Abstract

First order Hamiltonian operators of differential-geometric type were introduced by Dubrovin and Novikov in 1983, and thoroughly investigated by Mokhov. In 2D, they are generated by a pair of compatible flat metrics $g$ and $\tilde{g}$ which satisfy a set of additional constraints coming from the skew-symmetry condition and the Jacobi identity. We demonstrate that these constraints are equivalent to the requirement that $\tilde{g}$ is a linear Killing tensor of $g$ with zero Nijenhuis torsion. This allowed us to obtain a complete classification of $n$-component operators with $n \leq 4$ (for $n = 1, 2$ this was done before). For 2D operators the Darboux theorem does not hold: the operator may not be reducible to constant coefficient form. All interesting (non-constant) examples correspond to the case when the flat pencil $g, \tilde{g}$ is not semisimple, that is, the affinor $\tilde{g}g^{-1}$ has non-trivial Jordan block structure. In the case of a direct sum of Jordan blocks with distinct eigenvalues we obtain a complete classification of Hamiltonian operators for any number of components $n$, revealing a remarkable correspondence with the class of trivial Frobenius manifolds modelled on $H^*(\mathbb{CP}^{n-1})$.

1 Introduction

In 1983 Dubrovin and Novikov introduced Hamiltonian operators of differential-geometric type [8],
\[ P^{ij} = g^{ij}(u) \frac{d}{dx} + b^{ij}_k(u) u^k, \]  
(1.1)
here \( u = (u^1, \ldots, u^n) \) are the dependent variables, and \( i, j, k = 1, \ldots, n \) (we will assume the non-degeneracy condition \( \det g \neq 0 \)). The main observation was that the coefficients of such operators can be interpreted as differential-geometric objects: setting \( b^{ij}_k = -g^{is} \Gamma^j_{sk} \) and considering point transformations of the dependent variables, one can see that the coefficients \( g^{ij} \) and \( \Gamma^j_{sk} \) transform as components of a bivector (contravariant metric), and Christoffel’s symbols of an affine connection, respectively. Imposing the requirement that the corresponding Poisson bracket,
\[ \{F, G\} = \int \frac{\delta F}{\delta u^i} P^{ij} \frac{\delta G}{\delta u^j} \, dx, \]
is skew-symmetric and satisfies the Jacobi identity, one obtains that the bivector \( g^{ij} \) defines a flat metric, and \( \Gamma^j_{sk} \) is the associated Levi-Civita connection. This immediately establishes Darboux’s theorem for such operators: in the flat coordinates of \( g \) the operator \( P \) takes constant coefficient form. Hamiltonian systems of hydrodynamic type are generated by Hamiltonians of the form \( H = \int h(u) \, dx \):
\[ u^i_t = P^{ij} \frac{\delta H}{\delta u^j} = \nabla^i \nabla_j h \, u^j. \]
Such systems appear in a wide range of applications in hydrodynamics, chemical kinetics, the Whitham averaging method, the theory of Frobenius manifolds and so on, see the review papers [7, 22] for further details and references.

Hamiltonian operators of the form (1.1) have subsequently been generalised in a whole variety of different ways (degenerate, non-homogeneous, higher order, multi-dimensional and non-local, see [19] for a review), however, until now very few classification results are available due to the complexity of the problem. In this paper we address the classification of 2D Hamiltonian operators of Dubrovin-Novikov type,
\[ P^{ij} = g^{ij}(u) \frac{d}{dx} + b^{ij}_k(u) u^k + \tilde{g}^{ij}(u) \frac{d}{dy} + \tilde{b}^{ij}_k(u) u^k, \]
(1.2)
that are generated by a pair of flat metrics \( g, \tilde{g} \), see [5, 16, 17]. The operator \( P \) will be called non-degenerate if the tensor \( g + \lambda \tilde{g} \) is non-degenerate for generic values of the parameter \( \lambda \) (without any loss of generality we will assume both \( g \) and \( \tilde{g} \) to
be non-degenerate). Setting $b_{ij}^k = -g^{is} \Gamma^j_{sk}$ and $\tilde{b}_{ij}^k = -\tilde{g}^{is} \tilde{\Gamma}^j_{sk}$, where $\Gamma$ and $\tilde{\Gamma}$ are the Levi-Civita connections of $g$ and $\tilde{g}$, one introduces the obstruction tensor,

$$T^i_{jk} = \tilde{\Gamma}^i_{jk} - \Gamma^i_{jk}.$$ 

It is known that the vanishing of the obstruction tensor is necessary and sufficient for the existence of coordinates where the operator (1.2) takes constant coefficient form [5] (2D Darboux theorem). Our analysis will be based on the following result of Mokhov:

**Theorem 1.** [16] Let $g$ and $\tilde{g}$ be two flat metrics. Formula (1.2) defines a Hamiltonian operator if and only if the obstruction tensor satisfies the relations

$$T^{ijk} = T^{kji},$$

(1.3)

$$T_{\{ijk\}} = 0,$$

(1.4)

$$T^{ij} T^{rs}_{st} = T^{ir} T^{js}_{st},$$

(1.5)

$$\nabla T^{ijk} = 0,$$

(1.6)

$$\tilde{\nabla} T^{ijk} = 0.$$  

(1.7)

Here $T^{ijk} = g^{ir} \tilde{g}^{ks} T^j_{rs}$, brackets $\{ \}$ denote cyclic permutations of the indices $i, j, k$, and $\nabla$, $\tilde{\nabla}$ are covariant differentiations in the Levi-Civita connections of $g$, $\tilde{g}$.

These relations imply that, in the flat coordinates of $g$, the second metric $\tilde{g}$ becomes linear, so that the classification of such operators reduces to the classification of algebras of certain type [5, 16]. This problem was addressed in [16], resulting in a complete description of one- and two-component operators of the form (1.2). Here we adopt a differential-geometric point of view: to proceed with the analysis of the above relations we introduce the affinor (that is, $(1,1)$-tensor) $L = \tilde{g} g^{-1}$ or, using indices, $L^i_j = \tilde{g}^{ik} g_{kj}$. According to [17], $L$ must have zero Nijenhuis torsion (the vanishing of the Nijenhuis torsion is a necessary condition for 1D brackets defined by $g$ and $\tilde{g}$ to be compatible [18, 10]).

In the case when $L$ has simple spectrum, the results of [17] imply the existence of coordinates where the Hamiltonian operator $P$ takes constant coefficient form. It turns out that all interesting (non-constant) examples correspond to the case when $L$ has non-trivial Jordan block structure. The simplest known example of this kind is provided by the two-component operator

$$P = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \frac{d}{dx} + \begin{pmatrix} -2u^1 & u^2 \\ u^2 & 0 \end{pmatrix} \frac{d}{dy} + \begin{pmatrix} -u^1_y & 2u^2_y \\ -u^2_y & 0 \end{pmatrix},$$

(1.8)
which is related to the Lie algebra of vector fields on the plane [5, 16]. It is generated by the flat contravariant metrics

\[ g = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \tilde{g} = \begin{pmatrix} -2u^1 & u^2 \\ u^2 & 0 \end{pmatrix}. \]

One can easily see that, for generic values of \( u^1, u^2 \), the corresponding affinor \( L = \tilde{g}g^{-1} \) is a single \( 2 \times 2 \) Jordan block.

## 2 Summary of the main results

Our first result establishes a link between 2D Hamiltonian operators (1.2) and the theory of Killing tensors:

**Theorem 2.** Let \( g \) and \( \tilde{g} \) be two flat metrics that define the Hamiltonian operator (1.2). The Mokhov conditions (1.3)–(1.7) are equivalent to the following:

1. **Linearity of the bivector** \( \tilde{g}^{ij} \) **in the flat coordinates of** \( g \). Invariantly, this means \( \nabla^2 \tilde{g} = 0 \) where \( \nabla \) denotes covariant differentiation in the Levi-Civita connection of \( g \) (this fact was established earlier in [5, 16]).

2. **The vanishing of the Nijenhuis torsion of the affinor** \( L^i_j = \tilde{g}^{il}g_{lj} \) [17].

3. **The Killing condition for the bivector** \( \tilde{g} \): \( \nabla^i \tilde{g}^{kj} + \nabla^k \tilde{g}^{ij} + \nabla^j \tilde{g}^{ik} = 0 \).

In particular, the flatness of \( g \) and the above three conditions imply flatness of the second metric \( \tilde{g} \).

Thus, the classification of Hamiltonian operators of the form (1.2) is reduced to the classification of linear Killing bivectors with zero Nijenhuis torsion in flat pseudo-Euclidean spaces. A tensorial proof of Theorem 2 is given in Section 3. Using the fact that any Killing bivector in flat space is the sum of symmetrised tensor products of Killing vectors, we obtain a complete classification of 2D Hamiltonian operators with \( n \leq 4 \) components (Section 5).

The Killing condition plays also key role in the proof of the splitting property for Hamiltonian operators, which can be seen as an analogue of the splitting lemma for affinors with zero Nijenhuis torsion proved by Bolsinov and Matveev [1] in the context of projectively equivalent metrics. First of all we recall their result. Let \( M \) be an \( n \)-dimensional manifold, and let \( L \) be an affinor on \( M \) with zero Nijenhuis torsion. Suppose that there exists a frame (not necessarily holonomic) in which \( L \) takes block diagonal form,

\[ L = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}, \quad (2.1) \]
where $\text{Spec}(A) \cap \text{Spec}(B) = \emptyset$. Then there exists a coordinate system $(u, v) = (u^1, \ldots, u^m, v^{m+1}, \ldots, v^n)$ such that $A$ depends on $u$ and $B$ depends on $v$ only, that is, $L$ is a direct sum of two affinors (both with vanishing Nijenhuis torsion).

