Foreword

It is our pleasure to present this volume as part of the book series on the Proceedings of the XII International IAEG Congress, Torino 2014.

For the 50th anniversary, the Congress collected contributions relevant to all themes where the IAEG members were involved, both in the research field and in professional activities.

Each volume is related to a specific topic, including:

1. Climate Change and Engineering Geology;
2. Landslide Processes;
3. River Basins, Reservoir Sedimentation and Water Resources;
4. Marine and Coastal Processes;
5. Urban Geology, Sustainable Planning and Landscape Exploitation;
6. Applied Geology for Major Engineering Projects;
7. Education, Professional Ethics and Public Recognition of Engineering Geology;
8. Preservation of Cultural Heritage.

The book series aims at constituting a milestone for our association, and a bridge for the development and challenges of Engineering Geology towards the future.

This ambition stimulated numerous conveners, who committed themselves to collect a large number of contributions from all parts of the world, and to select the best papers through two review stages. To highlight the work done by the conveners, the table of contents of the volumes maintains the structure of the sessions of the Congress.

The lectures delivered by prominent scientists, as well as the contributions of authors, have explored several questions ranging from scientific to economic aspects, from professional applications to ethical issues, which all have a possible impact on society and territory.

This volume testifies the evolution of engineering geology during the last 50 years, and summarizes the recent results. We hope that you will be able to find stimulating contributions, which will support your research or professional activities.

Preface

Landslides and slope stability are one of the leading professional and research fields for engineering geologists. They have been addressed in the IAEG conferences and meetings since the very beginning of the Association. More than 400 contributions related to landslide processes have been submitted to this 12th IAEG congress. They constitute a representative sample of the developments achieved during the last few years and of the challenges our geoscientific community is faced with.

Landslide Mechanisms

Landslides and catastrophic rock and soil failures are due to a variety of mechanisms, some of which are still insufficiently known. This may explain why after more than 35 years, the well-known classification of landslide processes proposed by Varnes in 1978 is still being revisited and updated.

Several sessions in the Congress are devoted to the mechanisms affecting complex geological formations and large slope failures. One of them is focused on the so-called hard soils and soft rocks. Overconsolidated clays and argillaceous soft rocks cause frequent problems in civil works regarding the stability and degradation on exposed surfaces. These materials exhibit a quasi-brittle behavior. Fragility is often associated with loss of cementation of the material and consequently a drop of the shear strength which favors strain localization phenomena and development of progressive failure. The evolution of the movements may include catastrophic acceleration.

Significant research efforts have also been devoted to gain better understanding of the evolution of large slope deformations and to the prediction of their potential to catastrophic failures. Some slope deformations are slow and ductile, moving in a continuous or intermittent manner, others are brittle and after a certain deformation, or as a result of sudden loading (e.g., during an earthquake), they may accelerate, fail, and attain extremely rapid velocities. The failure of large rock masses may involve in-situ rock blocks bounded by a combination of nonsystematic joints and intact rock bridges. The instability process may lead to loss of cohesion, fragmentation of the rock mass, and very rapid flow such as rock avalanching (sturzsstroms).

Techniques for Landslide Characterization and Monitoring

Different instrumentation systems have been developed to monitor landslide behavior, and they are used in many locations around the world. They are often employed in conjunction with surface mapping and subsurface investigations for a detailed characterization of slopes and landslides. Landslide monitoring has several purposes: it provides information about the geometry of the failure, the movement pattern as well as data for the calibration of analytical

and numerical models. The interpretation of the temporal evolution of the different variables is the basis of early warning systems.

The automation of piezometers, inclinometers, extensometers, and distance meters has made possible the monitoring of virtually continuous motion and pore pressure changes. The interpretation of the data recorded has allowed the establishment of consistent relationships between instability triggers and slope deformations. Furthermore, it has highlighted the importance of elements such as cracks and macropores in the hydrological response of landslides.

