# The 1st Italian “hazard” map (1968)

## Seismic zones according to the 1900-1964 seismicity

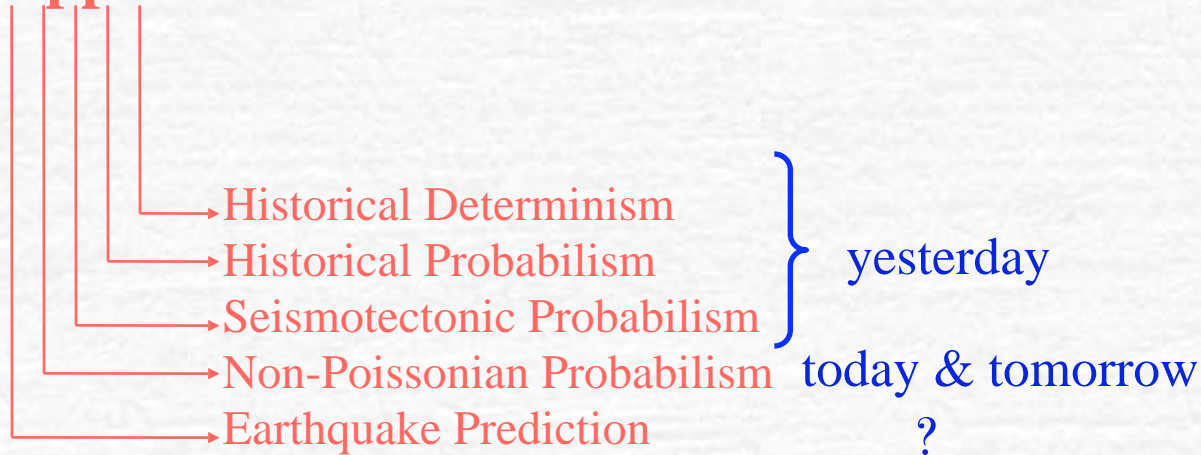

from “La Domenica del Corriere”  
(courtesy Franco Pettenati)

# Generations of hazard maps

Yesterday: 1st Generation - Historical Determinism

## Approaches

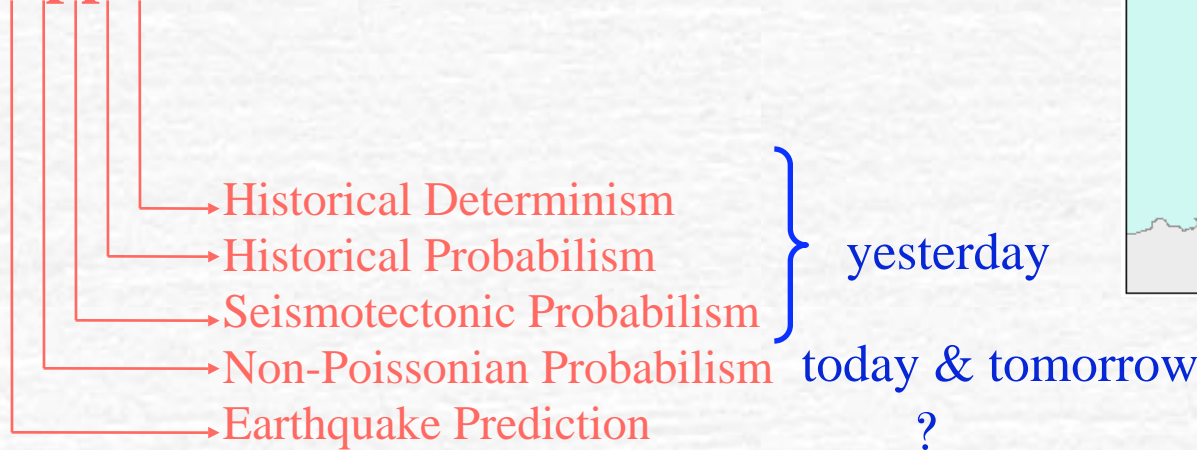

(Muir-Wood, 1993)

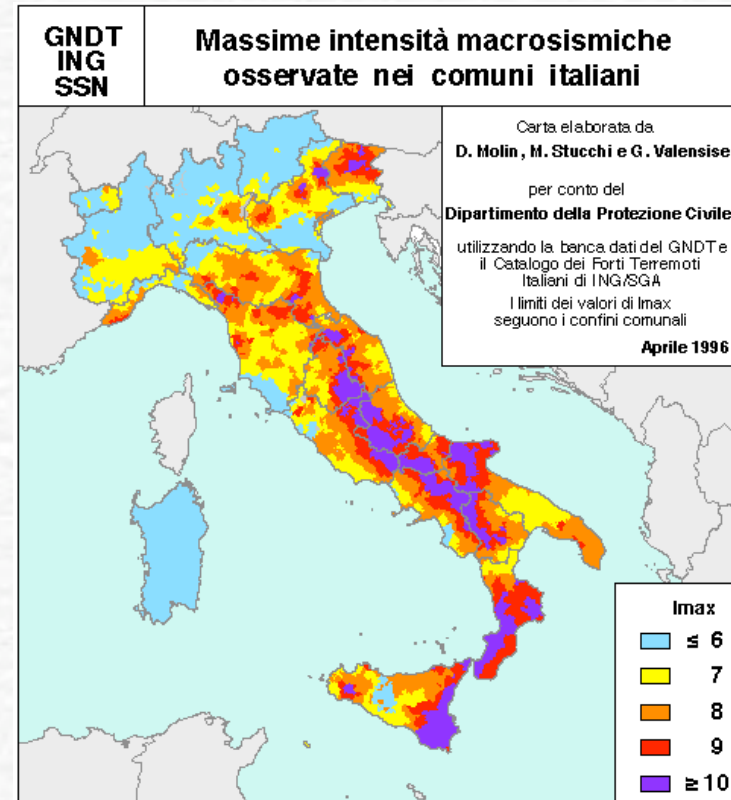

# Generations of hazard maps

Yesterday: 1st Generation - Historical Determinism

## Approaches

(Muir-Wood, 1993)

# Yesterday late 70's: 2nd Generation - Historical Probabilism

## The Gumbel approach

Given  $I_{max} = \max X_i$ , with  $i=1, \dots, n$  and  $n$  large

Type 1: no upper limit of  $X_i$

$$P[I_{max} \geq i] = F_{I_{max}}(i) = \exp[-e^{-\alpha(i-u)}]$$

Type 3: upper limit of  $X_i$

$$P[I_{max} \geq i] = F_{I_{max}}(i) = \exp\{-[(w-i)/(w-u)]k\}$$

## Application

Putting  $F_X(x) = i/(n+1)$

Introducing the reduced variable

$$y_i = -\ln\{-\ln[F_X(x_i)]\}$$

$$y_i = \alpha(x_i - u)$$

Seismic hazard map (CNR, 1979) used as basis of the 1980 Italian seismic zonation

## The Cornell (1968) approach

The total probability theorem  $P[E] = \int P[E | S] f_s(s) ds$

where  $f_s(s) = \partial F_s(s) / \partial s$  is the PDF of S

and  $F_s(s) = P[S < s]$  is the CDF of S

### Application

Mean annual rate of exceedence

$$\lambda_z = \sum_{i=1}^N v_i \int_{m_0}^{m_u} \int_{r=0}^{r=\infty} P(Z > z | m, r) f_i(m) f_i(r) dr dm$$

for all SZs

Mean annual rate of occurrence

Attenuation model

GR distribution

SZ geometry

If it is a Poisson process (stationary, independent, non-multiple events)