Adding the Killing condition, in Section 4 we show how to extend this splitting structure to the metrics, namely we prove that, in the same coordinate system, the two metrics $g$ and $\tilde{g}$ also assume block diagonal forms,

$$
g = \begin{pmatrix} g_1(u) & 0 \\ 0 & g_2(v) \end{pmatrix}, \quad \tilde{g} = \begin{pmatrix} \tilde{g}_1(u) & 0 \\ 0 & \tilde{g}_2(v) \end{pmatrix}.
$$

This suggests the definition of reducible operators: given an $m$-component operator $P_1$ with the dependent variables $u^1, \ldots, u^m$, and an $(n-m)$-component operator $P_2$ with the dependent variables $v^{m+1}, \ldots, v^n$, their direct sum is the $n$-component operator $P$ defined by the formula

$$
P = \begin{pmatrix} P_1 & 0 \\ 0 & P_2 \end{pmatrix},
$$

on the combined set of variables $(u^1, \ldots, u^m, v^{m+1}, \ldots, v^n)$. The corresponding metrics $g, \tilde{g}$ will be direct sums of the metrics defining $P_1$ and $P_2$. Operators of this type will be called reducible. Thus, our second result can be formulated as follows:

**The Splitting Lemma.** Let $P$ be a Hamiltonian operator such that the corresponding affinor $L = \tilde{g}g^{-1}$ can be represented in block-diagonal form (2.1) in some (non-holonomic) frame, and let $\text{Spec}(A) \cap \text{Spec}(B) = \emptyset$. Then $P$ decouples into a direct sum of two Hamiltonian operators, with the corresponding affinors $A$ and $B$.

Thus, Hamiltonian operator (1.2) can be represented as a direct sum of irreducible operators $P_\alpha$ (each generated by a pair of flat metrics $g_\alpha, \tilde{g}_\alpha$, defined on a manifold of dimension $n_\alpha$) such that the corresponding affinor $L_\alpha = \tilde{g}_\alpha g_\alpha^{-1}$ either has a unique real eigenvalue of multiplicity $n_\alpha$, or a pair of complex conjugate eigenvalues of the same multiplicity (in the last case $n_\alpha$ must be even).

As a consequence of the splitting lemma we will prove that, if the affinor $L$ is diagonal, then the Hamiltonian operator can be brought to constant coefficient form. This generalises the analogous result of [17] obtained under the additional assumption of simplicity of the spectrum of $L$. In what follows, we will be interested in Hamiltonian operators that are not reducible, and not transformable to constant coefficient form.

Our approach to the classification of Hamiltonian operators in 2D is based on the Killing property. As an illustration, in Section 5 we review the already known two-component case [17], and give a complete classification of three- and four-component Hamiltonian operators. In the three-component case, the main result is as follows.
Theorem 3. Any irreducible non-constant three-component Hamiltonian operator in 2D can be brought (by a transformation of the dependent variables \(u^i\)) to the form \(\pm P\) where \(P\) can have one of the following two canonical forms (in both cases the affinor \(L\) is a single \(3 \times 3\) Jordan block):

1. Jordan block with constant eigenvalue

\[
P = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix} \frac{d}{dx} + \begin{pmatrix} -2u^2 & u^3 & \lambda \\ u^3 & \lambda & 0 \\ \lambda & 0 & 0 \end{pmatrix} \frac{d}{dy} + \begin{pmatrix} -u_y^2 & 2u_y^3 & 0 \\ -u_y^3 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\]

2. Jordan block with non-constant eigenvalue

\[
P = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix} \frac{d}{dx} + \begin{pmatrix} -2u^1 & -\frac{1}{2}u^2 & u^3 \\ -\frac{1}{2}u^2 & u^3 & 0 \\ u^3 & 0 & 0 \end{pmatrix} \frac{d}{dy} + \begin{pmatrix} -u_y^1 & \frac{1}{2}u_y^2 & 2u_y^3 \\ -u_y^2 & \frac{1}{2}u_y^3 & 0 \\ -u_y^3 & 0 & 0 \end{pmatrix}.
\]

Remark. The classification of Hamiltonian operators is performed modulo arbitrary transformations of the dependent variables \(u^i\). Some results can be simplified if we also allow linear transformations of the independent variables \(x, y\). In particular, \(\lambda\)-part of the metric \(\tilde{g}\) in the first canonical form can be set equal to zero via a linear change of \(x\) and \(y\). Note however that linear transformations of \(x, y\) are not well-adapted to the direct sum construction.

Remark. The second canonical form is a three-component version of the \(n\)-component Hamiltonian operator introduced by Mokhov in [16].

In the four-component situation calculations become more complicated, and we get several canonical forms labelled by Segre types of the affinor \(L\), see end of Section 5.

Although our approach works for any number of components \(n\), for \(n > 4\) computations become rather cumbersome. The main difficulty is when the affinor \(L\) consists of several Jordan blocks with the same eigenvalue. In Section 6 we analyse the particular case of a single \(n \times n\) Jordan block:

Theorem 4. Let \(P\) be Hamiltonian operator (1.2) such that the affinor \(L = \tilde{g}g^{-1}\) is a single \(n \times n\) Jordan block with non-constant eigenvalue. Then there exists a coordinate system in which \(g\) and \(\tilde{g}\) can be reduced to the following canonical forms:

\[
g = \pm \begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix}, \quad \tilde{g} = \pm \begin{cases} \mu^{(n;0)} & \text{if } n \neq 1 \mod 3, \\
\mu^{(n;0)} + \kappa_1\mu^{(n;\frac{n-1}{3})} & \text{if } n \equiv 1 \mod 3, n \neq 4, \\
\mu^{(4;0)} + \kappa_1\mu^{(4;1)} + \mu & \text{if } n = 4.
\end{cases}
\]
Here $\kappa_1$ is an arbitrary constant, the symmetric bivector $\mu^{(n;k)}$ is defined as

$$\mu^{(n;k)}_{ij} = [3(i + j) - 2(n + 2 - k)]u^{i+j-1+k},$$

and $\mu$ is the constant symmetric matrix: $\mu^{ij} = \delta^{i,4-j} + \lambda \delta^{i,5-j}, \lambda = \text{const.}$

For the constant eigenvalue case, the analogous statement is given at the end of Section 6. The bivector $\mu^{(n;0)}$ corresponds to the Mokhov operator [16], which is of the single Jordan block type for all $n \neq 4$. Thus, for $n = 3$, the bivector $\mu^{(3;0)}$ gives rise to the second case of Theorem 3. Note that, for $n = 4$, the Mokhov operator has the type of two $2 \times 2$ Jordan blocks: this explains the presence of the term $\mu$ in the formula for $\tilde{g}$ in Theorem 4. This result, combined with the splitting lemma, provides a complete classification of 2D operators of Dubrovin-Novikov type in the case of a direct sum of Jordan blocks with distinct eigenvalues.

In Section 6.2 we show that the case of a single $n \times n$ Jordan block with non-constant eigenvalue gives rise to the trivial non-semisimple Frobenius manifold whose underlying Frobenius algebra corresponds to the cohomology ring of $\mathbb{CP}^{n-1}$.

Finally, in Section 7 we extend our approach to Hamiltonian operators in dimensions higher than two. Recall that the results of [16] imply that, for $d \geq 3$, there exist no non-trivial $d$-dimensional one- or two-component Hamiltonian operators of the form

$$P^{ij} = \sum_{\alpha=1}^{d} \left( g^{ij\alpha}(u) \frac{d}{dx^\alpha} + b^{ij\alpha}_k(u) u^k x^\alpha \right),$$

in other words, any one- or two-component operator of this kind can be transformed to constant coefficient form. We obtain a complete description of three-component operators that are essentially three-dimensional, and cannot be transformed to constant coefficients:

**Theorem 5.** Any non-degenerate three-component Hamiltonian operator in 3D, which is not transformable to constant coefficients, can be brought to one of the two canonical forms:

$$P = \begin{pmatrix} \partial_z & 0 & \partial_x \\ 0 & \partial_x & 0 \\ \partial_x & 0 & 0 \end{pmatrix} + \begin{pmatrix} -2u^2 \partial_y - u^2_y & u^3 \partial_y + 2u^3_y & 0 \\ u^3 \partial_y - u^3_y & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

or

$$P = \begin{pmatrix} 0 & \partial_x & 0 \\ \partial_x & 0 & 0 \\ 0 & 0 & \partial_z \end{pmatrix} + \begin{pmatrix} -2u^1 \partial_y - u^1_y & u^2 \partial_y + 2u^2_y & 0 \\ u^2 \partial_y - u^2_y & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

by a local change of the dependent variables $u^i$, and a linear transformation of the independent variables $x, y, z$ (see Theorem 12 for the analogue of this result if one does not allow linear changes of $x, y, z$).
Note that the second operator is reducible: it is a direct sum of the non-constant two-component operator (1.8), and the operator $\partial_z$. Thus, there exists a unique irreducible three-component operator in 3D.

### 3 Hamiltonian operators and linear Killing tensors with zero Nijenhuis torsion: proof of Theorem 2

In this section we rewrite Mokhov’s conditions (1.3) – (1.7) in the form that is more suitable for our purposes, making link with the theory of Killing tensors.

**Theorem 2.** Let $g$ be a flat metric. Then conditions (1.3) – (1.7) are equivalent to the following:

1. Linearity of $\bar{g}^{jk}$ in the flat coordinates of $g$.
2. Vanishing of the Nijenhuis torsion of the affinor $L_j^i = \bar{g}^{il} g_{lj}$.
3. The Killing condition:
   \[ \nabla^i \bar{g}^{kj} + \nabla^k \bar{g}^{ij} + \nabla^j \bar{g}^{ik} = 0. \] (3.1)

In particular, the flatness of $g$ and the above three conditions imply the flatness of the second metric $\bar{g}$.

**Remark.** The facts that $\bar{g}$ must be linear in the flat coordinates of $g$, and that the Nijenhuis torsion of $L$ must vanish, are well known [5, 16, 17]. They are equivalent to (1.6) and (1.3), respectively. Our contribution here is the Killing property, and the observation that the assumption of flatness of $\bar{g}$ can be dropped.

**Proof of Theorem 2:**

(a). **Condition (1.3) is equivalent to the vanishing of the Nijenhuis torsion of $L$.**

This was proved by Mokhov [18, 20], here we briefly recall the proof. Let $\bar{b}^{ij} = -\bar{g}^{is} \bar{\Gamma}^{dj}_{sk}$ be contravariant Christoffel symbols of the second metric, by definition they satisfy the conditions

\[
\begin{align*}
\partial_k \bar{g}^{ij} &= \bar{b}^{ij}_k + \bar{b}^{ji}_k, \\
\bar{g}^{il} \bar{b}^{jk}_l &= \bar{g}^{jl} \bar{b}^{ik}_l.
\end{align*}
\]

Written in the flat coordinates of $g$, condition (1.3) reads

\[ g^{ij} \bar{b}^{jk}_i = g^{jl} \bar{b}^{ik}_l. \]
Thus, the metrics $\tilde{g}$ and $g$ are almost compatible, and this is known to be equivalent to the vanishing of the Nijenhuis torsion [18].