Many landslides show spatially complex movements. Ground-based equipment such as extensometers or inclinometers are situated at specific locations on a landslide. Such monitoring devices are often costly to install, require access to the site while they yield spatially discontinuous data. The interpretation of the monitoring results requires a proper understanding of the landslide's geomorphological context, and of its different units. Remote sensing techniques are being now increasingly used in landslide investigations, because of their ability to survey large areas and acquire data with high accuracy and high spatial resolution without the accessibility constraints of other equipment and their performance in adverse weather conditions. Two main remote sensing techniques have been intensively tested in the recent years: the terrestrial and aerial laser scanner (LiDAR) and radar interferometry (InSAR), both satellite or ground-based. The laser scanner has multiple applications in slope stability, particularly in rock slopes. It generates high-resolution point clouds of the topographic surface from which one can derive detailed DEMs with highlighted geomorphological features; this can improve the quality of landslide inventories. Detailed DEMs can be used to define discontinuity surfaces and their attributes (i.e., orientation, persistence, spacing) and the deformation pattern of the monitored surfaces allowing the characterization of the instability process. Multitemporal DEMs analysis can also be used to detect morphological and volumetric changes over time.

Advanced InSAR techniques have become a powerful tool for spatio-temporal monitoring ground movements such as subsidence, surface displacements due to landslides or tectonic activity. An additional advantage of InSAR is the existence of a historical database of satellite SAR images (since 1992), enabling retrospective studies.

Other satellite-based sensors are currently available providing information with different spatial, temporal, and spectral resolution. A large number of crucial input data are obtained regarding soil type, vegetation, or land cover; these can be converted into maps through spatial interpolation using environmental correlation with landscape attributes (e.g., geostatistical interpolation methods such as cokriging) that can be easily integrated into GIS for landslide susceptibility and hazard analyses.

Landslide Hazard and Risk Assessment

Risk analysis involves the location, characterization of the landslide (classification, size, velocity, mechanism), and assessment of its travel distance and frequency, which is the hazard analysis; and the consequence analysis that takes into account the presence of the elements at risk, their temporal spatial probability and vulnerability. Risk analysis includes both hazard and consequences analyses. In risk assessment, the results of both analyses are evaluated against value judgments and risk acceptance criteria.

There have been significant advances in regional and local mapping of landslide hazard. The contributions presented to this congress nicely show the recent achievements as well as the shifting of the researchers' interest from landslide susceptibility to landslide hazard assessment and mapping. Furthermore, a parallel evolution has taken place from qualitative to quantitative approaches. The latter have several advantages as they offer more objectivity in the assessment; eliminate misinterpretations and the use of ambiguous terms; yield

reproducible and consistent results; provide a direct input to the cost/benefit analyses. Nowadays, there exist well-founded procedures for the quantitative analysis.

The methods for preparing hazard maps have evolved from the heuristic approaches, to the statistical analyses and data driven methods, and to the deterministic analyses. The capability of the latter has expanded from the stability of individual landslides to spatially distributed models that calculate likelihood of rupture in combination with the return period of the triggers (rain and/or seismicity). The main drawback of these models is that they often oversimplify the geological and geomechanical variables and that should be based on high quality collected data.

The reliability of the hazard maps has improved thanks to high-resolution DEM obtained with remote sensing techniques and the development of data capture techniques. Several researchers have shown that higher resolution DEM on one hand improves significantly the results of slope stability and susceptibility models and on the other hand reduces the errors associated to trajectographic analysis or landslide runout simulations.

The spatial distribution of the hazard may be challenging for long runout landslides for which the probability of failure at the source area may differ significantly from the probability of the landslide reaching a specific area. In this case, calculation of hazard must take into account that: (a) different landslide types may occur with different time frames; (b) a target area may be potentially affected by landslides originating from different source areas; (c) the frequency observed at any target location or section may change with the distance to the landslide source. The practical application of the landslide hazard assessment therefore requires a multiple approach which should take into account the different failure mechanisms, each with different characteristics and causal factors, size, and spatio-temporal probability.

Landslide Prevention and Management

Risk management identifies the measures that may be taken to avoid damages to the society, if required. Different strategies can be considered and they may be synthesized as: risk acceptance, hazard avoidance, hazard reduction, and risk mitigation. Each strategy implements specific measures aiming at either modifying the slope conditions to reduce instability or restrict its development and damaging capability (active measures), or at avoiding the harmful effects of the landslide without interfering with its occurrence (passive measures).

Landslide mitigation measures may include structural measures when they involve any kind of engineering construction or intensive earth work. Stabilization and protection methods are often expensive and may cause irreversible impacts on the mountain ecosystem. However, structural measures cannot always guarantee full protection; and they require careful engineering design, and appropriate maintenance. Among all the options, the avoidance of landslide-threatened areas is the best alternative, and land use planning is a fundamental tool in promoting less expensive and sustainable development. However, the landslide prevention measures, and specifically the implementation of alert systems, have to be considered when the population or infrastructures are directly threatened.