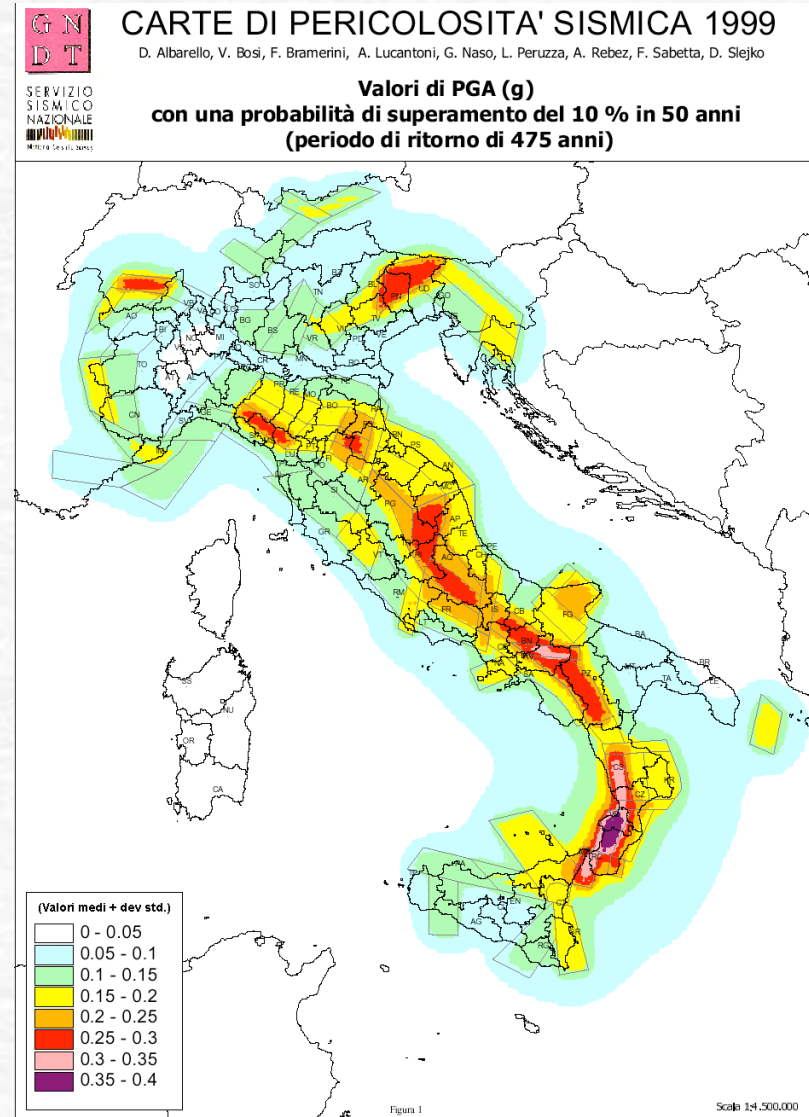

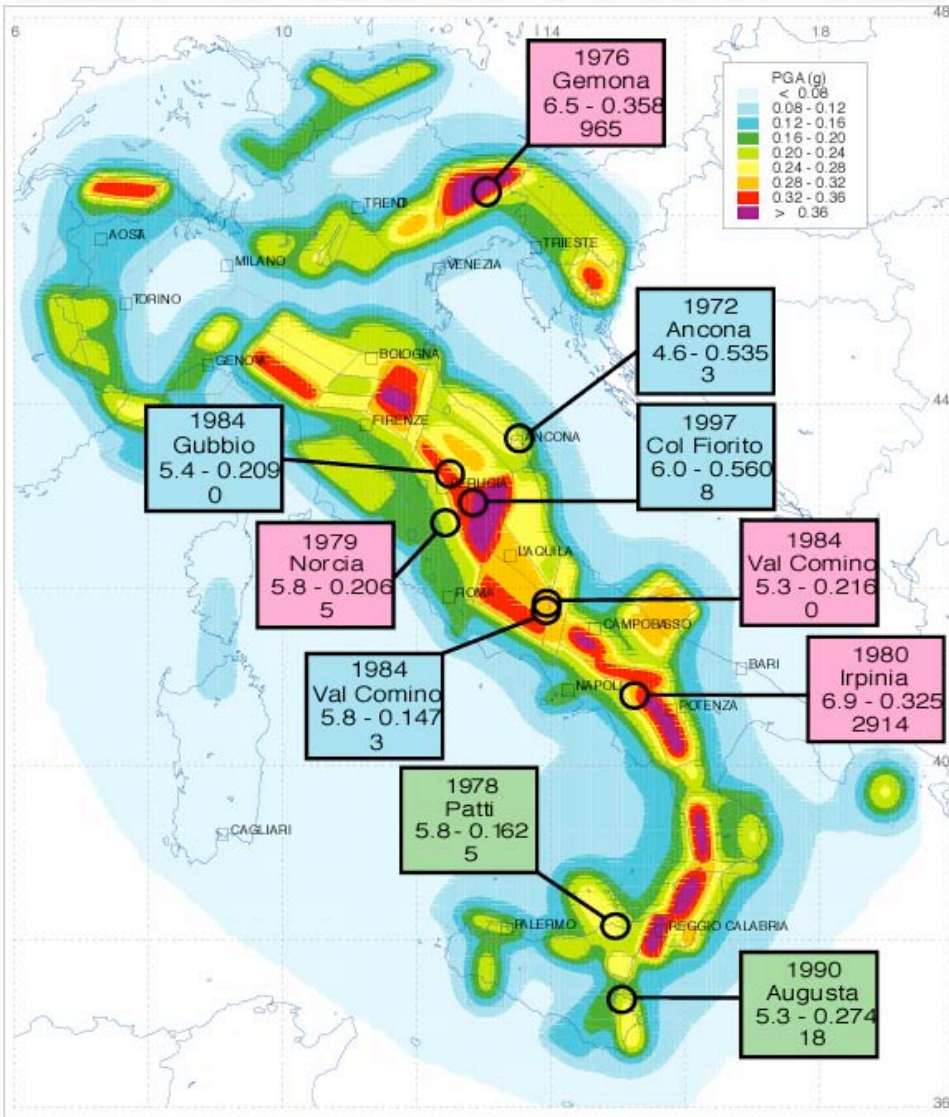

$$P[Z_T > z] = 1 - e^{-\lambda_z T}$$

$$T = -t / \ln(1 - P(Z_T > z))$$

where: T=return period;  
t=period of analysis

# Today 2004: The GNDT/Amato Project (2000-2004)

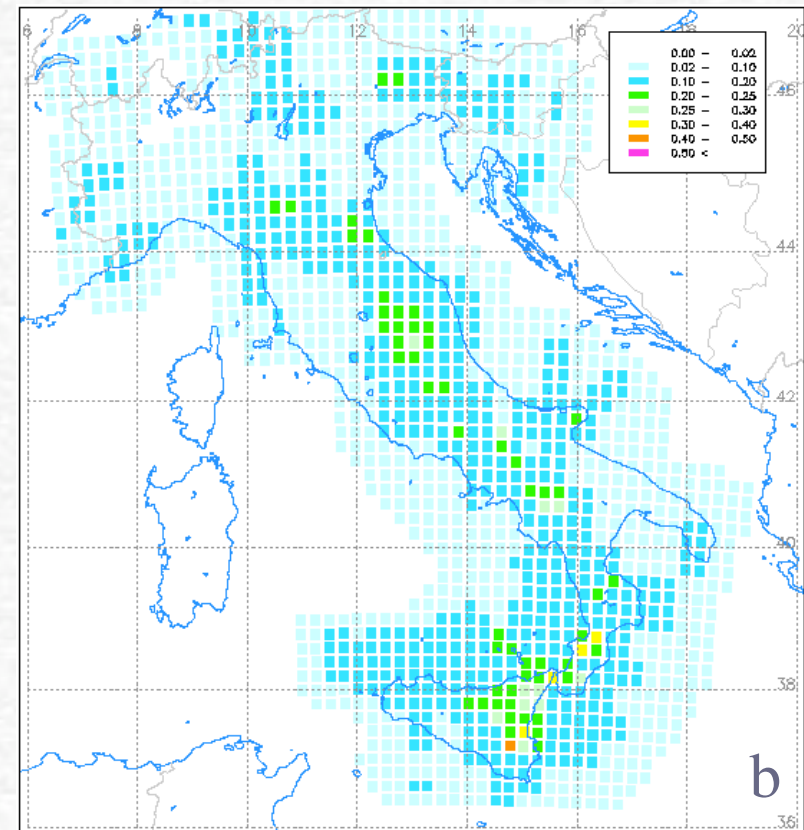

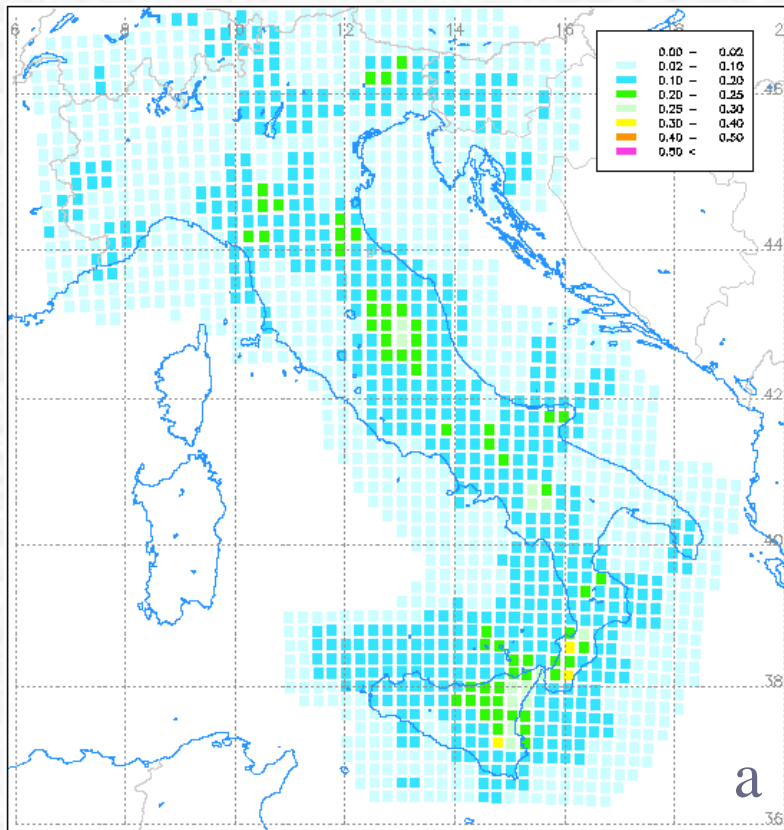

a) Seismogenic sources (Valensise and Pantosti, 2001)

b) Occurrence probability of the characteristic eq on the seismogenic sources  
(from Peruzza, 2006)