(b). Condition (1.4) is equivalent to the Killing property. Using (1.3) we can rewrite (1.4) as

$$\sum_{(i,j,k)} [T_{ijk} + T_{kji}] = 0.$$ \hspace{2cm} (1.3)

In the flat coordinates of $g$ we have

$$\sum_{(i,j,k)} [T_{ijk} + T_{kji}] =$$

$$= \tilde{g}^{ks} g^{ir} \tilde{\Gamma}_{rs}^{ij} + \tilde{g}^{is} g^{kr} \tilde{\Gamma}_{rs}^{ij} + \tilde{g}^{js} g^{ir} \tilde{\Gamma}_{rs}^{ik} + \tilde{g}^{js} g^{kr} \tilde{\Gamma}_{rs}^{i} =$$

$$= -[g^{ir} \tilde{\Gamma}_{rs}^{kj} + g^{ks} \tilde{\Gamma}_{rs}^{ij} + g^{jr} \tilde{\Gamma}_{rs}^{ik}] =$$

$$= -[\partial_r \tilde{g}^{kj} + \partial_s \tilde{g}^{ij} + \partial_t \tilde{g}^{ik}] =$$

$$0.$$ \hspace{2cm} (1.4)

In invariant notation, this gives the Killing condition,

$$\nabla^i \tilde{g}^{kj} + \nabla^k \tilde{g}^{ij} + \nabla^j \tilde{g}^{ik} = 0,$$

here $\nabla$ is the Levi-Civita connection of $g$.

(c). Condition (1.6) is equivalent to the linearity of $\tilde{g}$ in the flat coordinates of $g$. In the flat coordinates of $g$, (1.6) implies

$$\partial_r (T_{ijk} + T_{kij}) = \partial_r [g^{it} (\tilde{b}^{kj}_t + \tilde{b}^{ik}_t)] = \partial_r \partial^i \tilde{g}^{jk} = 0.$$ \hspace{2cm} (1.5)

This means that $\tilde{g}$ is linear. Conversely, assuming that $\tilde{g}$ is linear in the flat coordinates of $g$, and using (1.3) and (1.4), we obtain (1.6):

$$0 = \partial_r (T_{ijk} + T_{kij}) = \partial_r (T_{ijk} + T_{jki}) = -\partial_r T^{kij}.$$ \hspace{2cm} (1.6)

(d). Conditions (1.5) and (1.6) are equivalent to the flatness of $\tilde{g}$.

Condition (1.6) means that, in the flat coordinates of $g$, the contravariant Christoffel symbols $\tilde{b}^{ij}_k$ are constant. This follows from the identity

$$-\partial_r T^{kij} = \partial_r (g^{km} \tilde{b}^{ij}_m) = g^{km} \partial_r \tilde{b}^{ij}_m = 0.$$

Similarly, condition (1.7) means that, in the flat coordinates of $\tilde{g}$, the contravariant Christoffel symbols $b^{ij}_k$ are constant. Written in the flat coordinates of $g$, condition (1.5) reads

$$\tilde{g}^{sq} g^{ip} \tilde{\Gamma}_{pq}^{ij} \tilde{\Gamma}_{rs}^{tr} = \tilde{g}^{sq} g^{ip} \tilde{\Gamma}_{pq}^{ij} \tilde{\Gamma}_{rs}^{tr},$$
which is equivalent to
\[ \tilde{b}_p^j b_s^r - \tilde{b}_p^s b_s^j = 0. \]

Due to (1.6), the vanishing of the curvature of \( \tilde{\nabla} \), written in the flat coordinates of \( g \), reads
\[
g^{is} \left( \partial_s \tilde{b}_p^r - \partial_p \tilde{b}_s^r \right) - \tilde{b}_s^i \tilde{b}_p^s + \tilde{b}_s^i \tilde{b}_p^s = -\tilde{b}_s^i \tilde{b}_p^s + \tilde{b}_s^i \tilde{b}_p^s = 0.
\]

(e). Condition (1.7) can be dropped.

Recall that, in the flat coordinates of \( g \), we have \( T_{lkj} = -g^{lm} \tilde{b}_{ml}^k \) and \( T_{ij} = \tilde{\Gamma}_{ij}^k = \tilde{T}_{ij}^k \) (by the symmetry of \( \tilde{\nabla} \)). Straightforward computation gives
\[
\tilde{\nabla}_r T_{ijk} = -(T_{rl} T_{lkj} + T_{lk} T_{rij} + T_{ril} T_{ijl}).
\]

Using conditions (1.3), (1.4) and (1.5) we obtain
\[
\tilde{\nabla}_r T_{ijk} = -T_{rl} (-T_{ijl} + T_{ijl}),
\]
where the last term vanishes by (1.3).

(f). The flatness of \( \tilde{g} \) follows from the flatness of \( g \), linearity of \( \tilde{g} \), the Killing condition, and the vanishing of the Nijenhuis torsion.

Since \( \tilde{b}_{jk}^i \) are constant in the flat coordinates of \( g \) from the condition
\[
\partial_k \tilde{g}^{ij} = \tilde{b}_{kj}^i + \tilde{b}_{jk}^i,
\]
it follows immediately
\[
\tilde{g}^{ij} = (\tilde{b}_{li}^j + \tilde{b}_{lj}^i) u^l + g^{ij}_0 \tag{3.2}
\]
Thus in flat coordinates of \( g \) the condition \( g^{il} \tilde{b}_{lk}^j = \tilde{g}^{jli} \tilde{b}_{lk}^j \) implies
\[
(\tilde{b}_{lk}^s + \tilde{b}_{ls}^k) \tilde{b}_{kp}^s = (\tilde{b}_{ls}^s + \tilde{b}_{sl}^s) \tilde{b}_{kp}^s. \tag{3.3}
\]

Moreover, using (1.3) for the underlined terms we can rewrite the Killing condition
\[
g^{is} (\tilde{b}_{sk}^j + \tilde{b}_{sk}^j) + g^{ks} (\tilde{b}_{sj}^i + \tilde{b}_{sj}^i) + g^{js} (\tilde{b}_{sj}^k + \tilde{b}_{sj}^k) = 0.
\]
in the following form
\[
\tilde{b}_{sj}^j g^{sk} + (\tilde{b}_{sk}^j + \tilde{b}_{sk}^j) g^{sj} = 0 \tag{3.4}
\]
Taking into account the above condition (3.4), the equation (3.3) becomes
\[
g_{mr} \left( g^{sj} \tilde{b}_{lj}^k \tilde{b}_{sp}^j - g^{sj} \tilde{b}_{lp}^k \tilde{b}_{sj}^j \right) = 0.
\]

Using (1.3) for the underlined terms, we finally get
\[
g_{mr} g^{qs} (\tilde{b}_{lj}^p \tilde{b}_{sp}^r - \tilde{b}_{lp}^r \tilde{b}_{sj}^j) = 0.
\]
Remark. Using Mokhov’s conditions it is easy to prove that \( g \) and the homogeneous linear part of \( \tilde{g} \) define an exact flat pencil of metrics. More precisely, we have
\[
\mathcal{L}_X g^{ij} = g_1^{ij},
\]
\[
\mathcal{L}_X g_1^{ij} = 0,
\]
where \( g_1^{ij} = (\tilde{b}_i^j + \tilde{b}_j^i)u^l \) and \( X^i = -g_1^{is}g_{sl}u^l \). Moreover, \( X \) is constant in flat coordinates of \( g_1 \) (\( \nabla_1 X = 0 \)). Exactness is one of the main properties of flat pencils of metrics related to Frobenius manifolds. In this case \( X \) is the vector field defining the unit of the multiplicative structure. This observation suggests that flat pencil of metrics defining 2D Hamiltonian operators might be related to Frobenius manifolds. We will discuss this point in Section 6 in the case of Mokhov’s operator.

Remark. In what follows we will need an alternative form of the Killing condition, namely
\[
g^{is}\partial_s\tilde{g}^{kj} + g^{ks}\partial_s\tilde{g}^{ij} + g^{js}\partial_s\tilde{g}^{ik} - \tilde{g}^{is}\partial_s g^{kj} - \tilde{g}^{ks}\partial_s g^{ij} - \tilde{g}^{js}\partial_s g^{ik} = 0. \tag{3.5}
\]
This can be obtained as follows. Computing covariant derivative of \( \tilde{g}^{ij} \) we get
\[
g^{ks}\nabla_s\tilde{g}^{ij} = g^{ks}\partial_s\tilde{g}^{ij} - \tilde{b}_m^{ki}\tilde{g}^{mj} - \tilde{b}_m^{kj}\tilde{g}^{im}. \tag{3.6}
\]
Using \( \partial_s g^{ij} = b^{ij}_s + b^{ji}_s \) and substituting (3.6) into the Killing conditions, one arrives at (3.5).

4 The splitting lemma

One of the conditions which follows from the Hamiltonian property is the vanishing of the Nijenhuis torsion of the affinor \( L = \tilde{g}g^{-1} \). In the hypothesis that the spectrum of \( L \) can be decoupled into two subsets with empty intersection, Bolsinov and Matveev established the following splitting property:

Lemma 1 (Splitting Lemma, [2]). Let \( L \) be an affinor with zero Nijenhuis torsion on a manifold \( M \), \( \dim M = n \). Suppose there exists a (non-holonomic) frame in which \( L \) takes block diagonal form,
\[
L = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix},
\]
where \( \text{Spec}(A) \cap \text{Spec}(B) = \emptyset \). Then there exists a local coordinate system \((u^1, ..., u^m, v^{m+1}, ..., v^n)\) such that
\[
L = \begin{pmatrix} A(u) & 0 \\ 0 & B(v) \end{pmatrix}.
\]
Using the Killing condition, one can extend the splitting structure to the metrics. First of all we recall the well-known fact from linear algebra: in the hypothesis of the above lemma, if \( g \) and \( \tilde{g} \) are two non-degenerate symmetric bivectors related by the affinor \( L \), that is \( \tilde{g}^{ij} = L^j_k g^{ki} \), then \( g \) and \( \tilde{g} \) assume the form

\[
\begin{align*}
g &= \begin{pmatrix} \sigma & 0 \\ 0 & \eta \end{pmatrix}, \\
\tilde{g} &= \begin{pmatrix} \tilde{\sigma} & 0 \\ 0 & \tilde{\eta} \end{pmatrix},
\end{align*}
\]

(4.1)

(see [2] for applications of this result to the theory of projectively equivalent metrics).

