Abstract

Of late, several biologically active antioxidants from natural products have been investigated by the researchers in order to combat the root cause of carcinogenesis, i.e., oxidative stress. Mangiferin, a therapeutically active C-glucosylated xanthone, is extracted from pulp, peel, seed, bark and leaf of Mangifera indica. These polyphenols of mangiferin exhibit antioxidant properties and tend to decrease the oxygen-free radicals, thereby reducing the DNA damage. Indeed, its capability to modulate several key inflammatory pathways undoubtedly helps in stalling the progression of carcinogenesis. The current review article emphasizes an updated account on the patents published on the chemopreventive action of Mangiferin, apoptosis induction made on various cancer cells, along with proposed antioxidative activities and patent mapping of other important therapeutic properties. Considering it as promising polyphenol, this paper would also summarize the diverse molecular targets of Mangiferin.

Keywords: Chemoprotective, Antioxidants, Anti-inflammatory, Apoptosis, Bioactive, Patent mapping, Multiple molecular targets, Extraction and isolation of polyphenols, Isomangiferin, Homomangiferin,
1. Introduction

Cancer has been affecting mankind since decades. Repeated victims of this most devastating disease are vital organs like lung, liver, breast, colorectum, prostate, oesophagous and stomach. It has been spreading like havoc and is expected to take tens of millions newer patients into the fold by 2020 [1]. The key element significantly aggravating cancer is oxidative stress. Primarily, the inability of the body to detoxify the generated free radicals leads to cancer. A great deal of research has been undertaken across the global laboratories to combat this deadly disease. Even after enormous efforts and dedicated research conducted in this domain, the struggle to beat cancer still seems to be an ongoing process, if not a distant dream. Although various anticancer drugs, incorporated in various delivery systems are continuously being introduced in the market, yet each one is associated with the vital concerns of poor bioavailability, high cost, accompanied with off-target side effects [2]. Antioxidants, in this regard, have caught the clairvoyant eye of researchers for their chemopreventive usage against cancer. Many biologically active antioxidants extracted from diverse flora have been explored and identified by the academicians and industrial researchers. Fundamentally, these tend to scavenge the free radicals by interrupting the oxidative chain reactions [3].

One of the naturally occurring glycosylxanthone that has gained rapid importance recently, in this context is Mangiferin (Mgf). It is a polyphenolic C-glycoside, basically extracted from the leaves, stem barks and fruits of Mango tree, Mangifera indica from Anacardiaceae family. It is a heat-stable molecule with molecular weight less than 500 daltons. It has attracted the attention of the scientists worldwide, as it possesses numerous pharmacological activities other than acting merely as an antioxidant [4]. It is known to be an anti-inflammatory, anti-viral, analgesic, immunomodulatory [5] [6], antidiabetic [7] and many more. Several literature instances have cited and reported the ability of Mgf to inhibit
the cancer cells by inducing apoptosis. It has been observed in various animal models that it could act as a potent antioxidant by reducing free radical species, thereby preventing the potential DNA damage [8]. Currently, Mgf is in advanced preclinical stages and its formulations are set to undergo clinical trials subsequently. The current review article will highlight the patents filed on Mgf emphasizing its role not only as an antioxidant, but also to uncover its other beneficial characteristics, propagating it as a promising futuristic bioactive.

2. Source of Mangiferin: Extraction and Isolation

Owing to its myriad pharmacological activities and easy availability, Mgf has allured the interest of the researchers to develop efficient extraction and isolation methods, which could result in its maximum yield. The prime source of Mgf is mango tree, which is found abundantly in nature [9]. Various ancient scriptures talk about the potential of this plant with high nutritive and medicinal values, associated with variegated families like Anacardiaceae [10], Podalyrieae [11], Hypericoideae [12], etc (Figure 1).

![Figure 1: Existence of Mangiferin in three families.](image)