The risk from landslide activity ought to be reducible by implementing early warning systems (EWS). An EWS does not modify the hazard, but does contribute to a reduction in the landslides consequences, in particular the loss of lives and thus the risk. It requires appropriate monitoring, definition of threshold values, short-term prediction of behavior, and then taking action to minimize risk when hazardous events are expected. The scientific and engineering community is knowledgeable about what causes landslides and what reactivates them, however predicting short-term evolution of a slope or a change in landslide activity is still subjected to uncertainties and errors. Without accurate predictions of short-term behavior (based on appropriate monitoring), made without false alarms and with sufficient advance warning to

enable the community at risk to take appropriate action, warning systems cannot be relied upon.

EWS are installed with the aim of making accurate predictions of the behavior of landslides. While some systems operate with triggering thresholds such as the recorded rainfall, others are based on the analysis of the deformation trend and for their interpretation adequate knowledge of material rheology is required. The capturing and interpretation of small-scale prefailure displacements is a fundamental task for landslide prevention. Researchers have shown that different types of landslide may display different patterns of acceleration before failure, and thus that monitoring very small-scale precursory movements offers the prospect of forecasting a slope failure.

Finally, monitored data may be integrated within predictive tools which can involve an empirical and semi-empirical interpretation of deformation field phenomena. This is done using quantitative geological and geomorphological criteria or through the development and implementation of more general and powerful computational models.

Part XXIII Monitoring and Modeling of Landslide Processes

- 253 Real-Time Monitoring and Data Analysis of an Active Landslide in the Three Gorges Reservoir** 1433
Haifeng Huang, Wu Yi, Qinglin Yi, and Shuqiang Lu
- 254 GIS-Based Deterministic Analysis of Deep-Seated Slope Stability in a Complex Geological Setting** 1437
Martin Mergili, Ivan Marchesini, Massimiliano Alvioli, Mauro Rossi, Michele Santangelo, Mauro Cardinali, Francesca Ardizzone, Federica Fiorucci, Barbara Schneider-Muntau, Wolfgang Fellin, and Fausto Guzzetti
- 255 Slope Stability Analyses of the Proposed Reconstituted Slope of the Quarry Heights Drive Landslide, Durban, South Africa** 1441
P. Naidoo, E.D.C. Hingston, and K. Ribbink
- 256 Landslide Modeling Basing on Probability Theory of Renewal Processes** 1447
A.S. Victorov, T.V. Orlov, and O.N. Trapeznikova
- 257 Empirical Verification of Stochastic Theory for Landslide Hazard Forecasting (Seattle Case Study)** 1451
T.V. Orlov and A.S. Victorov
- 258 Map Numerical Modelling of Landslides Using Data from Different Monitoring Systems: The Example of Rosone (Western Alps)** 1455
Davide Notti, Claudia Meisina, Francesco Zucca, Giuseppe Balduzzi, and Alessio Colombo
- 259 Modelling of Landslide Seismicity Using the Smooth Particle Method** 1461
Andreas S. Eisermann and Manfred Joswig
- 260 About the Landslide Hazard Criteria for the Transportation Safety of the 2014 Sochi Olympics** 1469
Postoev German, Kazeev Andrey, and Fedotova Ksenia

Part XXIV Numerical and Analytical Methods for Prediction of Landslide Deformation Evolution

- 261 Mechanical Behavior of Cores of Earth Dams Built with Marls: Analysis of the Influence of Organic and Inorganic Carbonates** 1475
F. Lamas and R. Bravo
- 262 Monitoring of the Shear and Compression Deformation in a Sandy Model Slope Under Artificial Rainfall** 1481
Katsuo Sasahara, Naoki Sakai, and Kazuya Itoh
- 263 Numerical Simulations for the Possible Future Geohazard Events in the Rječina Valley, Croatia** 1485
Chunxiang Wang, Hideaki Marui, Naoki Watanabe, and Gen Furuya