**Lemma 2.** In the hypothesis of Lemma 1, let \( g \) and \( \tilde{g} \) be two non-degenerate symmetric bivectors (4.1) such that \( \tilde{g}^{ij} = L^j_k g^{ki} \). If the Killing condition (3.1) holds, then \( \sigma, \tilde{\sigma} \) must depend only on \( u = (u^1, \ldots, u^m) \), and \( \eta, \tilde{\eta} \) must depend only on \( v = (v^{m+1}, \ldots, v^n) \).

**Proof:**

By Lemma 1, \( A = A(u) \) is an \( m \times m \) matrix, and \( B = B(v) \) is an \( (n - m) \times (n - m) \) matrix. Let \( I = \{1, \ldots, m\} \) and \( J = \{m+1, \ldots, n\} \). We know that if \( i \in I \) and \( j \in J \), then \( g^{ij} = 0 \). Then, for \( i \in I \) and \( j, k \in J \), condition (3.5) leads to

\[
g^i_s \partial_s \tilde{g}^{kj} - \tilde{g}^i_s \partial_s g^{kj} = 0,
\]

in particular,

\[
\sigma^{is} \partial_s \tilde{\eta}^{kj} - \tilde{\sigma}^{is} \partial_s \eta^{kj} = 0.
\]

Multiplying by the inverse matrix \( \sigma_{li} \) we obtain

\[
\partial_l (B^k_p \eta^{pj}) - A^s_l \partial_s \eta^{kj} = 0,
\]

as \( \tilde{\sigma}^{si} \sigma_{il} = A^s_l \). Since \( l \in I \) and the elements of \( B \) depend on \( v \) only, our relation becomes

\[
B^k_p \partial_l \eta^{pj} - A^s_l \partial_s \eta^{kj} = 0.
\]

Fixing \( j \), let \( C^k_l := \partial_l \eta^{kj} \), then we get \( B^k_p C^p_l = C^k_l A^s_l \), that is

\[
BC = CA.
\]

As \( \text{Spec}(A) \cap \text{Spec}(B) = \emptyset \), it follows that \( C \equiv 0 \). Thus

\[
\partial_i \eta^{jk} = 0, \quad \forall \ i \in I, \ \forall \ j, k \in J.
\]

If we now take \( i \in J \) and \( j, k \in I \), following the same method we get

\[
\partial_i \sigma^{jk} = 0, \quad \forall \ i \in J, \ \forall \ j, k \in I.
\]
This establishes the Splitting Lemma formulated in Section 2. It allows us to focus on affinors with one single eigenvalue, otherwise we can split them and consider each block separately.

As a simple application of the splitting lemma we can establish Darboux’s theorem for Hamiltonian operators whose affinor $L$ is diagonal (has no non-trivial Jordan blocks: note that we allow coinciding eigenvalues). It is based on the following result:

**Proposition 1.** Let $L$ be a diagonal affinor, $g$ be a flat contravariant metric, and $\tilde{g} = Lg$. Suppose that the Nijenhuis torsion of $L$ vanishes, and the Killing condition holds. Then there exists a coordinate system where $L$ and $g$ take constant coefficient form.

**Proof:**

Since the Nijenhuis torsion of $L$ vanishes, using the splitting lemma we can bring $L$ to block diagonal form,

$$L = \begin{pmatrix} L_1 & & \\ & L_2 & \\ & & \ddots \end{pmatrix}.$$ 

Here each $L_i$ is a scalar operator with the same eigenvalue,

$$L_i = \begin{pmatrix} \lambda^i \\ & \ddots \\ & & \lambda^i \end{pmatrix},$$

$\lambda^i \neq \lambda^j$ for $i \neq j$, and $\lambda^i$ depends on coordinates of its own block only. By the splitting lemma for metrics, we have

$$g = \begin{pmatrix} g_{\lambda^1} \\ & \ddots \\ & & g_{\lambda^k} \end{pmatrix}, \quad \tilde{g} = \begin{pmatrix} \lambda^1 g_{\lambda^1} \\ & \ddots \\ & & \lambda^k g_{\lambda^k} \end{pmatrix},$$

where $g_{\lambda^i}$ depends on coordinates of its own block only. Thus we can consider each block separately. For instance, suppose $L_1$ is an $m \times m$ scalar operator with the eigenvalue $\lambda_1$. Let us set $\lambda = \lambda^1$ and $h = g_{\lambda^1}$. We know that $\lambda$ and $h$ depend on $u^1, \ldots, u^m$ only, and no other block depends on these coordinates. Condition (3.5) leads to

$$h^{kj} h^{is} \partial_s \lambda + h^{ij} h^{ks} \partial_s \lambda + h^{ik} h^{js} \partial_s \lambda = 0.$$
Since $h$ is non-degenerate, contracting with $h_{qi}h_{pj}$ we get
\[\delta^k_p\partial_q\lambda + h_{pq}h^{ks}\partial_s\lambda + \delta^k_q\partial_p\lambda = 0.\]
Setting $q = k$ and summing over $k$ we obtain
\[\partial_p\lambda + h_{pk}h^{ks}\partial_s\lambda + m\partial_p\lambda = 0 \quad \Rightarrow \quad (m + 2)\partial_p\lambda = 0.\]
Thus $\lambda$ must be constant. Since $g$ is flat, we can find a change of coordinates which brings $h$ to constant form. As $L_1$ is a constant scalar operator, it retains its form in any coordinate system. Similarly $\lambda^i$ and $g_{\lambda^i}$ can be reduced to constant form. \(\blacksquare\)

This leads to the following

**Theorem 6.** Consider a non-degenerate Hamiltonian operator (1.2) such that the affinor $L^i_j := \tilde{g}^{ik}g_{kj}$ has (pointwise) diagonal Jordan normal form. Then this operator can be reduced to constant coefficient form by a local change of coordinates.

This extends the analogous result of Mokhov [17] obtained under the additional assumption of simplicity of the spectrum of $L$.

Suppose that $g$ has Euclidean signature (or, more generally, there exists a non-degenerate Euclidean combination of the form $\lambda g + \mu \tilde{g}$). Then the affinor $L$ can be brought to diagonal form. By Theorem 6 we have

**Corollary.** If one of the contravariant metrics that define a 2D Hamiltonian operator is Euclidean, then the operator can be reduced to constant coefficient form.

This shows that the most interesting case is when each representative of the pencil $\lambda g + \mu \tilde{g}$ is essentially pseudo-Euclidean, and the affinor $L$ has non-trivial Jordan block structure.

## 5 Classification results

In this section we classify Hamiltonian operators of type (1.2) with the number of components $n \leq 4$. This will be done up to arbitrary transformations of the dependent variables $u^i$. Our approach is based on the following two fundamental facts:

1. Any Killing bivector in flat space is the sum of symmetrized tensor products of Killing vectors;
2. A pair of symmetric bivectors can be brought to the Segre normal form.
We recall that the first metric \( g \) can always be reduced to constant form, and the second one must be linear, that is
\[
\tilde{g} = c^{ij}_k u^k + \tilde{g}^{ij},
\]  
(5.1)

here \( g \) and \( g_0 \) are constant symmetric matrices, and \( c^{ij}_k \) are constant coefficients. Taking 'generic' values \( u_0^k \) of the variables \( u^k \) and applying the shift of variables,
\[
u^k \rightarrow u_0^k + v^k,
\]
we obtain the transformed metric,
\[
\tilde{g} = c^{ij}_k v^k + \tilde{g}^{ij}.
\]  
(5.2)

The genericity of \( u_0^k \) allows us to assume that the Segre type of the pair \((g, \tilde{g})\) is the same as that of \((g, \tilde{g}_0)\). Recall that the Segre type of a pair of symmetric forms can be read off the Jordan normal form of the corresponding affinor \( L \), see below. Bringing \( g \) and \( \tilde{g}_0 \) to the Segre normal form leads to a considerable simplification of calculations. Furthermore, the splitting lemma allows us to consider irreducible cases only, where the affinor \( L \) either has one real eigenvalue, or two complex conjugate eigenvalues.

The theory of normal forms of pairs of symmetric bilinear forms is based on the following result, see e.g. [15]:

**Theorem 7.** Suppose \( L \) is a \( g \)-selfadjoint operator on a real vector space \( V \). There exist a canonical basis \( e_1, \ldots, e_n \in V \) in which \( L \) and \( g \) can be simultaneously reduced to the following block diagonal canonical forms:

\[
L_{can} = \begin{pmatrix} L_1 & & \\ & L_2 & \\\\ & & \ddots \\ & & & L_s \end{pmatrix}, \quad g_{can} = \begin{pmatrix} g_1 & & \\ & g_2 & \\\\ & & \ddots \\ & & & g_s \end{pmatrix},
\]

where

\[
g_j = \pm \begin{pmatrix} 1 & & \\ & 1 & \\\\ & & \ddots \\ & & & 1 \end{pmatrix},
\]

and

\[
L_j = \begin{pmatrix} \lambda^j & 1 & & \\ & \lambda^j & & \\\\ & & \ddots & \\ & & & \lambda^j \end{pmatrix},
\]
in the case of real eigenvalues $\lambda^j \in \mathbb{R}$ (real Jordan block), or

$$L_j = \begin{pmatrix}
a & b & 1 & 0 \\
-b & a & 0 & 1 \\
a & b & \ddots & \ddots \\
\vdots & \ddots & 1 & 0 \\
-b & a & 0 & 1 \\
0 & 0 & a & b \\
0 & 0 & -b & a
\end{pmatrix},$$

in the case of complex conjugate eigenvalues $\lambda^{1,2}_j = a \pm ib$ (complex Jordan block). It is assumed that for each $j$ the blocks $g_j$ and $L_j$ are of the same size.