Mgf can be extracted easily through decoctions and infusions of mango because of its hydrophilic nature. Various methods have been described in literature for the extraction and isolation of Mgf from diverse plant parts of mango. Some of the methods opted are Soxhlet extraction, microwave-assisted extraction, and subcritical
extraction using solvents. However, the pitfalls associated with the use of these traditional techniques are the usage of high amount of solvents for extraction, more time consumption and economically less feasible [13]. To overcome these hiccups, various new techniques like supercritical fluid extraction (SFE) [14] and pressurized liquid extraction (PLE) [15], have been lately opted by researchers to obtain maximal yield in shorter time span. These techniques are preferred, as these processes are fast and environment friendly owing due to usage of green solvents such as carbon dioxide (CO₂), ethanol or water. Fernández-Ponce et al. (2012) reported subcritical water extraction method for the extraction of Mgf from varied plant varieties like Osteen, Kensington, Kent and Ataulfo. The extract showed highly potent in vitro antioxidant activity [13]. However, another scientific group, Kim et al., reported the extraction of Mgf from Mahkota Dewa employing same methodology, but making use of supercritical fluids [16]. Most commonly employed supercritical fluid is supercritical carbon dioxide (scCO₂), as it is documented to be ecologically safe, non-toxic and readily available [17]. The extraction yield from subcritical water method has been found to be quite close to the extraction yield using methanol as the extraction solvent, i.e., 21.7 mg/g [16]. Vrushali and Rathod (2014) described ultrasound three phase partitioning (UTPP) method for the extraction of Mgf from mango leaves. The method indicated the highest yield of 41 mg/g in 25 min vis-à-vis the conventional three-phase partitioning (TPP) that reported a yield of 28 mg/g in 2 h. The latter offers a swift and economical technique for extraction of Mgf [18]. Further, Kulkarni and Rathod in 2015 reported the microwave assisted three phase partitioning extraction (MTPP) method. The results obtained indicated higher yield of Mgf by MTPP (95%) in 5 mins as compared with the conventional technique like Soxhlet extraction which usually requires around 5 h. As per the results obtained, the MTPP method proved to be more proficient and faster for extraction of Mgf [19].

In general, it is reported that the content of Mgf in various parts of Mango tree is approximately found to be 4.4 mg/kg in mango pulp [20], 42 mg/kg in seed kernel [21], 1690 mg/kg in mango peel [22] and most abundant 71.4 g/kg in stem bark [23].
Therefore, the usage of newer techniques holds tremendous promise to provide maximal yield for wider exploration at lab and industrial scales.

3. Structural elucidation and other isoforms

To chemically synthesize Mgf being quite tedious as well as expensive, the best way to obtain it is considered to be via its extraction from various biological sources. Chemically, Mgf is C2-D-glucopyranosyl-1,3,6,7- tetrahydroxyxanthone as shown in Figure 2.

![Figure 2. Structure of Mangiferin](image)

In its chemical structure, C-glucosyl xanthone contains aromatic ring attached to the C-C bond of a glucose moiety, contributing towards its high polarity and water solubility. By and large, Mgf gratify Lipinski’s rules, as for properties like molecular weight less than 500 with log P 2.73, fewer donor *viz.* acceptor groups, i.e., less than 5 and 10 to suffice hydrogen bonding; thus signifying the possible modifications that can be accomplished by the medicinal chemists to alter its physiochemical properties [24]. The presence of catechol ring, free hydroxyl groups, redox active aromatic system due to xanthone moiety, is responsible for the antioxidant activity of Mgf. In addition, it possesses proficient iron-chelating properties, resulting in the prevention of hydroxyl radicals to go in Fenton-type reactions principally responsible for oxidation [9].

The other isomeric forms like isomangiferin and homomangiferin are also present along with Mgf in the mango plant. The co-occurrence of these xanthenes was reported earlier in 1975 by Saleh and El-Ansari. Isomangiferin, mostly present in
Anemarrhena asphodeloides, chemically represented as 4-β-D-glucopyranosyl-1, 3, 6, 7-tetrahydroxy-9H-xanthen-9-one [25] whereas homomangiferin is 1,6,7-trihydroxy-3-methoxy-2-C-β-D-glucopyranosyl-xanthone (Figure 3 a,b).

![Chemical structures of Anemarrhena asphodeloides and homomangiferin](image)

Figure 3. Mangiferin isomeric forms a) Isomangiferin b) Homomangiferin

4. Mechanism of action: As an antioxidant

The antioxidant potential of this xanthone derivative has been well established over the years. As already stated, polyphenols contribute to its free radical scavenging properties by arresting the generated free radicals. The possible responsible mechanistic pathways for the same include, the formation of iron chelates, inhibiting lipoxygenases and scavenging free radicals [26].

Iron is an essential micronutrient that plays a key role in normal cellular physiology. Once the concentration of iron reaches the threshold level, it may result in the generation of catalytic response towards formation of oxyradicals. These free radicals have the ability to disrupt the cellular membrane lipids, nucleic acid chains, carbohydrates and proteins, ultimately impairing the normal cellular functions of body [27]. Mgf, in this regard may reduce the oxidative damage by forming iron chelates. It is well-documented that noranthryriol, a product of Mgf metabolism, exhibits strong iron-chelating property [26]. It was been found that Mgf preserves the integrity of mitochondrial membrane by protecting it from lipid peroxidation.
Gilberto et al. (2007) reported that MgF-Fe(III) complex protects the mitochondrial membrane thiols and glutathiones from oxidation [28]. MgF, by scavenging these reactive species, maintains cellular integrity, thus minimizing the possible damage to erythrocytes [4].