265	Natural Slope Stabilization with Self-Compacting Concrete: Numerical Simulation with the Finite-Element Method	1495
	J.L. Piqueras Sala, J.A. Ramos Martín, R. Mingorance Mingorance, and F. Lamas Fernández	
266	Evaluation on Effect of Landslide Control Based on Hierarchy-Fuzzy Comprehensive Evaluation Method	1501
	Yong Zhang, Sheng-wei Shi, Jun Song, and Ying-jian Cheng	
267	Slope Stability Evaluation of Stiff Fissured Clays and Shales for Different Failure Conditions	1507
	Chrysanthos Steiakakis, Zacharias Agioutantis, and Evangelia Apostolou	
268	The Ivancich Active Landslide Process (Assisi, Central Italy) Analysed via Numerical Modeling Jointly Optimized by DInSAR and Inclinometric Data	1513
	R. Castaldo, P. Tizzani, P. Lollino, F. Calò, F. Ardizzone, M. Manunta, F. Guzzetti, and R. Lanari	
269	3D Stability Analysis of the Portalet Landslide Using Finite Element Method	1519
	Guadalupe Bru, Jose Antonio Fernández-Merodo, Juan Carlos García-Davalillo, Gerardo Herrera, and Jose Fernández	
Part XXV Passive Seismic Methods for Unstable Masses Monitoring		
270	Microseismicity and Acoustic Emission for Landslide Monitoring (North-East Italy)	1527
	Giuliana Zoppè, Giovanni Costa, Neil Dixon, Matthew Peter Spriggs, and Gianluca Marcato	
271	Analysis of Pre-collapse Failure Signals from a Destructive Rockfall by Nanoseismic Monitoring	1531
	Marco Walter, Ulrich Schwaderer, and Manfred Joswig	
272	Seismic Monitoring of a Rockslide: The Torgiovanetto Quarry (Central Apennines, Italy)	1537
	A. Lotti, G. Saccorotti, A. Fiaschi, L. Matassoni, G. Gigli, V. Pazzi, and N. Casagli	
273	SeiSlide: A Matlab® Processing Framework for the Seismological Monitoring of Unstable Geological Masses	1541
	Saccorotti Gilberto, Fiaschi Andrea, Matassoni Luca, and Lotti Alessia	

Part XXVI Prediction Methods for Rainfall Triggered Landslides

- 274 Preliminary Remarks About Rainfall Thresholds for Triggering Debris Flows on the Messina Area** 1547
Luca Falconi, Carmelo Gioè, Simona Malerba, and Claudio Puglisi
- 275 Rainfall Threshold and Landslides in the Post-orogenic Complex of the Esino River Basin, Central Italy** 1553
Eleonora Gioia, Gabriella Speranza, Federica Appiotti, Maurizio Ferretti, and Fausto Marincioni
- 276 Hysteresis Effect on the Deep-Seated Landslide by Rainfall: The Case of the Kualiangzi Landslide, China** 1557
Qiang Xu, Wenhui Li, Hanxiang Liu, Ran Tang, Sijiao Chen, and Xu Sun
- 277 Monitoring and Modelling of Soil–Atmosphere Interaction on a Slope Affected by Shallow Landslides** 1563
Roberto Valentino, Massimiliano Bordoni, Claudia Meisina, Davide Zizioli, Marco Bittelli, and Silvia Chersich
- 278 Long-Term Hydrological Modelling of Pyroclastic Soil Mantled Slopes for Assessing Rainfall Thresholds Triggering Debris Flows: The Case of the Sarno Mountains (Campania—Southern Italy)** 1567
Elisabetta Napolitano, Pantaleone De Vita, Francesco Fusco, Vincenzo Allocca, and Ferdinando Manna
- 279 A Preliminary Study of the Rainfall Threshold and Early Warning System for Landslide in Taiwan** 1571
Lun-Wei Wei, Ching-Fang Lee, Chuen-Ming Huang, Wei-Kai Huang, Hsi-Hung Lin, and Chung-Chi Chi
- 280 Catalogue of Rainfall Events with Shallow Landslides and New Rainfall Thresholds in Italy** 1575
Maria Teresa Brunetti, Silvia Peruccacci, Loredana Antronico, Devis Bartolini, Andrea Maria Deganutti, Stefano Luigi Gariano, Giulio Iovine, Silvia Luciani, Fabio Luino, Massimo Melillo, Michela Rosa Palladino, Mario Parise, Mauro Rossi, Laura Turconi, Carmela Vennari, Giovanna Vessia, Alessia Viero, and Fausto Guzzetti
- 281 Rainfall Intensity-Duration Thresholds for Triggering Shallow Landslides in the Eastern Ligurian Riviera (Italy)** 1581
Roberto Giannecchini, Yuri Galanti, and Michele Barsanti
- 282 Establishing Landslide Susceptibility Along a Coastal Range Highway in Eastern Taiwan** 1585
Ching-Fang Lee, Wei-Kai Huang, Lun-Wei Wei, Ting-Chi Tsao, Yu-Lin Chang, and Shu-Yeong Chi
- 283 Prediction Analysis of Rainfall Induced Landslide in a Samnite Prone Area** 1593
Grelle Gerardo, Revellino Paola, Guerriero Luigi, Soriano Marcella, Diodato Nazzareno, and Guadagno Francesco Maria