# Today 2004: The GNDT/Amato Project (2000-2004)

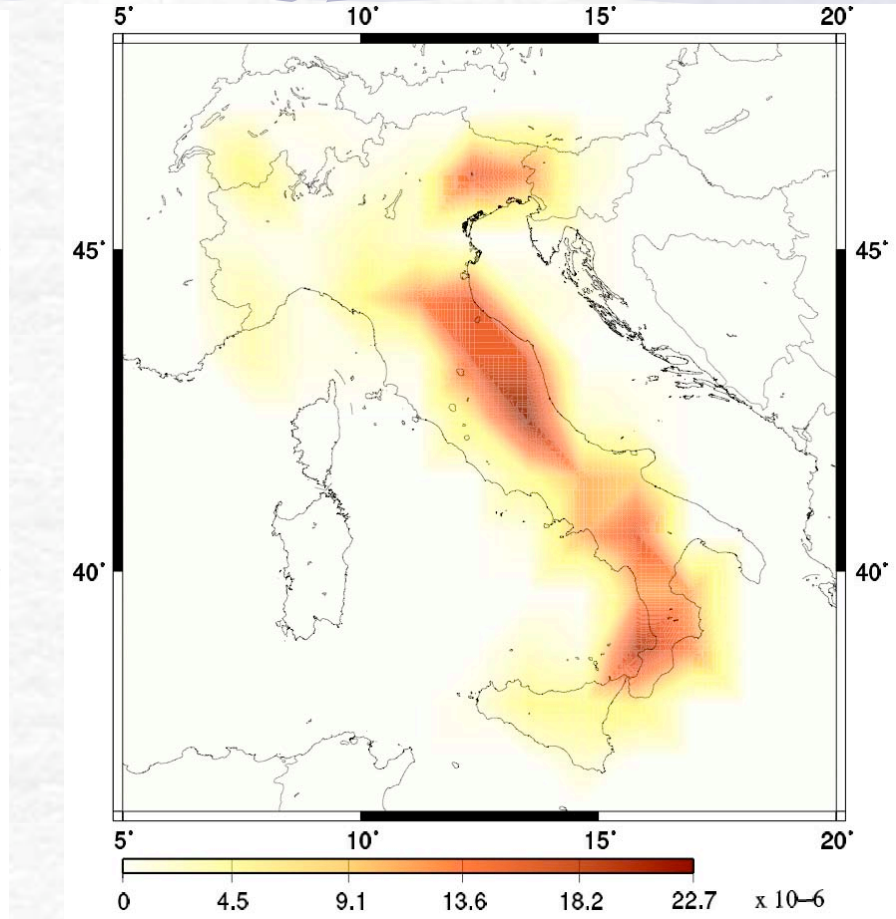

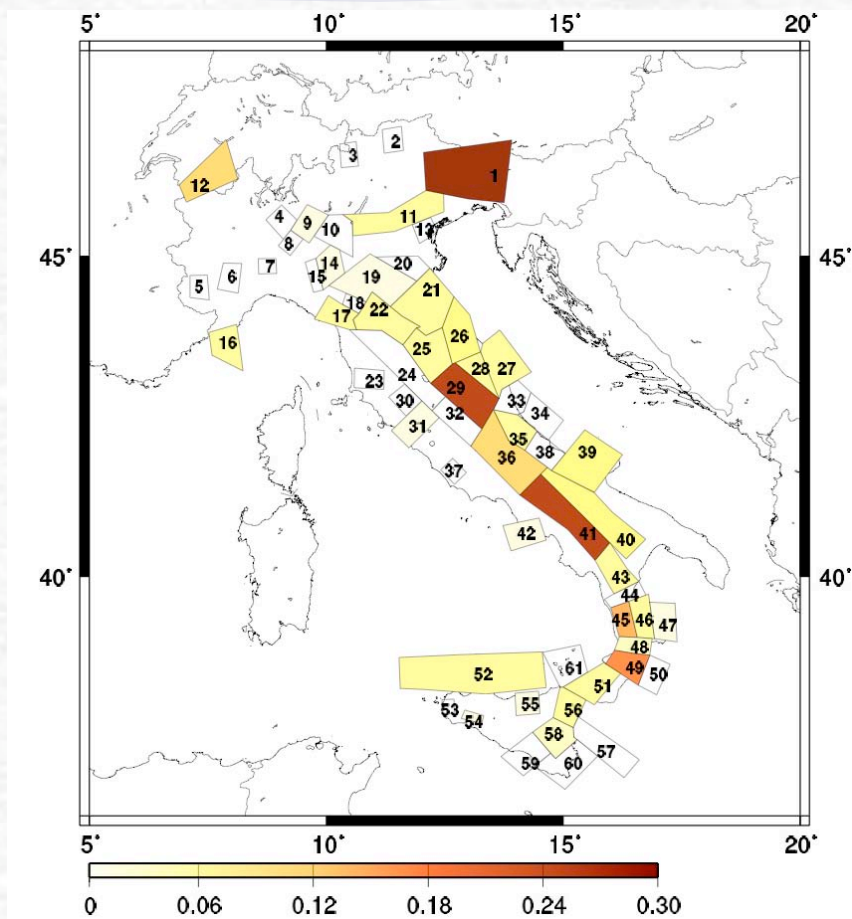

PGA with a 90% probability of exceedence in the period 2003-2033:  
a) Poisson model; b) time-dependent model (Peruzza, 2006)

# Today 2007: Occurrence probability of next M 5.5+ eq for the next 10 yrs

[www.bo.ingv.it/~earthquake/ITALY/forecasting/M5.5+/](http://www.bo.ingv.it/~earthquake/ITALY/forecasting/M5.5+/)

The two maps are calculated by using the same statistical procedure (Faenza et al., 2003; Cinti et al., 2004) applied to a seismotectonic zonation (a) and to a regular grid (b). The probability maps are updated every 1st of January and after the occurrence of a new target eq.

# Do characteristic eqs exist? (1)

1805 Bojano Basin, M 6.7

1908 Messina Straits, M 7.1

Evidence from significant ( $M \geq 6$ ) dip-slip Italian eqs suggests that:

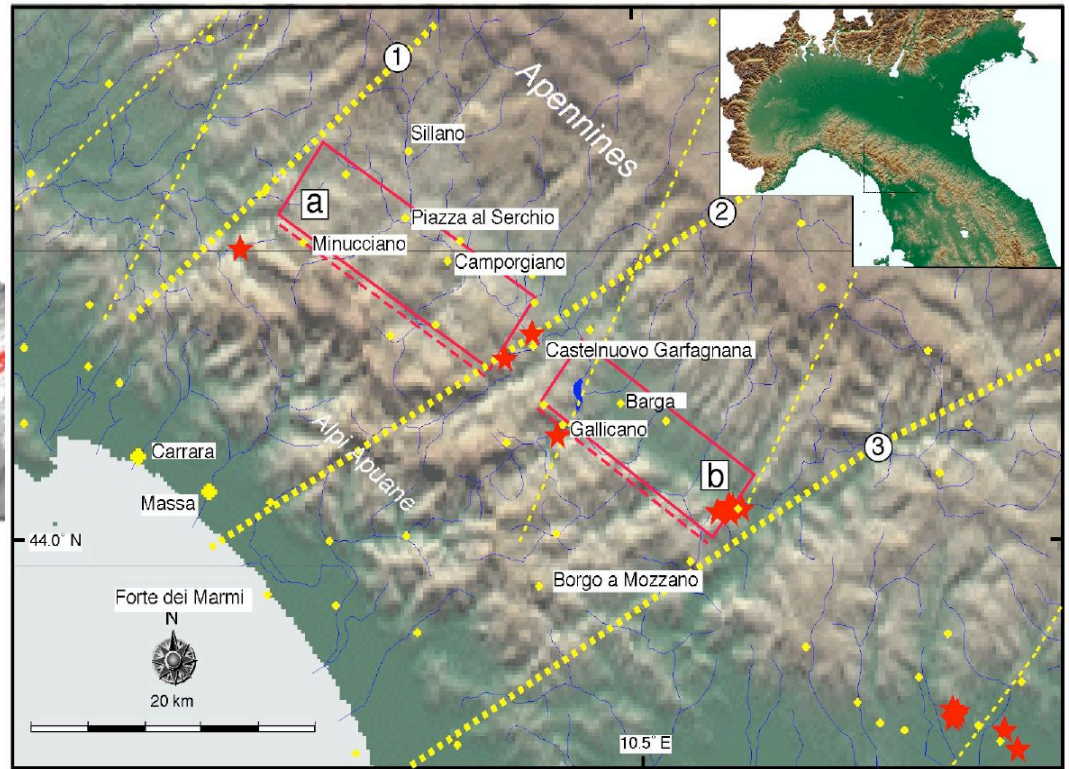

- ✓ earthquake ruptures tend to mimic geological domains and large landscape features

# Do characteristic eqs exist? (2)

1920 Garfagnana, M 6.5

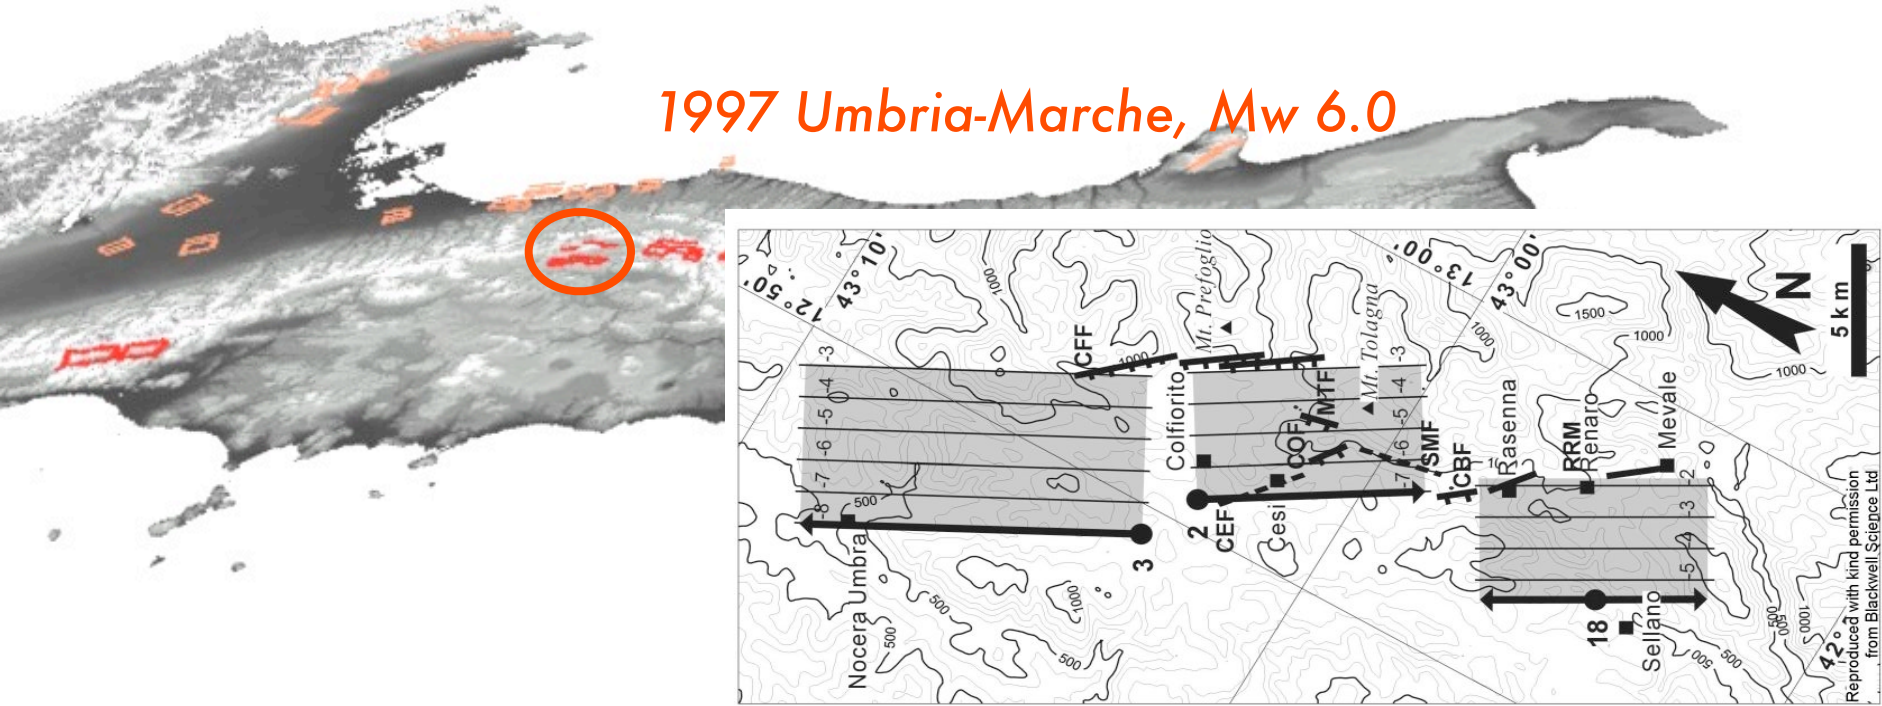

Evidence from significant ( $M \geq 6$ ) dip-slip Italian eqs suggests that:

- ✓ earthquake ruptures tend to coincide with singularities of the tectonic fabric

# Do characteristic eqs exist? (3)

## 1997 Umbria-Marche, Mw 6.0

Evidence from significant ( $M \geq 6$ ) dip-slip Italian eqs suggests that:  
✓ eq ruptures tend to be juxtaposed but never overlap

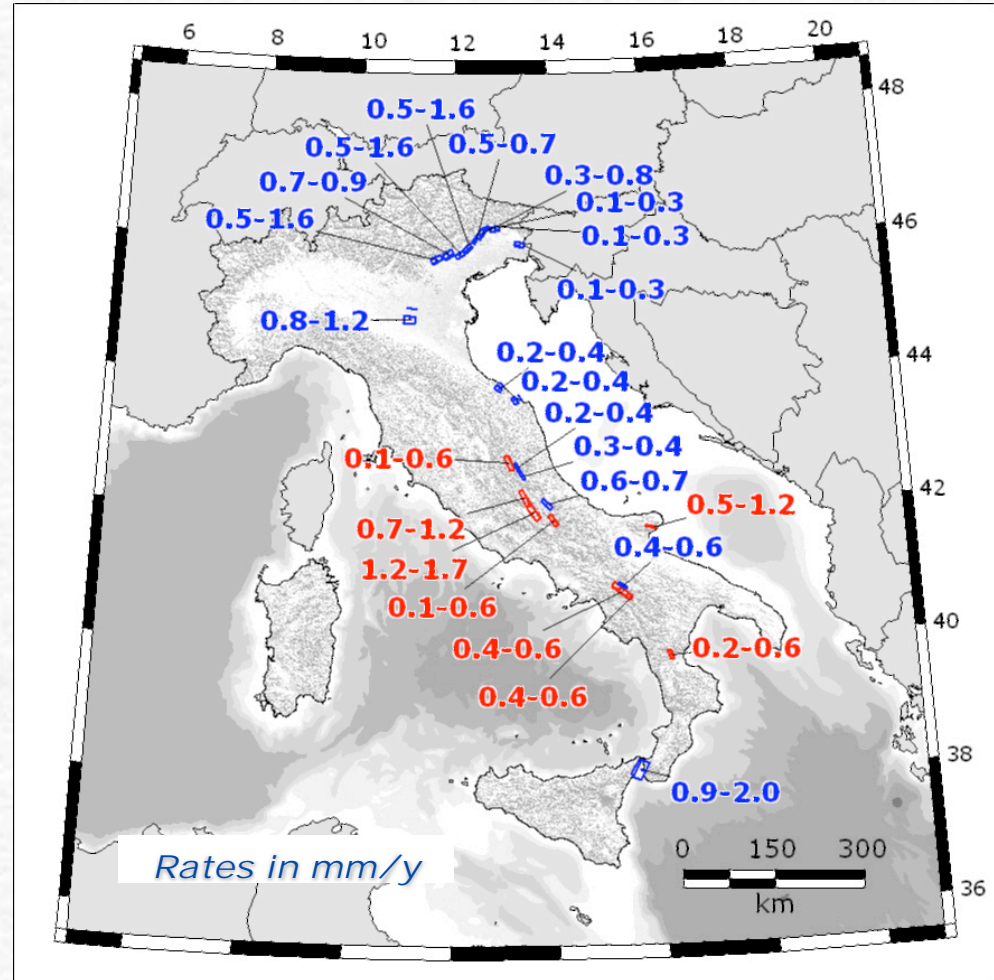

# Do characteristic eqs exist? (4)

- ✓ Growing geological evidence shows that the rupture length of Italian dip-slip eqs - and hence their  $M$  - coincides with the characteristic length of large-scale geological structures.
- ✓ The existing geologic fabric exerts a strong control over the fragmentation of active deformation/fault zones, effectively putting a (predictable) upper bound to the  $M_{\max}$  of individual rupture episodes.
- ✓ Rupture complexity due to fault interaction may make things appear more random than they are. To further confuse then issue, growing historical and instrumental evidence is suggesting that the majority of Italian eqs are complex in one way or the other.
- ✓ Large-scale geological evidence obviously does not control, nor contain any information on, the timing of subsequent eqs.
- ✓ The debate on characteristic eqs is dominated by evidence from strike-slip faults and subduction zones. Dip-slip faulting follows different rules.

# Recurrence of Italian earthquakes - Slip rates

Most Italian faults are blind and hence hard to investigate. Direct observations of slip rate (e.g. trenching, **in red**) exist for about 10 faults. 15-20 additional estimates were obtained through indirect observations (deformation of recent geologic horizons, of marine and fluvial terraces, subsurface data, **in blue**)

# Recurrence of Italian earthquakes - Interevent times

Interevent times exist only for very few faults. The causative faults of the 1980 Irpinia (top) and 1915 Avezzano (bottom) eqs yield the most complete records available countrywide. Typical recurrence intervals for the other faults is longer than several centuries (often >1,000 years), in agreement with historical record.

## Progetto S2: Valutazione del potenziale sismogenetico e probabilità dei forti terremoti in Italia

### Project S2: Evaluation of the seismogenic potential and occurrence probability of large

- Task 1.** Construction of a database for the seismogenesis (DISS).
- Task 2.** Spatial definition of the main seismogenic structures.
- Task 3.** Geophysical characterization of the main seismogenic structures.
- Task 4.** Seismic characterization of the main seismogenic structures and assessment of eq occurrence probability.

#### *Deliverables for application*

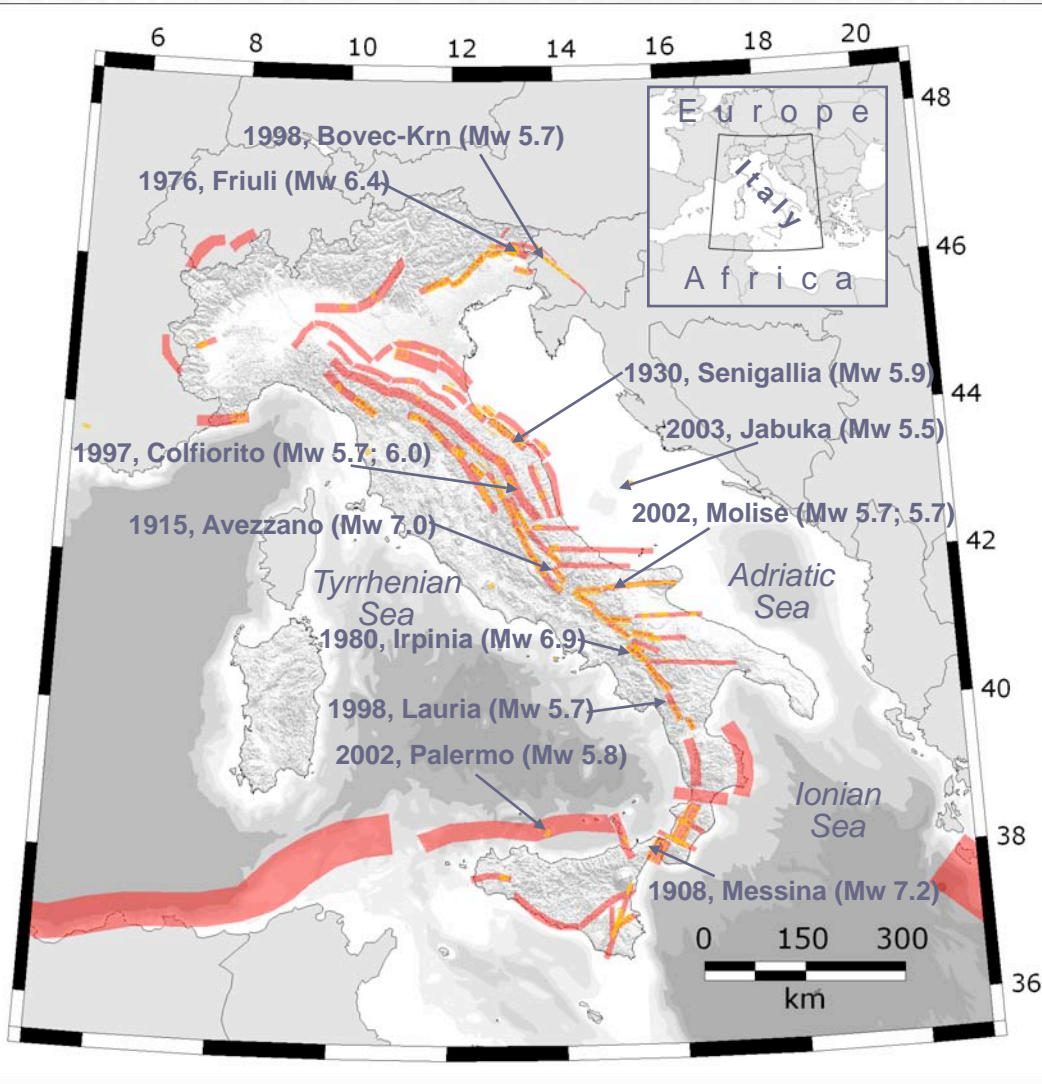

- 1) Database of the Italian M5.5+ seismogenic sources (SSs and SAs) with all geological and seismological information (DISS);
- 2) Map of the seismogenic sources with Mmax and, when possible, with recurrence interval;
- 3) Maps of tsunami wave height along the Italian coasts.

#### *Research Deliverables*

- Monographs of the SSs and SAs;
- Code Boxer (for treatment of macroseismic data);
- Database EMMA of focal mechanisms of the Mediterranean region;
- Maps of velocity and strain-rate from GPS data;
- Maps of velocity and strain-rate from 3D numerical modelling.