Remark. Let us briefly comment on what we mean by Segre type. Suppose $n = 4$ and let us consider the affinor $L = \tilde{g}g^{-1}$. In the case of two complex conjugate eigenvalues $\nu + i\lambda$ and $\nu - i\lambda$, the canonical form of $L$ reads

$$\begin{pmatrix}
\nu & -\lambda & 1 & 0 \\
\lambda & \nu & 0 & 1 \\
0 & 0 & \nu & -\lambda \\
0 & 0 & \lambda & \nu
\end{pmatrix}.$$ 

In the case of a single real eigenvalue we have the following four canonical forms:

$$\begin{pmatrix}
\lambda & 1 & 0 & 0 \\
0 & \lambda & 1 & 0 \\
0 & 0 & \lambda & 1 \\
0 & 0 & 0 & \lambda
\end{pmatrix}, \quad \begin{pmatrix}
\lambda & 1 & 0 & 0 \\
0 & \lambda & 1 & 0 \\
0 & 0 & \lambda & 0 \\
0 & 0 & 0 & \lambda
\end{pmatrix}, \quad \begin{pmatrix}
\lambda & 1 & 0 & 0 \\
0 & \lambda & 0 & 0 \\
0 & 0 & \lambda & 1 \\
0 & 0 & 0 & \lambda
\end{pmatrix}, \quad \begin{pmatrix}
\lambda & 1 & 0 & 0 \\
0 & \lambda & 0 & 0 \\
0 & 0 & \lambda & 0 \\
0 & 0 & 0 & \lambda
\end{pmatrix}.$$

Segre type indicates the number and sizes of Jordan blocks with the same eigenvalue $\lambda$.

5.1 One-component case

It was shown in [8, 16] that any one-component operator can be reduced to constant coefficient form, $P = \lambda \partial_x + \mu \partial_y$, here $\lambda$ and $\mu$ are arbitrary constants.

5.2 Two-component case

The two-component situation is also understood completely [5, 16]: we have only one non-constant Hamiltonian operator (1.8), the corresponding affinor $L$ is a sin-
gle Jordan block with non-constant eigenvalue:

\[ P = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \frac{d}{dx} + \begin{pmatrix} -2u^1 & u^2 \\ u^2 & 0 \end{pmatrix} \frac{d}{dy} + \begin{pmatrix} -u_y^1 & 2u_y^2 \\ -u_y^2 & 0 \end{pmatrix} \].

Let us give an alternative proof of this result based on the Killing condition. First we reduce \( g \) to flat coordinates,

\[ g = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} , \]

recall that \( g \) must be Lorentzian. Since \( \tilde{g} \) is a Killing tensor of \( g \), it is a quadratic expression in the isometries of \( g \), \( u^1 \partial_{u^1} - u^2 \partial_{u^2}, \partial_{u^1}, \partial_{u^2} \). Since \( \tilde{g} \) is linear, the first isometry can only enter linearly, so that

\[ \tilde{g} = (u^1 \partial_{u^1} - u^2 \partial_{u^2})(\alpha \partial_{u^1} + \beta \partial_{u^2}) + \gamma \partial_{u^1}^2 + 2\delta \partial_{u^1} \partial_{u^2} + \epsilon \partial_{u^2}^2, \]

here \( \alpha, \beta, \gamma, \delta, \epsilon \) are arbitrary constants. The vanishing of the Nijenhuis torsion of the corresponding affinor \( L \) gives

\[ (\alpha u^1 + \gamma)\beta = 0, \quad (\beta u^2 - \epsilon)\alpha = 0. \]

Without any loss of generality one can take \( \beta = 0 \). In this case \( \alpha \) must be nonzero, otherwise \( \tilde{g} \) will have constant coefficients. Then \( \epsilon = 0 \), and modulo translations of \( u^1, u^2 \) we arrive at the required expression (1.8).

### 5.3 Three-component case

Our main result can be summarised as follows.

**Theorem 3.** Any irreducible non-constant three-component Hamiltonian operator in 2D can be brought (by a transformation of the dependent variables \( u^i \)) to the form \( \pm P \) where \( P \) can have one of the following two canonical forms (in both cases the affinor \( L \) is a single 3 \( \times \) 3 Jordan block):

1. **Jordan block with constant eigenvalue**

\[ P = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix} \frac{d}{dx} + \begin{pmatrix} -2u^2 & u^3 & \lambda \\ u^3 & \lambda & 0 \\ \lambda & 0 & 0 \end{pmatrix} \frac{d}{dy} + \begin{pmatrix} -u_y^2 & 2u_y^3 & 0 \\ -u_y^3 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} , \]

2. **Jordan block with non-constant eigenvalue**

\[ P = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix} \frac{d}{dx} + \begin{pmatrix} -2u^1 & -\frac{1}{2}u^2 & u^3 \\ -\frac{1}{2}u^2 & u^3 & 0 \\ u^3 & 0 & 0 \end{pmatrix} \frac{d}{dy} + \begin{pmatrix} -u_y^1 & \frac{1}{2}u_y^2 & 2u_y^3 \\ -u_y^2 & \frac{1}{2}u_y^3 & 0 \\ -u_y^3 & 0 & 0 \end{pmatrix} . \]
Proof:

Since the complex conjugate case cannot occur (it requires an even number of components), we only need to consider the cases where the affinor $L$ has one triple eigenvalue, and has Segre type $[3]$ or $[2, 1]$. Since the case $[2, 1]$ gives no non-constant examples, we will concentrate on Segre type $[3]$. Then there exists a coordinate system where $g$ and $\tilde{g}_0$ take the form

\[
g^{ij} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad \tilde{g}_0^{ij} = \begin{pmatrix} 0 & 1 & \lambda \\ 1 & \lambda & 0 \\ \lambda & 0 & 0 \end{pmatrix}.
\]

The general solution of Mokhov's conditions is given by the two-parameter family $\tilde{g} = \kappa_1 \tilde{g}_1 + \kappa_2 \tilde{g}_2 + \tilde{g}_0$, where $\kappa_i$ are arbitrary constants, and the bivectors $\tilde{g}_i$ are as follows:

\[
\tilde{g}_1 = \begin{pmatrix} -2u^1 & -\frac{1}{2}u^2 & u^3 \\ -\frac{1}{2}u^2 & u^3 & 0 \\ u^3 & 0 & 0 \end{pmatrix}, \quad \tilde{g}_2 = \begin{pmatrix} -2u^2 & u^3 & 0 \\ u^3 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\]

In the non-constant eigenvalue case, $\kappa_1 \neq 0$, using the following transformations that preserve both $g$ and $\tilde{g}_0$,$$
\begin{align*}
u^1 &\to \frac{1}{\kappa_1} u^1 + \frac{2\kappa_2}{\kappa_1^2} u^2 - \frac{2\kappa_2^2}{\kappa_1^3} u^3 - \frac{2\kappa_2}{\kappa_1^3}, \\
u^2 &\to u^2 - \frac{2\kappa_2}{\kappa_1} u^3 + \frac{2\kappa_1 - 2}{\kappa_1}, \\
u^3 &\to \kappa_1 u^3,
\end{align*}
we can reduce the above family to $\tilde{g} = \tilde{g}_1 + \tilde{g}_0$ (that is, we can set $\kappa_1 = 1$, $\kappa_2 = 0$). After that we can eliminate $\tilde{g}_0$ by appropriate translations of $u^2$ and $u^3$, arriving at the final answer $\tilde{g} = \tilde{g}_1$. Similarly, in the constant eigenvalue case, $\kappa_1 = 0$, we can set $\kappa_2 = 1$, and use an appropriate translation of $u^3$ to arrive at the normal form above.

5.4 Four-component case

The four-component situation is more complicated since we have more Segre types. In this section we present the results of classification of four-component Hamiltonian operators of the form (1.2) with one real eigenvalue, as well as with two complex conjugate eigenvalues (the latter turn out to be complexifications of the $2 \times 2$ operator (1.8)). We will only give canonical forms for the contravariant metrics $g, \tilde{g}$: the symbols $\tilde{b}^{ij}_k$ of the second metric can be computed directly. We skip the details of calculations: these follow the procedure outlined at the beginning of Section 5, and are essentially the same as in the proof of Theorem 3.
5.4.1 Segre type [2,1,1]

One can show that this case leads to constant coefficient operators.

5.4.2 Segre type [2,2]

By Theorem 7, we have to consider two different cases.

Case 1: There exists a coordinate system where $g$ and $\tilde{g}_0$ take the form

$$g^{ij} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \quad \tilde{g}_0^{ij} = \begin{pmatrix} 1 & \lambda & 0 & 0 \\ \lambda & 0 & 0 & 0 \\ 0 & 0 & 1 & \lambda \\ 0 & 0 & \lambda & 0 \end{pmatrix}.$$

The general solution of Mokhov’s conditions is given by $\tilde{g} = \sum_{i=1}^4 \kappa_i \tilde{g}_i + \tilde{g}_0$, where $\kappa_i$ are arbitrary constants, and the bivectors $\tilde{g}_i$ are as follows:

$$\tilde{g}_1 = \begin{pmatrix} u^1 & -\frac{1}{2}u^2 & \frac{1}{2}u^3 & 0 \\ -\frac{1}{2}u^2 & 0 & 0 & 0 \\ \frac{1}{2}u^3 & 0 & 0 & -\frac{1}{2}u^2 \\ 0 & 0 & -\frac{1}{2}u^2 & 0 \end{pmatrix}, \quad \tilde{g}_2 = \begin{pmatrix} u^4 & 0 & -\frac{1}{2}u^2 & 0 \\ 0 & 0 & 0 & 0 \\ -\frac{1}{2}u^2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\tilde{g}_3 = \begin{pmatrix} 0 & \frac{1}{2}u^4 & -\frac{1}{2}u^3 & 0 \\ -\frac{1}{2}u^4 & 0 & 0 & 0 \\ \frac{1}{2}u^3 & 0 & -u^3 & \frac{1}{2}u^4 \\ 0 & 0 & \frac{1}{2}u^4 & 0 \end{pmatrix}, \quad \tilde{g}_4 = \begin{pmatrix} 0 & 0 & \frac{1}{2}u^4 & 0 \\ 0 & 0 & 0 & 0 \\ \frac{1}{2}u^4 & 0 & -u^2 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