284	Landslides Triggered in the Continental Part of Croatia by Extreme Precipitation in 2013	1599
	Sanja Bernat, Snježana Mihalić Arbanas, and Martin Krkač

379	Description and Mechanism of a Landslide in SE Queensland Following Ex-tropical Cyclone Oswald	2119
	Bari I. Thomas and Graham Rose	
380	Analysis of Transient Pore Pressure Distribution and Safety Factor of a Slow Clayey Deep-Seated Landslide by 2D and 3D Models	2123
	Roberto Vassallo, Giuseppe Maria Grimaldi, and Caterina Di Maio	
381	Hydrogeology, Hydrochemistry and Isotopic Investigation to Define the Lateral Hydraulic Boundaries of a Deep Rock Slide (Berceto Landslide: Northern Apennines)	2129
	Manuela Deiana, Federico Cervi, Alessandro Corsini, Antonio Ambanelli, Michela Diena, Luigi Lopardo, Giovanni Truffelli, and Francesco Ronchetti	
382	Influence of Pore Fluid Composition on the Residual Strength of a Clayey Landslide	2133
	Caterina Di Maio, Gianvito Scaringi, and Roberto Vassallo	
383	Hydrochemical Approach of Mechanical Degradation of the Séchilienne Unstable Slope	2137
	C. Bertrand, A. Vallet, and J. Mudry	

384 Hydrogeological Threshold Using Support Vector Machines and Effective Rainfall Applied to a Deep Seated Unstable Slope (Séchilienne, French Alps)	2143
Aurélien Vallet, Davit Varron, Catherine Bertrand, and Jacques Mudry	
385 Geotechnical Investigations in an Old Landslide Situated in Fine-Grained Neogene Sediments (Alkofen, Bavaria, Germany).	2147
Georg Stockinger, Marion Nickmann, and Kurosch Thuro	
386 Steady Lateral Flow in Sloping Soils: Which is the Effect of the Conductivity at Saturation Profile?	2153
Stefano Barontini, Marco Falocchi, and Roberto Ranzi	
387 Estimation of Long-Term Strength of Rock Based on Subcritical Crack Growth	2157
Yoshitaka Nara, Yuma Oe, Sumihiko Murata, Tsuyoshi Ishida, and Katsuhiko Kaneko	
388 Characterization of Laterites for Engineering Geological Applications. . .	2161
R. Nagarajan	
Erratum to: Objective Definition of Rainfall Intensity-Duration Thresholds for Post-fire Flash Floods and Debris Flows in the Area Burned by the Waldo Canyon Fire, Colorado, USA	E1
Dennis M. Staley, Jason W. Kean, and Joseph E. Gartner	
Author Index	2167

The Istituto di Ricerca per la Protezione Idrogeologica (IRPI), of the Italian Consiglio Nazionale delle Ricerche (CNR), designs and executes research, technical and development activities in the vast and variegated field of natural hazards, vulnerability assessment and geo-

risk mitigation. We study all geo-hydrological hazards, including floods, landslides, erosion processes, subsidence, droughts, and hazards in coastal and mountain areas. We investigate the availability and quality of water, the exploitation of geo-resources, and the disposal of wastes. We research the expected impact of climatic and environmental changes on geo-hazards and geo-resources, and we contribute to the design of sustainable adaptation strategies. Our outreach activities contribute to educate and inform on geo-hazards and their consequences in Italy.

We conduct our research and technical activities at various geographical and temporal scales, and in different physiographic and climatic regions, in Italy, in Europe, and in the World. Our scientific objective is the production of new knowledge about potentially dangerous natural phenomena, and their interactions with the natural and the human environment. We develop products, services, technologies and tools for the advanced, timely and accurate detection and monitoring of geo-hazards, for the assessment of geo-risks, and for the design and the implementation of sustainable strategies for risk reduction and adaptation. We are 100 dedicated scientists, technicians and administrative staff operating in five centres located in Perugia (headquarter), Bari, Cosenza, Padova and Torino. Our network of labs and expertizes is a recognized Centre of Competence on geo-hydrological hazards and risks for the Italian Civil Protection Department, an Office of the Prime Minister.