# Tomorrow: Task 1 & 2 - the DISS database

## Individual Seismogenic Source (SS)

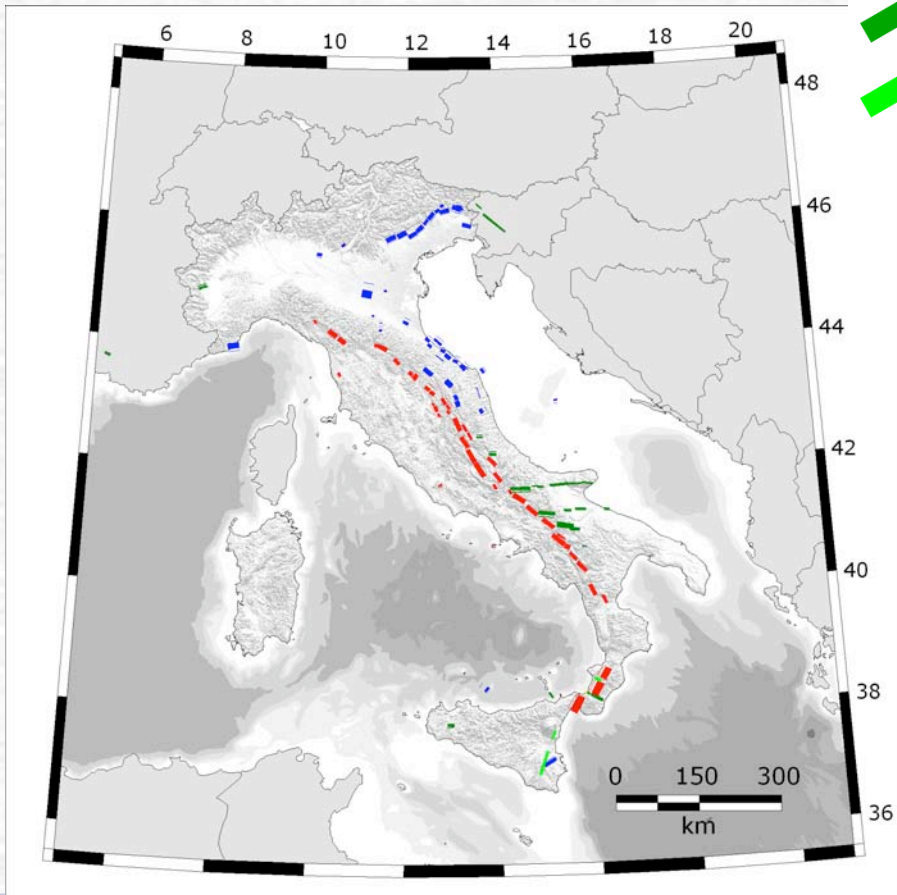

## Seismogenic Area (SA)

# Tomorrow: The DISS database

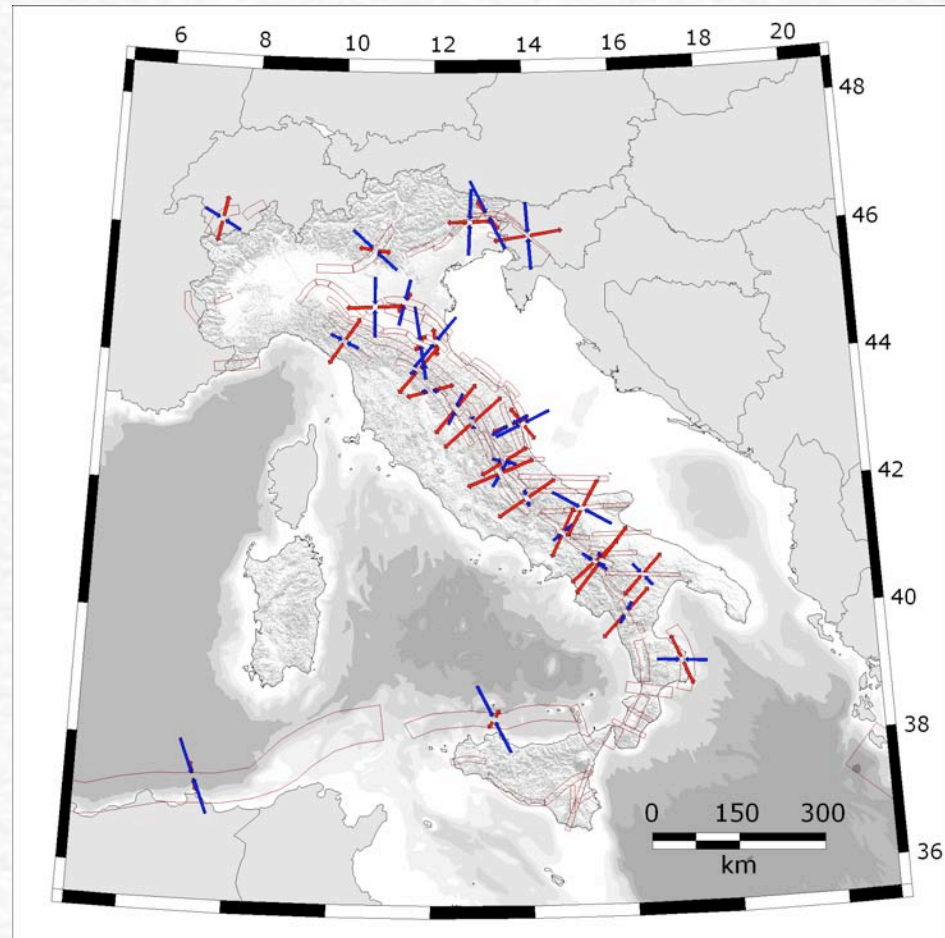

## Faulting mechanisms of the seismogenic sources and areas

- Normal
- Reverse
- Dextral
- Sinistral

# Tomorrow: The DISS database

## Average focal mechanisms in the SAs

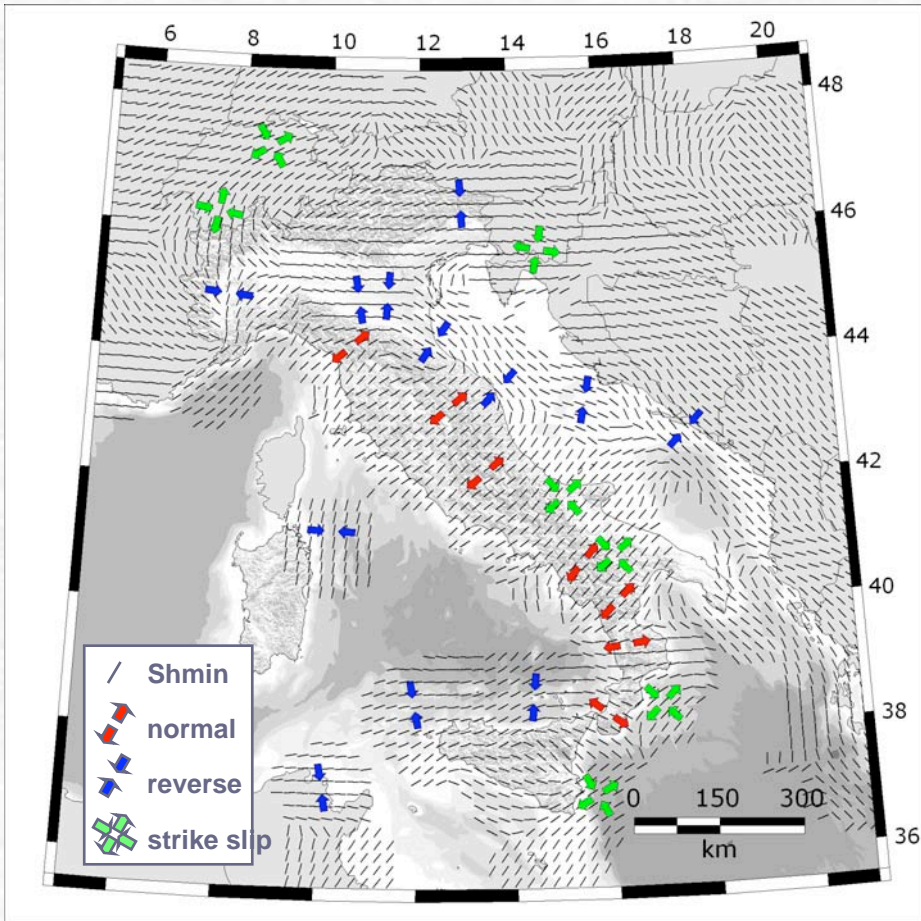

Average focal mechanism in the SA

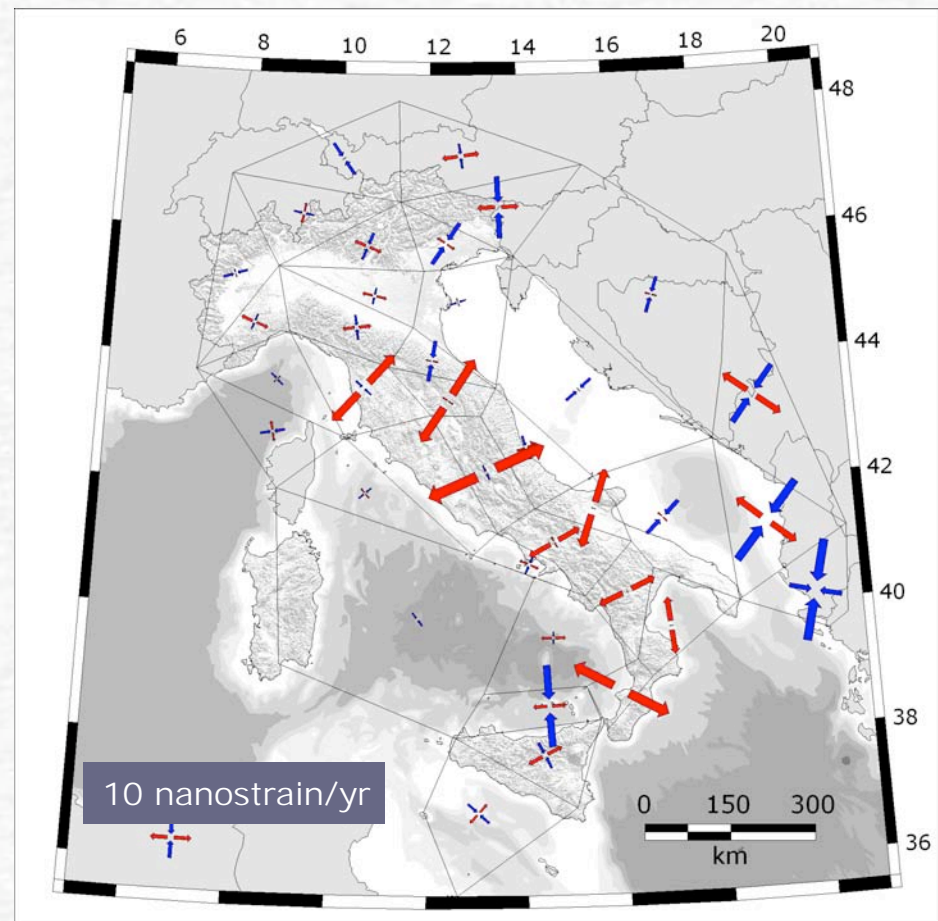

P and T axes from moment tensor summation of eqs in the SA

# Tomorrow: The DISS database Stress and strain regime in the SAs

Smoothed Shmin orientation and stress regime

Horizontal strain rates

Tomorrow: Task 3

# Obtaining strain rates for all Italian fault zones

## Three strategies:

- 1) regional measurements;
- 2) national strain map;
- 3) geodynamic modelling.