The eigenvalue of the corresponding affinor $L$ is $\frac{1}{2}(\kappa_3 u^4 - \kappa_1 u^2) + \lambda$. Using transformations that preserve both $g$ and $\tilde{g}_0$ one can set the coefficients $\kappa_3$ and $\kappa_4$ equal to zero, arriving at the normal form

$$\tilde{g} = \kappa_1 \tilde{g}_1 + \kappa_2 \tilde{g}_2 + \tilde{g}_0.$$

Case 2: There exists a coordinate system where $g$ and $\tilde{g}_0$ take the form

$$g^{ij} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & -1 & 0 \end{pmatrix}, \quad \tilde{g}_0^{ij} = \begin{pmatrix} 1 & \lambda & 0 & 0 \\ \lambda & 0 & 0 & 0 \\ 0 & 0 & -1 & -\lambda \\ 0 & 0 & -\lambda & 0 \end{pmatrix}.$$

The eigenvalue of the corresponding affinor $L$ is $\frac{1}{2}(\kappa_3 u^4 - \kappa_1 u^2) + \lambda$. The general solution of Mokhov’s conditions is given by $\tilde{g} = \sum_{i=1}^4 \kappa_i \tilde{g}_i + \tilde{g}_0$, where $\kappa_i$ are arbitrary
constants, and the bivectors \( \tilde{g}_i \) are as follows:

\[
\tilde{g}_1 = \begin{pmatrix}
  u^1 & -\frac{1}{2}u^2 & \frac{1}{2}u^3 & 0 \\
  -\frac{1}{2}u^2 & 0 & 0 & 0 \\
  \frac{1}{2}u^3 & 0 & 0 & \frac{1}{2}u^2 \\
  0 & 0 & \frac{1}{2}u^2 & 0
\end{pmatrix},
\]
\[
\tilde{g}_2 = \begin{pmatrix}
  u^4 & 0 & \frac{1}{2}u^2 & 0 \\
  0 & 0 & 0 & 0 \\
  \frac{1}{2}u^2 & 0 & 0 & 0 \\
  0 & 0 & 0 & 0
\end{pmatrix},
\]
\[
\tilde{g}_3 = \begin{pmatrix}
  0 & \frac{1}{2}u^4 & \frac{1}{2}u^1 & 0 \\
  \frac{1}{2}u^4 & 0 & 0 & 0 \\
  \frac{1}{2}u^1 & 0 & u^3 & -\frac{1}{2}u^4 \\
  0 & 0 & -\frac{1}{2}u^4 & 0
\end{pmatrix},
\]
\[
\tilde{g}_4 = \begin{pmatrix}
  0 & 0 & \frac{1}{2}u^4 & 0 \\
  0 & 0 & 0 & 0 \\
  0 & 0 & 0 & 0 \\
  0 & 0 & 0 & 0
\end{pmatrix}.
\]

Using transformations that preserve both \( g \) and \( \tilde{g}_0 \) one can reduce the above four-parameter family to one of the following normal forms:

\[
\tilde{g} = \tilde{g}_0 + \begin{cases}
  \kappa_1 \tilde{g}_1 + \kappa_2 \tilde{g}_4 \\
  \kappa_1 \tilde{g}_2 + \kappa_2 \tilde{g}_3 \\
  \tilde{g}_2 \pm \tilde{g}_4 \\
  \tilde{g}_1 \pm \tilde{g}_3 + \kappa_1 \tilde{g}_4
\end{cases},
\]
\[\kappa_1, \kappa_2 = \text{const.}\]

### 5.4.3 Segre type \([3,1]\)

Here we also have two different cases.

**Case 1:** There exists a coordinate system where \( g \) and \( \tilde{g}_0 \) take the form

\[
g^{ij} = \begin{pmatrix}
  0 & 0 & 1 & 0 \\
  0 & 1 & 0 & 0 \\
  1 & 0 & 0 & 0 \\
  0 & 0 & 0 & 1
\end{pmatrix},
\]
\[
\tilde{g}_0^{ij} = \begin{pmatrix}
  0 & 1 & \lambda & 0 \\
  1 & \lambda & 0 & 0 \\
  \lambda & 0 & 0 & 0 \\
  0 & 0 & \lambda & 0
\end{pmatrix}.
\]

The general solution of Mokhov’s conditions is given by \( \tilde{g} = \sum_{i=1}^{4} \kappa_i \tilde{g}_i + \tilde{g}_0 \), where \( \kappa_i \) are arbitrary constants, and the bivectors \( \tilde{g}_i \) are as follows:

\[
\tilde{g}_1 = \begin{pmatrix}
  2u^1 & \frac{1}{2}u^2 & -u^3 & \frac{1}{2}u^4 \\
  \frac{1}{2}u^2 & -u^3 & 0 & 0 \\
  -u^3 & 0 & 0 & 0 \\
  \frac{1}{2}u^4 & 0 & 0 & -u^3
\end{pmatrix},
\]
\[
\tilde{g}_2 = \begin{pmatrix}
  u^2 & -\frac{1}{2}u^3 & 0 & 0 \\
  -\frac{1}{2}u^3 & 0 & 0 & 0 \\
  0 & 0 & 0 & 0 \\
  0 & 0 & 0 & 0
\end{pmatrix},
\]
\[
\tilde{g}_3 = \begin{pmatrix}
  u^4 & 0 & 0 & \frac{1}{2}u^3 \\
  0 & 0 & 0 & 0 \\
  0 & 0 & 0 & 0 \\
  \frac{1}{2}u^3 & 0 & 0 & 0
\end{pmatrix},
\]
\[
\tilde{g}_4 = \begin{pmatrix}
  0 & \frac{1}{2}u^4 & 0 & \frac{1}{2}u^2 \\
  \frac{1}{2}u^4 & 0 & 0 & 0 \\
  0 & 0 & 0 & 0 \\
  \frac{1}{2}u^2 & 0 & 0 & 0
\end{pmatrix}.
\]
The eigenvalue of the corresponding affinor $L$ is $\lambda - \kappa_1 u^3$. Using transformations that preserve both $g$ and $\tilde{g}_0$ one can bring the above four-parameter family to one of the following canonical forms:

$$\tilde{g} = \tilde{g}_0 + \begin{cases} 
\kappa_1 \tilde{g}_2 + \kappa_2 \tilde{g}_3 \\
\kappa_1 \tilde{g}_3 + \kappa_2 \tilde{g}_4 \\
\kappa_1 \tilde{g}_1 + \kappa_2 \tilde{g}_2 + \kappa_3 \tilde{g}_4
\end{cases} \quad \kappa_1, \kappa_2, \kappa_3 = \text{const.}$$

**Case 2:** There exists a coordinate system where $g$ and $\tilde{g}_0$ take the form

$$g_{ij} = \begin{pmatrix} 0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 \end{pmatrix}, \quad \tilde{g}_0^{ij} = \begin{pmatrix} 0 & 1 & \lambda & 0 \\
1 & \lambda & 0 & 0 \\
\lambda & 0 & 0 & 0 \\
0 & 0 & 0 & -\lambda \end{pmatrix}.$$ 

The general solution of Mokhov’s conditions is given by $\tilde{g} = \sum_{i=1}^{4} \kappa_i \tilde{g}_i + \tilde{g}_0$, where $\kappa_i$ are arbitrary constants, and the bivectors $\tilde{g}_i$ are as follows:

$$\tilde{g}_1 = \begin{pmatrix} u^4 & 0 & 0 & \frac{1}{2} u^3 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
\frac{1}{2} u^3 & 0 & 0 & 0 \end{pmatrix}, \quad \tilde{g}_2 = \begin{pmatrix} u^2 & -\frac{1}{2} u^3 & 0 & 0 \\
-\frac{1}{2} u^3 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \end{pmatrix},$$

$$\tilde{g}_3 = \begin{pmatrix} 0 & \frac{1}{2} u^4 & 0 & \frac{1}{2} u^2 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
\frac{1}{2} u^2 & 0 & 0 & 0 \end{pmatrix}, \quad \tilde{g}_4 = \begin{pmatrix} 0 & \frac{1}{2} u^4 & 0 & \frac{1}{2} u^2 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
\frac{1}{2} u^2 & 0 & 0 & 0 \end{pmatrix}.$$ 

The eigenvalue of the corresponding affinor $L$ is $\lambda - \kappa_1 u^3$. Using transformations that preserve both $g$ and $\tilde{g}_0$ one can bring the above four-parameter family to one of the following normal forms:

$$\tilde{g} = \tilde{g}_0 + \begin{cases} 
\kappa_1 \tilde{g}_2 + \kappa_2 \tilde{g}_3 \\
\kappa_1 \tilde{g}_3 + \kappa_2 \tilde{g}_4 \\
\kappa_1 \tilde{g}_1 + \kappa_2 \tilde{g}_2 + \kappa_3 \tilde{g}_4
\end{cases} \quad \kappa_1, \kappa_2, \kappa_3 = \text{const.}$$

5.4.4 Segre type [4]

This is the case where the corresponding affinor $L$ is a single Jordan block (see Section 6 for the general theory). There exists a coordinate system where $g$ and $\tilde{g}_0$ take the form

$$g^{ij} = \begin{pmatrix} 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0 \end{pmatrix}, \quad \tilde{g}_0^{ij} = \begin{pmatrix} 0 & 0 & 1 & \lambda \\
0 & 1 & \lambda & 0 \\
1 & \lambda & 0 & 0 \\
\lambda & 0 & 0 & 0 \end{pmatrix}.$$
It turns out that the general solution of Mokhov’s conditions is
\[ \tilde{g} = \sum_{i=1}^{3} \kappa_i \tilde{g}^i + \tilde{g}_0 \]
where \( \kappa_i \) are arbitrary constants, and the bivectors \( \tilde{g}_i \) are as follows:

\[ \tilde{g}_1 = \begin{pmatrix} -u^1 & -\frac{1}{2}u^2 & 0 & \frac{1}{2}u^4 \\ -\frac{1}{2}u^2 & 0 & \frac{1}{2}u^4 & 0 \\ 0 & \frac{1}{2}u^4 & 0 & 0 \\ \frac{1}{2}u^4 & 0 & 0 & 0 \end{pmatrix}, \quad \tilde{g}_2 = \begin{pmatrix} 2u^2 & \frac{1}{2}u^3 & -u^4 & 0 \\ \frac{1}{2}u^3 & -u^4 & 0 & 0 \\ -u^4 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \tilde{g}_3 = \begin{pmatrix} u^3 & -\frac{1}{2}u^4 & 0 & 0 \\ -\frac{1}{2}u^4 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \]