5. Targets for antioxidant properties of MgF: Molecular level
Since ages, polyphenols are known to modulate multiple molecular targets and signalling pathways. MgF, serving as a potent polyphenol, has been shown to affect several biological processes, like inhibition of NF-kB and other transcription factors, reactive oxygen species (ROS), angiogenesis, and apoptosis including mitochondrial bioenergetics [29]. It is reported that the anticancer activity is achieved by cell cycle arrest and direct apoptosis, while its chemoprotective action could be attributed due to its antioxidant and anti-inflammatory activities [30]. These targets enable the chemopreventive actions of MgF by inhibiting the initiation, promotion and metastasis of cancer. Figure 4 and Table 1 highlights the various targets aimed by MgF to curb cancer.

Apart from acting as antioxidant, Mgfpossesses a repertoire of other useful properties. The specific patents in the light of each property have been obtained, and discussed underneath.

1. **Cosmeceuticals:** Gupta et al., 2004 invented a novel ion-pair delivery system in which a charge donor and a charge acceptor composition have been combined synergistically to enhance bioavailability, deposition, functional performance, and consumer aesthetics. This variegated composition was found to be safe and effective
with antioxidants such as non-sulphhydryl donating groups which can enhance skin whitening efficacy [46].

Further, Gupta and Shyam (2006) explored efficacy of hydroxy acids esters as topical compositions serving as beneficial cosmetic and pharmaceutical agents [47]. Another invention by Peter and associates (2013) incorporates topically bioavailable antibacterial agent, Mgf, as antioxidant agent which could improve micro-circulation. The combination cures acne, rosacea, controls excess sebum production and undesirable growth of bacteria or mites, as well as enhanced desquamation of follicular infundibulum cells [48].

Gupta and associates also disclosed an invention, with chirally correct polyene cyclodextrin acetals, and hemiacetals incorporated with antioxidants and anti-inflammatory ketones, that were effective in providing skin clarification and disfigurements, treat acne, and lighten skin darkening resulting from cancer, diabetes, radiation treatments and chemotherapy [49].

2. Arthritic disease: Park Dong-Suk et al., 2009 unravelled an invention comprising of the extract of Mgf mixed herbs with *Lonicera japonica* and *Anemarrhena asphodeloides* showing potent anti-inflammatory activity for safe and effective management of arthritis. The extract contained chlorogenic acid, besides Mgf as the standard component [50].

3. Breast cancer: Wang Ching-chiung in 2011 disclosed an ethyl acetate layer of methanolic extract of *Aquilaria hulls* for preventing cancer. The invention was tested on a group of cancer cell lines like colorectal, gastric, prostate, breast, pancreatic, lung, bladder, colon, cervical and hepatocellular carcinoma [51]. Truog and Buschmann (2014) invented a pharmaceutical composition comprising of phenylbutyric acid derivative, and a chemopreventive agent thereof for use in the prevention of cancer [52].

Also, Halbrook (2013) documented Mgf as a compound and in compositions which could inhibit DNA-dependent protein kinase (DNA-PK). The present DNA-PK inhibitors can be used as diagnostic and therapeutic methods useful in the field of cancer therapy. The reduced exposure to radiation and chemotherapy drugs
improves a patient's prognosis with regard to unwanted adverse side effects that often accompany cancer treatments [53].

4. Colon and Lung cancer: Wang (2012), disclosed that an ethyl acetate layer of methanol extract of *Aquilaria hulls* effectively kills the cancerous cells. The extracts of the same have significant amount of cucurbitacins, which are effective in treating/preventing cancers [51]. Another research conducted by Siegelin and Altieri (2011) revealed a method of enhancing apoptosis in one or more mammalian cells, with at least one mitochondrial-targeted chaperone inhibitor and at least one agent selected from the group consisting of a death receptor agonist, an autophagy inhibitor, and a NF-κB signalling pathway inhibitor, i.e., Mgf [54].

Further, Gerk in 2013, proposed a method for enhancing the bioavailability of orally bioactive phenolic compounds incorporated with one or more inhibitors like presystemic metabolism sulfotransferase (SULTs). Another clinical utilities of Mgf include diabetes, hyperlipidemia, cholestasis, obesity, metabolic syndrome, various cancers, inflammatory diseases, arthritis and anti-aging activities [55]. Meanwhile, surmounting the above inventions, Huang and Wu in 2014 discovered a novel method for treating gastrointestinal spasm in a subject having Crohn's disease or ulcerative colitis. The method comprised of administering an effective amount of water soluble polyphenols consisting of tannins [56].