## Main result:

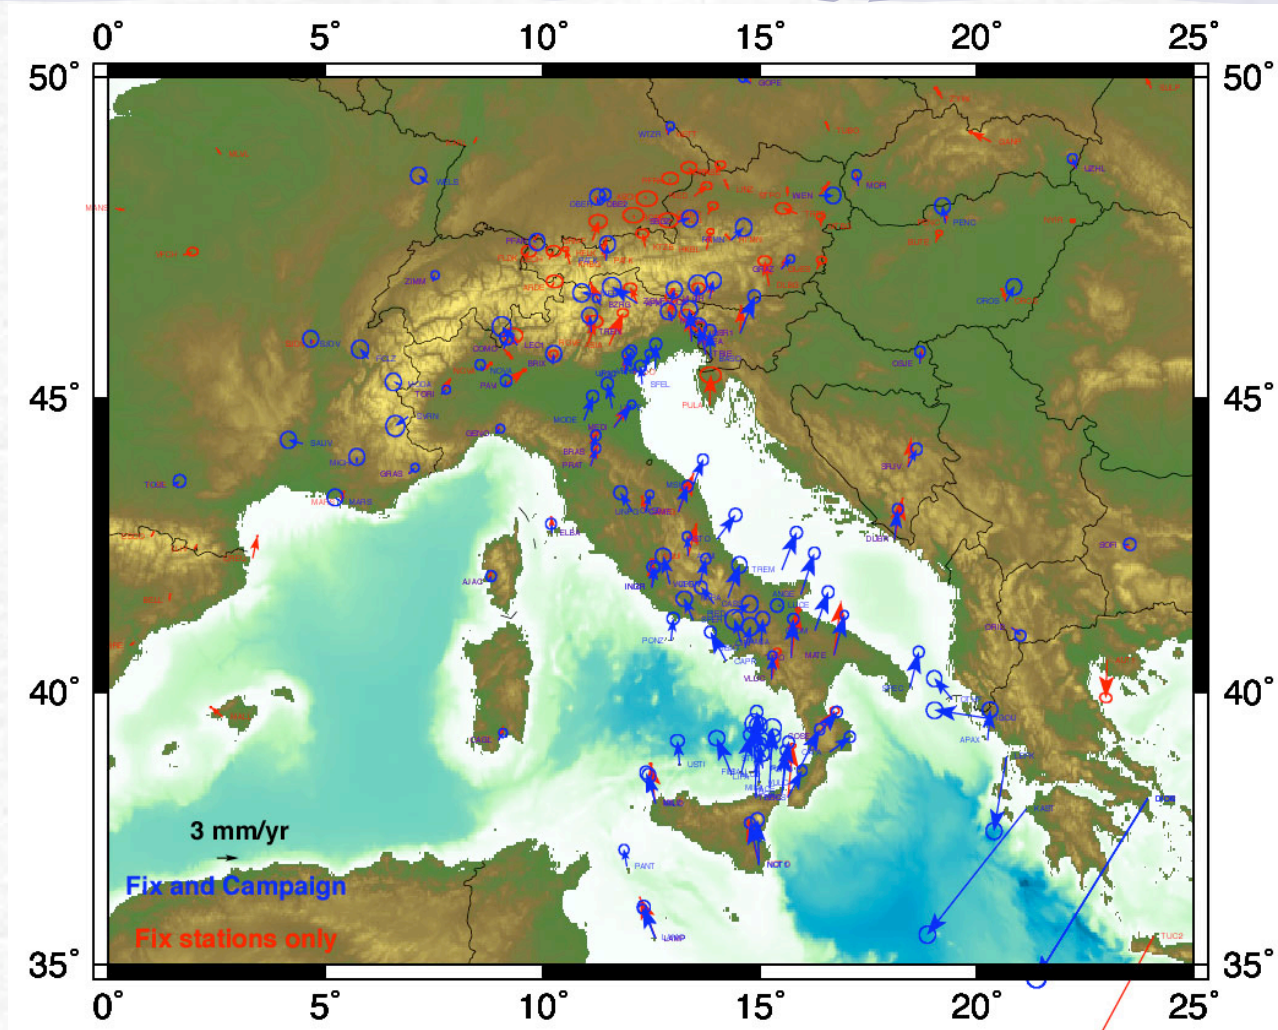

Estimation of the strain rate for all sources (SSs or SAs) in the Italian peninsula

# Tomorrow: Task 3

## National strain map

Velocities measured by permanent and additional stations

## Tomorrow: Task 3 Geodynamic modelling

The best fitting model has been selected using:

- GPS displacements;
- SHmin orientation from break-out and eqs;
- tectonic regime in DISS SAs

Finite elements numerical modelling  
Software SHELLS (Bird, 1999)  
Boundary conditions:  
blue = Adria rotation;  
red = Africa compression;  
violet = basal tractions  
black = fixed

Triangular grid (black) and faults (red)  
of the physical model

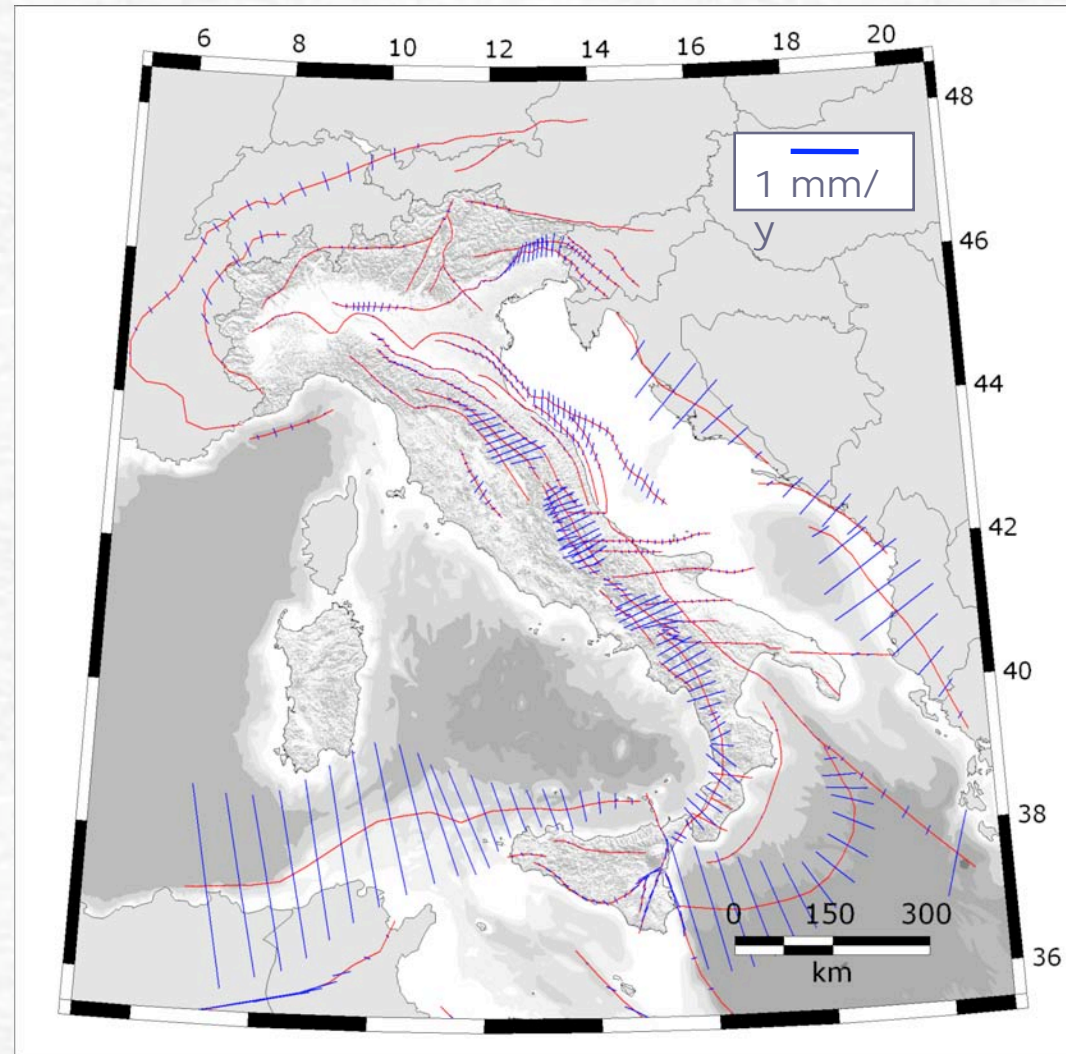

# Geodynamic modelling

## Slip rates predicted along model discontinuities

With this model, anelastic slip rates and moment rates are computed.

The behaviour of areas that do not include large faults or where  $M < 5.5$  eqs dominate must be derived from the strain-rate directly.

