_1 = \theta(JL(\sigma_v), V_{v}^{ani})\} & v : \text{non-arch. and } \phi_\sigma : \text{irreducible}, \\
\{\tau_0 = \theta(\sigma_v, V_{v}^{hyp}), \tau_1^\pm = \theta(JL(\sigma_v), V_{v}^{\pm})\} & v : \text{real and } \phi_\sigma : \text{irreducible}, \\
\{\tau_0 = \theta(\sigma_v, V_{v}^{hyp})\} & \text{otherwise}.
\end{cases}$$

Any $\tau_0$ is a quotient of $\text{Ind}_{P(k_v)}^{G(k_v)}(|\det|_v^{1/2}\sigma_v)$.

(2) $v \in S_D$

Write $V_{v}$ for the 2-dimensional skew-hermitian space over $D_v$ of determinant 1. Since $G(V_{v}) = G_0(V_{v})$ and $G_0(V_{v})$ is isomorphic to

$$\{(g_1, g_2) \in D_v^x \times GL(2, k_v) | \nu(g_1) = \det(g_2)^{-1}\}/\{(z, z^{-1}) | z \in k_v^x\}$$

the Howe correspondents $\theta(\sigma_v, V_{v})$ and $\theta(JL(\sigma_v), V_{v})$ are defined.

$$\Pi^{ns}_{\psi_v} = \begin{cases} 
\{\tau'_0 = \theta(\sigma_v, V_{v}), \tau'_1 = \theta(JL(\sigma_v), V_{v})\} & \phi_\sigma : \text{irreducible}, \\
\{\tau'_0 = \theta(\sigma_v, V_{v})\} & \phi_\sigma : \text{reducible}.
\end{cases}$$

$S_\psi \simeq \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ and

$$S_{\psi_v} \simeq \begin{cases} 
\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} & \phi_\sigma : \text{irreducible}, \\
\{1\} \times \mathbb{Z}/2\mathbb{Z} & \phi_\sigma : \text{reducible}.
\end{cases}$$

Define a pairing $\langle \cdot, \cdot \rangle_v$ as

$$\langle \cdot, \tau_\epsilon \text{ (or } \tau_\epsilon^\pm) \rangle_v = \text{sgn}^\epsilon \otimes 1 \text{ if } v \not\in S_D, \quad \langle \cdot, \tau'_\epsilon \rangle_v = \text{sgn}^\epsilon \otimes \text{sgn} \quad \text{ if } v \in S_D.$$

$$\epsilon_\psi = \begin{cases} 
1 & \epsilon(1/2, \phi_\sigma) = 1, \\
\text{sgn} \otimes 1 & \epsilon(1/2, \phi_\sigma) \neq 1,
\end{cases}$$

where $\epsilon(1/2, \phi_\sigma)$ is the value of Jacquet-Langlands $\epsilon$-function of $\sigma$ at 1/2. Then the Arthur’s conjectural multiplicity is described by

$$m_{\psi}(\pi) = \frac{1}{2}(1 + \epsilon(1/2, \phi_\sigma)\langle(-1,1), \pi\rangle) \quad (\pi \in \Pi^G_{\psi}).$$

If $\pi$ is represented by the form $\Theta(\sigma, B, \eta)$ satisfying the condition of Theorem 5.1,1 then $m_{\psi}(\pi) = 1$.

8.2 Soudry Type

An A-parameter $\psi$ of Soudry type is written by the form

$$\psi = \psi_{k', \chi} = \left(\text{Ind}_{W_{k'}}^{W_{k}}(\chi \otimes 1) \oplus (\omega_{k'/k} \otimes \text{Sym}^2)\right) \times p_k,$$
for some $k'$ and $\chi$.

(1) $v \notin S_D$

$$\Pi_{\psi_v}^s = \begin{cases} 
\{\theta(V_v^\pm, \tilde{\chi}_v)\} & \chi_v^2 \neq 1 \text{ and } \delta_v \neq -1, \\
\{\theta(\mathbb{H}_v, \tilde{\chi}_v)\} & \chi_v^2 \neq 1 \text{ and } \delta_v = -1, \\
\{\theta(V_v^\pm, \tilde{\chi}_v^\pm)\} & \chi_v^2 = 1 \text{ and } \delta_v \neq -1, \\
\{\theta(\mathbb{H}_v, \tilde{\chi}_v^\pm)\} & \chi_v^2 = 1 \text{ and } \delta_v = -1. 
\end{cases}$$

Here $V_v^\pm$ is the two-dimensional quadratic space over $k_v$ with determinant $\delta$ and Hasse invariant $\pm 1$, $\mathbb{H}_v$ is the two-dimensional hyperbolic space over $k_v$, and $\theta(V_v, \lambda_v)$ denotes the Howe correspondent of the representation $\lambda_v$ of $G(V_v)$. The correspondent from $\tilde{\chi}_v$ is supercuspidal and the others are of the form of a quotient of $\text{Ind}_{\text{P}_K(k_v')}^{\text{Sp}(2k_v)}(\omega_{k_v'}/k_v \cdot \| \otimes \tau_v)$ for some irreducible representation $\tau_v$ of $SL(2, A)$.

(2) $v \in S_D$

$$\Pi_{\psi_v}^{ns} = \begin{cases} 
\{\theta(V_v, \chi_v), \theta(V_v, \chi_v^{-1})\} & \chi_v^2 \neq 1, \\
\{\theta(V_v, \chi_v)\} & \chi_v^2 = 1.
\end{cases}$$

Elements of $\Pi_{\psi_v}^{ns}$ are supercuspidal except for $\chi_v = 1$.

$$S_{\psi} \simeq \begin{cases} 
\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} & \chi^2 \neq 1, \\
D_4 & \chi^2 = 1,
\end{cases}$$

where $D_4$ is the dihedral group with 8 elements. If $k_v'$ is a quadratic extension of $k_v$ then

$$S_{\psi_v} \simeq \begin{cases} 
\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} & \chi_v^2 \neq 1, \\
D_4 & \chi_v^2 = 1,
\end{cases}$$

and if $k_v' \simeq k_v \oplus k_v$ then

$$S_{\psi_v} \simeq \begin{cases} 
\{1\} & \chi_v^2 \neq 1, \\
\mathbb{Z}/2\mathbb{Z} & \chi_v^2 = 1.
\end{cases}$$

Define a pairing $\langle \cdot, \cdot \rangle_v$ as follows. If $v \in S_D$ and $\chi_v^2 = 1$ then

$$\langle s, \theta(V_v, \chi_v) \rangle_v = \begin{cases} 
2s = \pm 1 & s = \pm 1, \\
0 & \text{otherwise},
\end{cases}$$

and otherwise

$$\langle \cdot, \theta(V_v^\eta, \tilde{\chi}_v^\epsilon) \rangle_v = \text{sgn}^\epsilon \otimes \text{sgn}^\eta,$$

where we regard $\mathbb{H}_v = V_v^+$ and $\tilde{\chi}_v = \tilde{\chi}_v^+$. In case of Soudry type, $\epsilon_\psi = 1$. Then the Arthur's conjectural multiplicity is described by an irreducible automorphic representation $\pi \in \Pi_{\psi_G}^G$,

$$m_\psi(\pi) = \begin{cases} 
2^{|S_v \cap S_D|-2} & \chi^2 \neq 1, \ S_D \cap S_x \neq \emptyset, \\
2^{|S_D|-2} & \chi^2 = 1, \ S_D \cap S_x \neq \emptyset, \\
1 & \text{if } S_D \cap S_x = \emptyset.
\end{cases}$$