Here the eigenvalue of the affinor \( L \) is \( \frac{1}{2} \kappa_1 u^4 + \lambda \). Using transformations that preserve both \( g \) and \( \tilde{g}_0 \) one can bring the above three-parameter family to one of the following normal forms: in the non-constant eigenvalue case, to

\[ \tilde{g} = \tilde{g}_0 + \kappa_1 \tilde{g}_1, \quad \kappa_1 = \text{const}, \]

while in the constant eigenvalue case, to

\[ \tilde{g} = \tilde{g}_0 + \left\{ \begin{array}{c} \tilde{g}_2, \\ \kappa_1 \tilde{g}_3 \end{array} \right\} \quad \kappa_1 = \text{const}. \]

### 5.4.5 Complex conjugate case

In the case of two pairs of complex conjugate eigenvalues \( \nu + i\lambda \) and \( \nu - i\lambda \), there exists a coordinate system such that

\[ g^{ij} = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}, \quad \tilde{g}^{ij} = \begin{pmatrix} 0 & 1 & -\lambda & \nu \\ 1 & 0 & \nu & \lambda \\ -\lambda & \nu & 0 & 0 \\ \nu & \lambda & 0 & 0 \end{pmatrix}. \]

The general solution of Mokhov’s conditions is \( \tilde{g} = \kappa_1 \tilde{g}_1 + \kappa_2 \tilde{g}_2 + \tilde{g}_0 \) where \( \kappa_i \) are arbitrary constants, and the bivectors \( \tilde{g}_i \) are as follows:

\[ \tilde{g}_1 = \begin{pmatrix} 2u^2 & -2u^1 & -u^4 & u^3 \\ -2u^1 & -2u^2 & u^3 & u^4 \\ -u^4 & u^3 & 0 & 0 \\ u^3 & u^4 & 0 & 0 \end{pmatrix}, \quad \tilde{g}_2 = \begin{pmatrix} 2u^1 & 2u^2 & -u^3 & -u^4 \\ 2u^2 & -2u^1 & -u^4 & u^3 \\ -u^3 & -u^4 & 0 & 0 \\ -u^4 & u^3 & 0 & 0 \end{pmatrix}. \]

Using transformations that preserve the form of \( g \) one can eliminate \( \tilde{g}_0 \), and bring \( \tilde{g} \) to the normal form

\[ \tilde{g}^{ij} = \begin{pmatrix} 2u^2 & -2u^1 & -u^4 & u^3 \\ -2u^1 & -2u^2 & u^3 & u^4 \\ -u^4 & u^3 & 0 & 0 \\ u^3 & u^4 & 0 & 0 \end{pmatrix}. \]
The eigenvalues of the corresponding affinor $L$ are $u^3 \pm iu^4$. Note that this case is a complexification of the two-component operator (1.8), which can be achieved via the following recipe (see [1] for more details): each complex entry $a + ib$ of $g^C$ and $\tilde{g}^C$ is replaced by the $2 \times 2$ block

\[
\begin{pmatrix}
-b & a \\
 a & b
\end{pmatrix},
\]

where $g^C$ and $\tilde{g}^C$ are the complexified bivectors of the operator (1.8):

\[
g^C = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \tilde{g}^C = \begin{pmatrix} -2z^1 & z^2 \\ z^2 & 0 \end{pmatrix},
\]

$z^1 = u^1 + iu^2, \ z^2 = u^3 + iu^4$.

6 The single Jordan block case

Let us begin with examples of $n$-component Hamiltonian operators of the single Jordan block type.

Example 1. One of the most important examples was discovered by Mokhov [16]. Here the first $n \times n$ contravariant metric is constant and anti-diagonal,

\[
g = \begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix},
\]

while the second contravariant metric $\tilde{g}$ is defined as follows:

\[
\tilde{g}^{ij} = (b^{ij}_k + b^{ji}_k)u^k, \quad \left\{ \begin{array}{ll}
b^{ij}_k = 0 & \text{if } k \neq i + j - 1, \\
b^{ij}_{i+j-1} = 3j - n - 2 & \text{otherwise.}
\end{array} \right.
\]

One can verify that the Jordan normal form for the corresponding affinor $L$ is a single Jordan block with non-constant eigenvalue (for any $n \neq 4$: in the exceptional case $n = 4$ the affinor $L$ is the sum of two $2 \times 2$ Jordan blocks). We will refer to this case as the Mokhov operator. The affinor $L$ is given by

\[
L^i = [3(i - j) + n - 1]u^{n+i-j}.
\]

The equivalent form for $\tilde{g}$ is

\[
\tilde{g}^{ij} = [3(i + j) - 2(n + 2)]u^{i+j-1},
\]

for $i + j - 1 \leq n$, and 0 otherwise (in what follows, we use the following convention: if $\alpha > n$ then $u^\alpha \equiv 0$). For $n = 2, 3, 4$ the explicit form of $\tilde{g}$ is as follows:

\[
\tilde{g} = \begin{pmatrix} -2u^1 & u^2 \\ u^2 & 0 \end{pmatrix}, \quad \tilde{g} = \begin{pmatrix} -4u^1 & -u^2 & 2u^3 \\ -u^2 & 2u^3 & 0 \\ 2u^3 & 0 & 0 \end{pmatrix}, \quad \tilde{g} = \begin{pmatrix} -6u^1 & -3u^2 & 0 & 3u^3 \\ -3u^2 & 0 & 3u^3 & 0 \\ 0 & 3u^3 & 0 & 0 \\ 3u^3 & 0 & 0 & 0 \end{pmatrix}.
\]
Example 2. Another $n$-component example has $g$ the same as in Example 1, while the second contravariant metric is

$$
\tilde{g}^{ij} = (b_k^{ij} + b_k^{ji})u^k + \lambda g^{ij}, \quad \begin{cases} 
   b_k^{ij} = 0 & \text{if } k \neq i + j, \\
   b_k^{i,j} = 3j - n - 1 & \text{otherwise},
\end{cases}
$$

$\lambda = \text{const}$. One can verify that this pair of contravariant metrics defines a Hamiltonian operator for any $n \geq 3$ (the case $n = 2$ is trivial since all $b_k^{ij}$ vanish). The corresponding affinor $L$ is a single Jordan block with constant eigenvalue $\lambda$. For instance, for $n = 3, 4$ the second contravariant metric reads

$$
\tilde{g} = \begin{pmatrix}
-2u^2 & u^3 & \lambda \\
u^3 & \lambda & 0 \\
\lambda & 0 & 0
\end{pmatrix}, \quad \tilde{g} = \begin{pmatrix}
-4u^2 & -u^3 & 2u^4 & \lambda \\
-u^3 & 2u^4 & \lambda & 0 \\
2u^4 & \lambda & 0 & 0 \\
\lambda & 0 & 0 & 0
\end{pmatrix}.
$$

The aim of this section is to give a complete description of the case where the affinor $L$ is a single Jordan block. We will see that the Mokhov example plays fundamental role in this picture. To formulate our main result, let us introduce symmetric bivectors $\mu^{(n;k)}$ as follows:

$$
\mu^{(n;k)} = [3(i + j) - 2(n + 2 - k)]u^{i+j-1+k}.
$$

(6.1)

In particular, $\mu^{(n;0)}$ coincides with the second contravariant metric $\tilde{g}$ of the Mokhov operator from Example 1. Note also that $\mu^{(n;k)} = 0$ for $k > n - 2$. Let us present the explicit form for some $\mu^{(n;k)}$:

$$
\mu^{(3;1)} = \begin{pmatrix}
-2u^2 & u^3 & 0 \\
u^3 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}, \quad \mu^{(4;1)} = \begin{pmatrix}
-4u^2 & -u^3 & 2u^4 & 0 \\
-u^3 & 2u^4 & 0 & 0 \\
2u^4 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix},
$$

$$
\mu^{(4;2)} = \begin{pmatrix}
-2u^3 & u^4 & 0 & 0 \\
u^4 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix}.
$$

We will show that in the case when the affinor $L$ is a single Jordan block, the general solution of Mokhov’s conditions reads

$$
\tilde{g} = \tilde{g}_0 + \sum_{m=0}^{n-2} \xi_m \mu^{(n;m)},
$$

(6.2)
where $\xi_m$ are arbitrary constants, and
\[
g = \pm \begin{pmatrix} & & \cdots & 1 \\ \vdots & & & \vdots \\ 1 & & & 1 \\ \end{pmatrix}, \quad \tilde{g}_0 = \pm \begin{pmatrix} & & \cdots & \lambda \\ \vdots & & & \vdots \\ 1 & & & \lambda \\ \end{pmatrix}.
\]

Here the eigenvalue of $L$ equals $\xi_0(n - 1)u^n + \lambda$. In the non-constant eigenvalue case, $\xi_0 \neq 0$, we have the following result:

**Theorem 4.** Let $P$ be Hamiltonian operator (1.2) such that the affinor $L = \tilde{g}g^{-1}$ is a single $n \times n$ Jordan block with non-constant eigenvalue. Then there exists a coordinate system in which $g$ and $\tilde{g}$ can be reduced to the following canonical forms:

\[
g = \pm \begin{pmatrix} & & \cdots & 1 \\ \vdots & & & \vdots \\ 1 & & & 1 \\ \end{pmatrix}, \quad \tilde{g} = \pm \begin{cases} 
\mu^{(n;0)} & \text{if } n \neq 1 \mod 3, \\
\mu^{(n;0)} + \kappa_1 \mu^{(n;-n+1)} & \text{if } n \equiv 1 \mod 3, n \neq 4, \\
\mu^{(4;0)} + \kappa_1 \mu^{(4;1)} + \tilde{g}_0 & \text{if } n = 4.
\end{cases}
\]

Here $\kappa_1$ is an arbitrary constant.