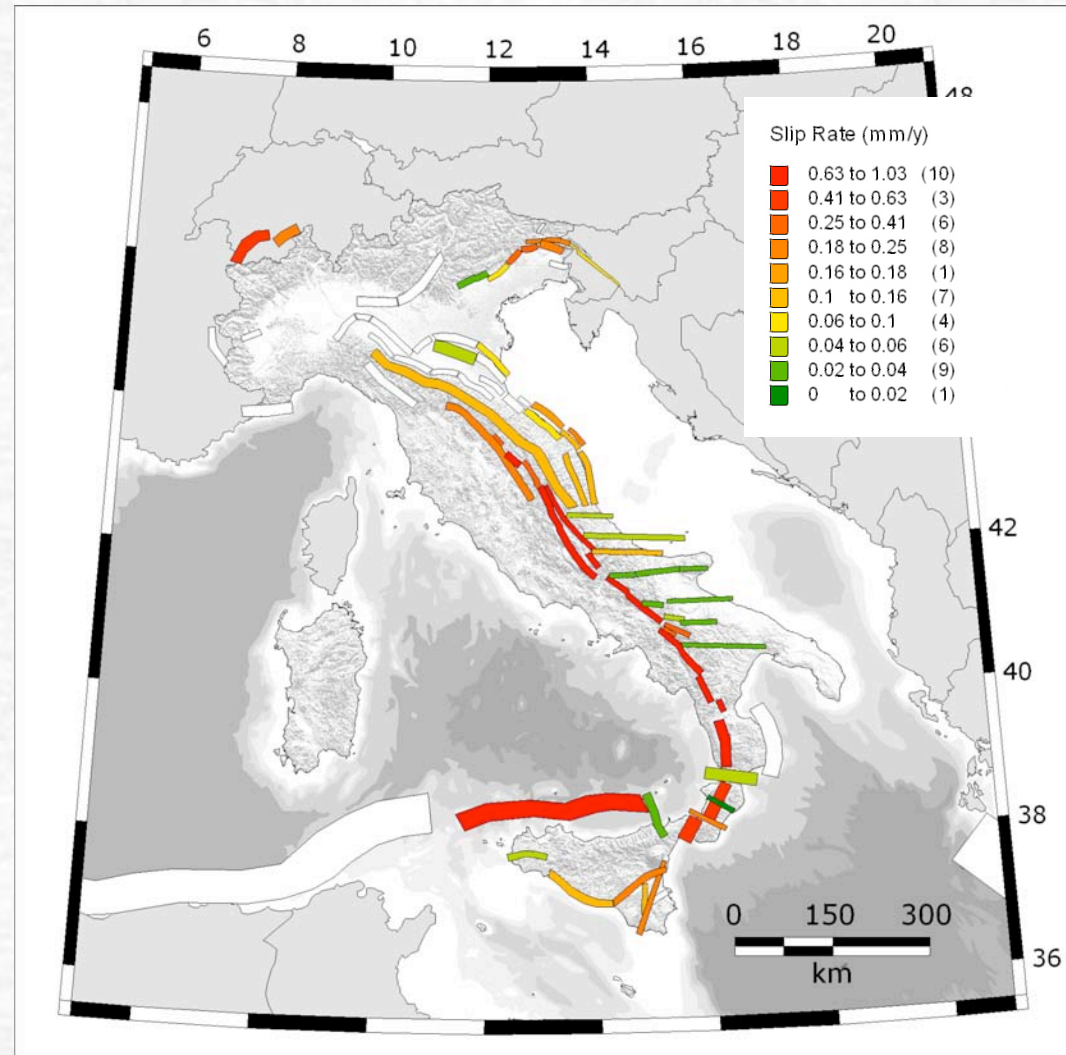

Anelastic slip rates can be compared with observed (geological) slip rates.

# Geodynamic modelling

## Predicted slip rates spread over the SAs

Anelastic slip rates are averaged within the SAs in order to gain stability. This first-order picture can ideally be checked against patterns of occurrence of large earthquakes. White areas are not determined

1) Probability of an imminent earthquake using instrumental data-sets of events

2) Occurrence probabilities supported by physical model

3a) Probabilities of main events based on inter-times derived from areas

3b) Probabilities of main events based on fault data

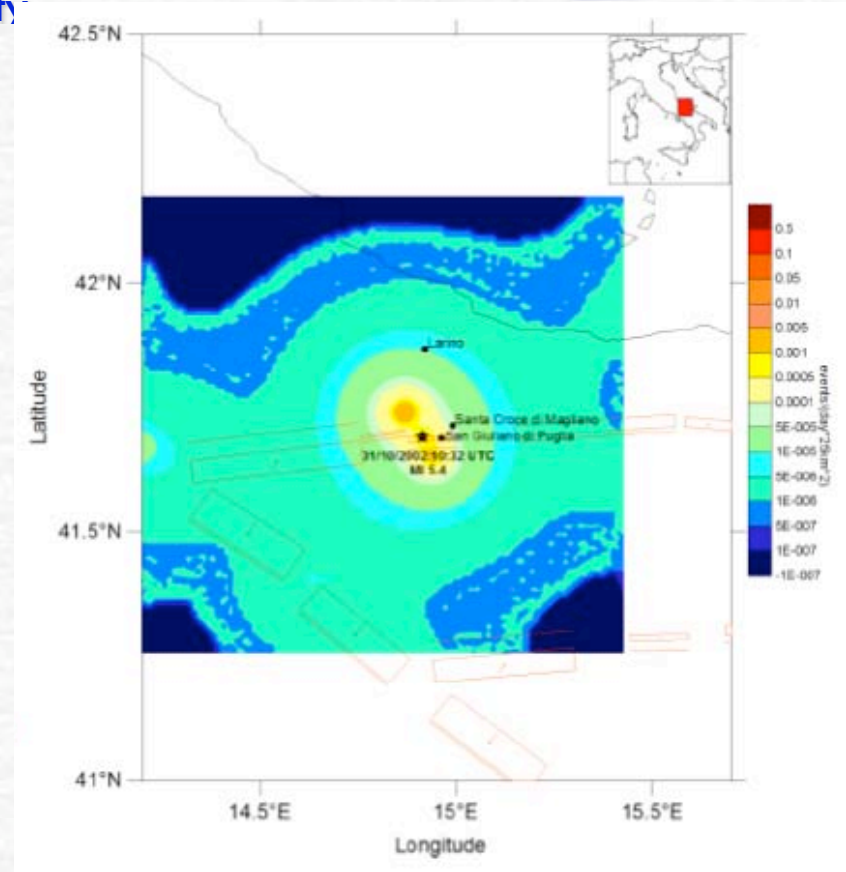

# Seismic characterization of the main seismogenic structures and assessment of eq occurrence probability

1) Probability of an imminent earthquake using instrumental data-sets of events

2) Occurrence probabilities supported by physical model

3a) Probabilities of main events based on inter-times derived from areas

3b) Probabilities of main events based on fault data

Occurrence rate increment before San Giuliano mainshock ( ETAS model)

1) Probability of an imminent earthquake using instrumental data-sets of events

2) Occurrence probabilities supported by physical model

3a) Probabilities of main events based on inter-times derived from areas

3b) Probabilities of main events based on fault data

Seismic characterization of the main seismogenic structures and assessment of eq occurrence probability

1) Probability of an imminent earthquake using instrumental data-sets of events

2) Occurrence probabilities supported by physical models Contribution of fault interaction

	Ovindoli-Pezza	Sulmona Basin	Fucino Basin	Aremogna-Cinquemiglia
<b>R<sub>0</sub> Poisson</b>	6.25e-04	1.18e-03	7.14e-04	4.67e-04
<b>R<sub>0</sub> cond</b>	4.29e-03	1.33e-04	5.00e-04	4.07e-03
<b>R<sub>0</sub> mod</b>	5.90e-03	1.32e-04	5.00e-04	4.40e-03
<b>Delta_t (anni)</b>	+63.00	-53.00	0.00	+21.30
<b>P(30)Poisson (DISS 3.0.1)</b>	1.90%	3.50%	2.10%	1.40%
<b>P(30)cond (Peruzza, comm. pers.)</b>	12.10%	0.40%	1.50%	11.00%
<b>P(30)mod</b>	16.20%	0.39%	1.50%	12.30%

3a) Probabilities of events based on data derived from arrays

3b) Probabilities of main events based on fault data

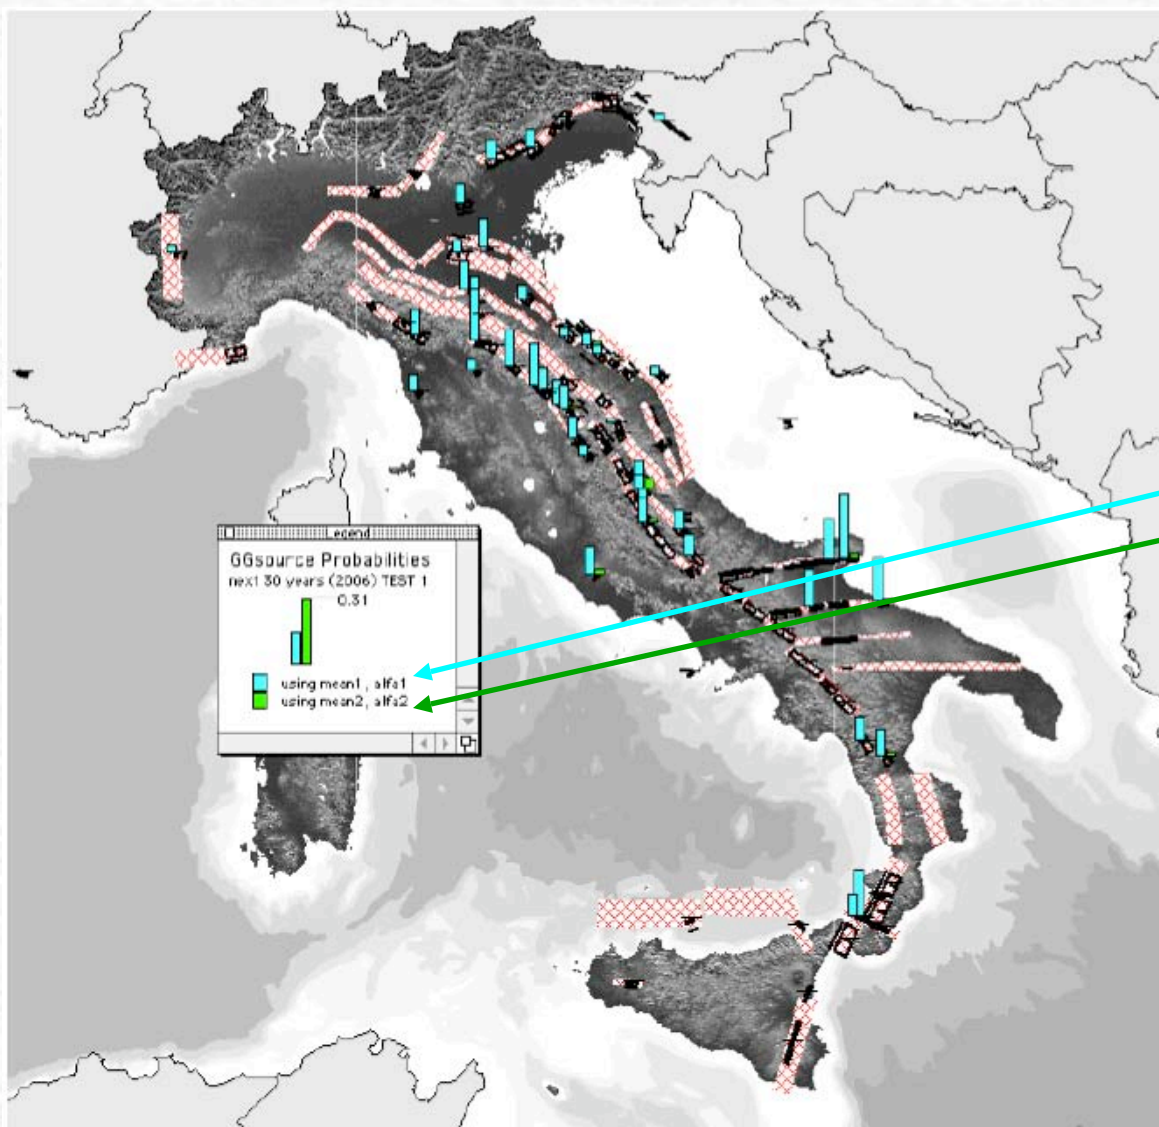

Notable variation (33%)