5. Leukemia: Khwaja and Friedman (1999) invented a delivery system comprising of St. John's Wort materials and unearthing methods for preparing medicinally useful and pharmaceutically acceptable forms which could determine the degree of the given biological activity for each of the marker fractions to provide a bioactivity fingerprint of the representative aliquot [57].

6. Multiple myeloma: Leonard (2011) disclosed a method for treating autoimmune conditions by administering a formulation comprising of mammalian IL-12 antagonist administered during autoimmune conditions, where there is an increase in the levels of IFN-γ or TNF-α. The said formulation has been prescribed particularly during multiple sclerosis, systemic lupus erythematosus, rheumatoid arthritis, autoimmune pulmonary inflammation, Guillain-Barre syndrome,
autoimmune thyroiditis, insulin dependent diabetes mellitus and autoimmune inflammatory eye disease [58].

7. Hepatocellular: Omoigui (2006) invented novel compositions and methods containing Mgf for preventing and treating disorders like atherosclerosis, peripheral vascular disease, coronary artery disease, osteoporosis, type 2 diabetes, dementia and various forms of arthritis. Therapeutically effective dosage forms reported in literature for cancer primarily consist of Mgf in combination with statins, bisphosphonates, cholesterol lowering agents or techniques, interleukin-6 inhibitor, oligonucleotides, tyrosine kinases inhibitors and nuclear factor-κB (NF-κB) inhibitors etc [59].

8. Skin cancer: Huang and Wu (2014) investigated some polyphenols as antioxidants to scavenge unwanted reactive oxygen species which can affect cell-to-cell signalling, receptor sensitivity, inflammatory enzyme activity and even gene regulation in animals [60, 61]. Further, Gupta (2009), reported salient features of water insoluble polycyclic polyisoprenoids conjugated with sugar esters, wherein the alcohol part, and the sugar lactone moiety of said sugar esters are useful for treating multiple skin conditions and ailments [62].

9. Ovarian and Prostate cancer: Dasse (2008) reported that Mgf and various other antioxidants could inhibit the fatty acid amide hydrolase (FAAH) activity which could otherwise lead to increased levels of fatty acid amides to very well manage the ovarian cancer [63]. Supporting the same, Huang (2014) also provided methods incorporating these antioxidants that could treat and provide relief from prostate cancer pain [64].

6. Conclusion and Future Prospects:

Albeit the literature available so far on Mgf is scanty, yet every single piece of information filed, confirms its significant effect on fundamental biological events and processes like stimulating mitochondrial respiration, while suppressing oxidative stress and inflammation. In the light of the above, the current review has attempted to summarize reported patents on chemopreventive and curative potential of Mgf. Its pivotal role to suppress multiple molecular targets in both chronic inflammation and cancer has also been highlighted. Apart from that, it holds great potential to be developed into a nutritional and/or pharmacological therapeutics, as it stimulates mitochondrial respiration, glycolysis and lipolysis. In simple words, we could state that it suppresses gluconeogenesis and lipogenesis. These prominent pharmacological actions have been corroborated by numerous patents documented till date. Also, it is capable of eliciting broad spectrum beneficial biological effects, like analgesic, antipyretic, immunomodulator, antiviral, anthelmintic, antiallergic, antihistaminic, cardioprotective and antiamoebic, by modulating multiple targets [87].

The futuristic research should be focussed on extensive mechanistic investigations into various other unexplored bioactivities, its complete pharmacokinetic exploration to establish ADME patterns, as well as on eagerly awaited pre-clinical and clinical evaluation of pure Mgf, its homologues and isomers, complex extracts or fractions from plants rich in xanthone C-glucosides. An important aspect of research that still needs to be undertaken is to elucidate the issues related to biosynthesis of Mgf and other hydroxyxanthones in plant cells, describing their physiological and endogenous role in plants and the change in content with environmental factors [88]. Detailed investigations and clinical trials, nevertheless, are needed to completely understand its exact mechanism of action against different malignancies and to fully exploit its potential therapeutic effects [89]. As it has low potency and bioavailability, it certainly needs extensive exploration in terms of structure-activity relationship studies. Cheminformatic tools can be used to carry out further studies
establishing the ostensible relationship of structure and activity amongst Mgf and its derivatives. Experimental evidence as well as predictive computational studies, done so far raise a possibility that Mgf could be developed into a multi-target drug. Considering the pertinent information gathered through such patents, Mgf certainly proves to be a promising candidate for futuristic research and development as a part of the multi-potent drug delivery systems. Hence, it seems to be a promising molecule holding ample scope for researchers to work further in its aspects, to unexplored so far.