R<sub>0</sub> = seismicity rate (1/T), if it increases next eq approaches and probability increases;  
 cond = characteristic eq;  
 mod = cond modified by contribution of Coulomb stress

# Probabilities of main events based on fault data

Probability in the next 30 yrs  
on updated DISS faults  
(seismogenic areas are reported only for information)

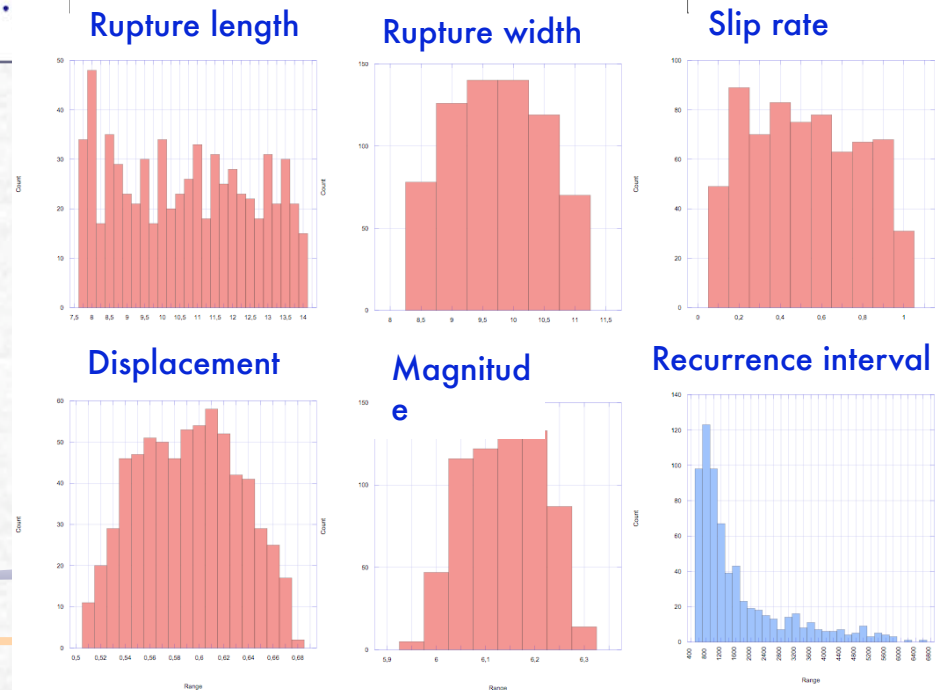

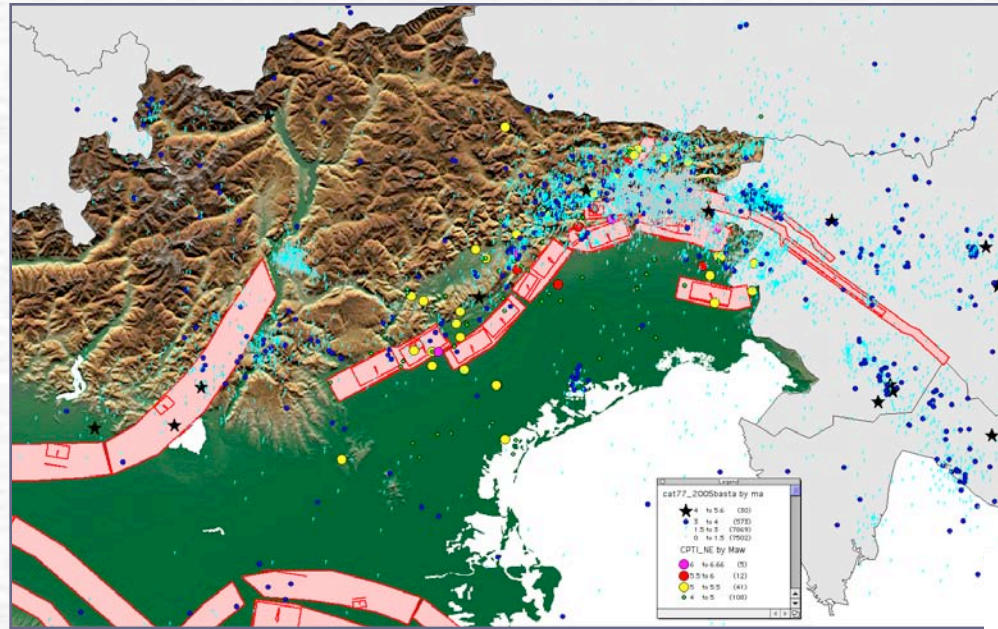

BPT model  
blue = dispersion of the ch eq  
magnitude  
green = slip rate dispersion

Sensitivity to time passed since last eq  
(missing for 1/3 of the faults)

# Statistical parametrization of the SAs

The SAs are occupied by SSs only partly: we can fill the empty space by fictitious SSs defined statistically according to the actual SS distribution in the region

Once we have defined (statistically) the rupture length, width, and slip rate of the fictitious SSs, we can derive all their seismic parameters and assigned them proportionally the total moment rate of the SA.

# Things to be done before the end of the project

- 1) release of the updated version of the DISS database;
- 2) release of the final version of the geodynamic model and an updated set of slip rates derived from it;
- 3) release of the map of the occurrence probability of the characteristic earthquake for the individual SSs (actual or fictitious faults).

Recent advances on assessing  
seismic hazard and earthquake probabilities in Italy  
(yesterday, today, and tomorrow)

This is  
**THE END**

Thanks for your  
attention

## Task 4

### 3b) Probabilities of main events based on fault data

## Slip rate balancing

# Task 4

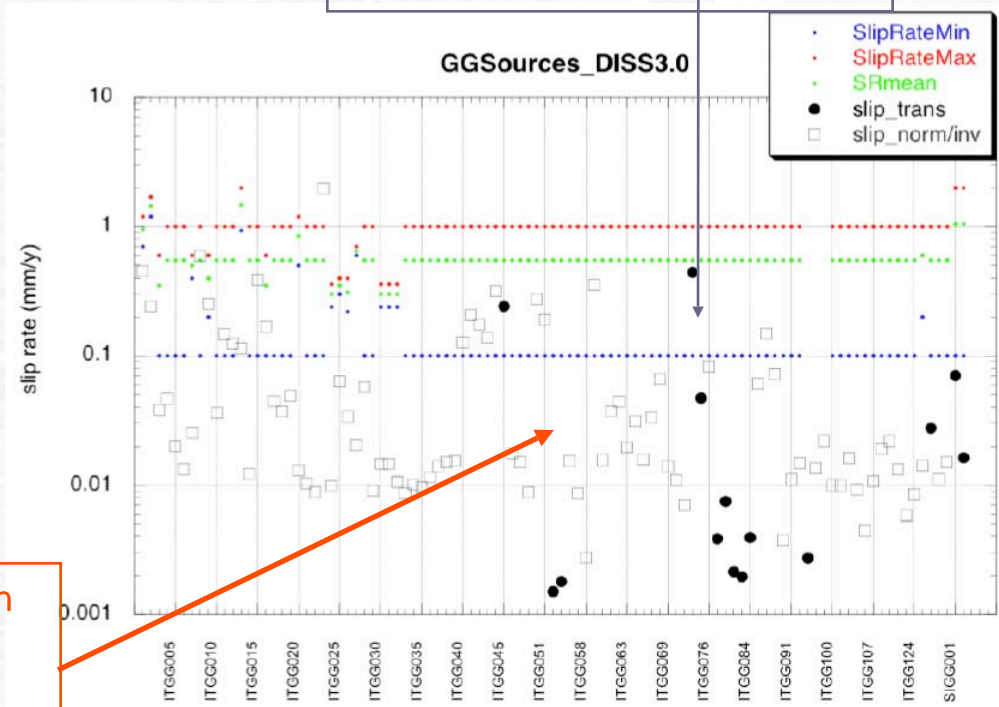

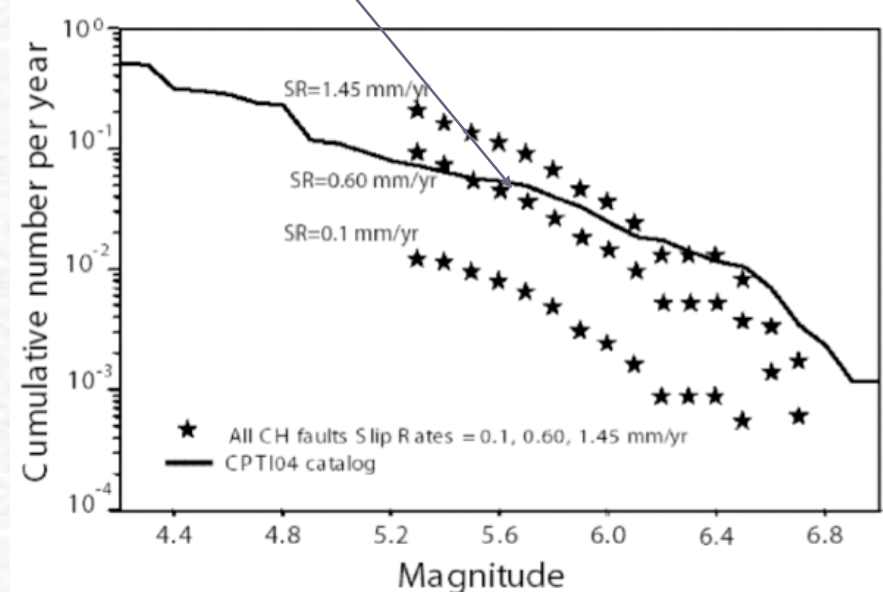

## 3b) Probabilities of main events based on fault data

### Slip rate bilancing

Historical seismicity limits the SR value

Bayes approach for slip rate distribution: posterior = prior \* likelihood  
Likelihood from misfit

Slip rates from geodesy modelling (on ZS9 basis taking into account the fault geometry) and slip rates in DISS

Geodetic slip rates much lower than seismic slip rates