In the constant eigenvalue case, $\xi_0 = 0$, we have several canonical forms depending on how many coefficients among $\xi_i$ are equal to zero:

**Theorem 8** (Constant eigenvalue case). Suppose $\xi_i = 0$ for $i = 0, \ldots, \alpha - 1$. Then family (6.2) can be reduced to

\[
\tilde{g} = \mu^{(n;\alpha)} + \kappa \mu^{(n;\alpha+m)} + \tilde{g}_0, \quad m = \frac{n - 1 + 2\alpha}{3},
\]

if $m \in \mathbb{N}$, otherwise to

\[
\tilde{g} = \mu^{(n;\alpha)} + \tilde{g}_0.
\]

### 6.1 Proof of Theorem 4

The idea of the proof is as follows: first, we find the general solution of Mokhov’s equations. It turns out (Proposition 3) that this solution depends on $n - 1$ parameters. Using orthogonal transformations, we then reduce this $(n - 1)$-parameter family to various normal forms (Lemma 4 and Proposition 4). We will work in coordinates where $g$ and $\tilde{g}_0$ take canonical form

\[
g = \pm \begin{pmatrix} & & \cdots & 1 \\ \vdots & & & \vdots \\ 1 & & & 1 \\ \end{pmatrix}, \quad \tilde{g}_0 = \pm \begin{pmatrix} & & \cdots & \lambda \\ \vdots & & & \vdots \\ 1 & & & \lambda \\ \end{pmatrix}.
\]
For definiteness, we will consider the + sign. In what follows we will need the following result:

**Proposition 2.** The Killing vectors of \( g \) are the following \( \frac{1}{2} n(n-1) \) vector fields:

\[
X_{(\alpha, \beta)} = u^\alpha \partial_\beta - u^{n+1-\beta} \partial_{n+1-\alpha}, \quad X_\gamma = \partial_\gamma,
\]

here \( \alpha + \beta < n + 1 \), and \( \partial_\alpha = \partial_{u^\alpha} \).

The affinor \( L \) and the metric \( \tilde{g} \) are given by

\[
L^{i}_{\ j} = c^{i}_{jk} u^k + \tilde{g}^{i}_{lj}, \\
\tilde{g}^{ij} = L^{i}_{l} g^{lj} = c^{i}_{n+1-j,k} u^k + \tilde{g}^{ij}.
\]

These have to satisfy a set of constraints (note that the vanishing of the Nijenhuis torsion, \( \mathcal{N}(L) = 0 \), gives two types of relations: linear and quadratic in \( c^{i}_{jk} \):

- **Linear part of the condition** \( \mathcal{N}(L) = 0 \) reads
  \[
c^{k}_{j,i-1} - c^{k}_{i,j-1} + c^{k+1}_{i} - c^{k+1}_{j} = 0; \tag{6.3}
\]

- **Quadratic part of the condition** \( \mathcal{N}(L) = 0 \) reads
  \[
c^{s}_{it} c^{m}_{js} - c^{s}_{jt} c^{m}_{is} + c^{m}_{sl} c^{s}_{lj} - c^{m}_{sl} c^{s}_{ji} = 0;
\]

- **Symmetry of \( \tilde{g} \) gives**
  \[
c^{n+1-i}_{jk} = c^{n+1-j}_{ik}, \tag{6.4}
\]

- **The Killing condition gives**
  \[
c^{n+1-i}_{jk} + c^{n+1-k}_{ij} + c^{n+1-j}_{ki} = 0. \tag{6.5}
\]

Remarkably, linear system (6.3)-(6.5) can be solved explicitly:

**Proposition 3.** The general solution of linear system (6.3)-(6.5) is given by (6.2),

\[
\tilde{g} = \tilde{g}_0 + \sum_{m=0}^{n-2} \xi_m \mu^{(n,m)},
\]

where \( \xi_m \) are arbitrary constants. The eigenvalue of the corresponding affinor \( L \) is \( \xi_0(n-1)u^n + \lambda \).

**Proof:**
The key observation allowing one to prove Proposition 3 by induction is as follows. Suppose $c_{ji}^n = 0$. In this case it is easy to see that $c_{1i}^k$ and $c_{j1}^k$ must also vanish, indeed, from (6.4) we have
\[ c_{ik}^{n+1-j} = c_{jk}^n, \]
and from (6.5) and (6.4) we obtain
\[ c_{ik}^{n+1-j} + c_{1j}^{n+1-k} + c_{k1}^{n+1-j} = 0. \]
Then the remaining equations for $c_{ij}^k$ with $i, j = 2, ..., n$ and $k = 1, ..., n-1$, coincide with the system one obtains in the $(n - 1)$-component case with $\tilde{c}_{ij}^k = c_{i-1,j-1}^k$, allowing one to use inductive assumption.

Our strategy will be the following: first we show that the above equations imply $c_{ji}^n = 0$, $c_{1i}^k = 0$ and $c_{j1}^k = 0$ apart from $c_{mn}^n = c$, $c_{1n}^1 = c$ and $c_{n1}^1 = -2c$. We already know a solution with $c \neq 0$, which comes from Mokhov’s example. The generic solution can be written as a linear combination of Mokhov’s solution and a solution of the system with $c_{ji}^n = c_{1i}^k = c_{j1}^k = 0$ (in which case we can use inductive assumption as outlined above).

From (6.4) and (6.3) we have (for $j \neq 1$)
\[ c_{1,j-1}^k = c_{n+1-k,j-1}^n = c_{j,n-k}^n. \]
Using this identity we can write (6.3) as
\[ c_{j,n-k}^n - c_{1j}^{k+1} + c_{j1}^{k+1} = 0. \]
Similarly, from (6.5) we obtain
\[ c_{j,n-k}^n + c_{j1}^{k+1} + c_{1j}^{k+1} = 0. \]
Combining these two conditions we get $c_{ij}^1 = 0$, for any $i \neq 1, j \neq 1$. Writing out (6.5) with $j = k = 1$ we get
\[ c_{11}^{n+1-i} + c_{1i}^n + c_{i1}^n = 2c_{11}^{n+1-i} + c_{1i}^n = 0, \]
which implies $c_{11}^k = 0$. Summarizing, we have
\[ c_{ij}^1 = 0, \quad \forall i \neq 1, \]
which, for symmetry reasons, implies
\[ c_{jk}^n = 0, \quad \forall j \neq n, \]
and
\[ c_{j1}^i = 0, \quad \forall i \neq 1, j \neq n. \]
Our next remark is that $c_{1j}^1 = 0$ for $j = 1, \ldots, n - 2$. This follows from (6.3) evaluated at $k = i = 1$,
\[ c_{1,j-1}^1 - c_{1,j}^2 + c_{j1}^2 = 0. \]
This readily implies $c_{n,k}^n = 0$ and $c_{k,1}^1 = 0$ for $k = 1, \ldots, n - 2$, as well as $c_{n,1}^k = 0$ for $k = 3, \ldots, n$. It is also easy to see that the three non-vanishing coefficients $c_{nn}^n, c_{1n}^1, c_{n1}^1$ are related by
\[ c_{nn}^n = c_{1n}^1, \quad c_{n1}^1 = -2c_{1n}^1. \]

We still need to prove that $c_{1,n-1}^1 = 0$. Due to the above computations the first column of the affinor $L$ has the form $(\nu, 0, \ldots, 0)^t$ where $\nu = c_{1,n-1}^1 u^{n-1} + c_{1n}^1 u^n + \lambda$ is the (unique) eigenvalue of $L$. Similarly, the last row of $L$ is given by $(0, \ldots, 0, \nu)$. Let us denote by $(e^{(1)}, \ldots, e^{(n)})$ the canonical frame of the pair $(L, g)$. Thus,
\begin{equation}
L_k e^k = \nu e^i + e^{(p-1)}, \quad (6.6)
\end{equation}

It follows from the vanishing of the Nijenhuis torsion of $L$ that $e_{(i)}(\nu) = 0$ for $i = 1, \ldots, n - 1$, where $e_{(i)}(\nu)$ denotes the Lie derivative of $\nu$ in direction $e^{(i)}$, see [1]. Due to the form of the affinor we have (set $i = n$ in (6.6)):
\[ e_{(p)}^n = 0, \quad p = 1, \ldots, n - 1. \]
This means that $e^{(1)}, \ldots, e^{(n-1)}$ do not contain $\frac{\partial}{\partial u^n}$, and thus $\nu$ must depend on $u^n$ only, so that $c_{1,n-1}^1 = 0$.

This proves that the general solution is given by (6.2). Direct computations shows that (6.2) also satisfies the quadratic conditions coming from $\mathcal{N}(L) = 0$. ■

Thus, the general solution depends on $n - 1$ parameters. At this point one might wonder whether this number can be reduced. The answer is yes, the list of normal forms is presented below. In order to proceed, we need the following statement.

**Lemma 3.** The $n - 2$ vector fields $X^{(k)} = \sum_{i=1}^{n-k} (n - k + 1 - 2i)u^{i+k} \partial_i$, where $k = 1, \ldots, n - 2$, satisfy the relations

1. $\mathcal{L}_{X^{(k)}} g = 0$ (thus, they are isometries of $g$),
2. $\mathcal{L}_{X^{(k)}} \mu^{(n;\alpha)} = p_{[n,k,\alpha]} \mu^{(n;\alpha+k)}$,
3. $\mathcal{L}_{X^{(k)}} \mu^{(n;\alpha)} = \left( \prod_{s=0}^{m-1} (p_{[n,k,\alpha]} - 2ks) \right) \mu^{(n;\alpha+mk)}$,

where the coefficients $p_{[n,k,\alpha]}$ are defined as $p_{[n,k,\alpha]} = 3k + 1 - n - 2\alpha$.

The proof of this lemma is a straightforward computation.

29
Consider now the general solution (6.2). Note that in the non-constant eigenvalue case, \( \xi_0 \neq 0 \), one can eliminate the constant term \( \tilde{g}_0 \) by a translation of variables \( u^i \). Let \( S_0 \) be the resulting \( n - 1 \) parameter family of solutions,

\[
S_0 = \sum_{i=0}^{n-2} \xi_i \mu^{(n;i)},
\]

(6.7)

and let \( L_{[k]} \) be the Lie series

\[
L_{[k]} = \exp(t_k L X_{(k)}) = \sum_{s \geq 0} \frac{t_k^s}{s!} L^s X_{(k)},
\]

where \( X_{(k)} \) are as in Lemma 3. We point out that, when applied to \( \mu^{(n;k)} \) for \( n \) fixed, \( L_{[k]} \) consists of a finite number of terms: recall that \( \mu^{(n;i)} = 0 \) for \( i > n - 2 \).

**Lemma 4.** If \( \xi_0 \neq 0 \), then it can be set equal to one.

**Proof:**

Let us consider the scaling transformation

\[
u^i = \gamma^{n+1 \over 2} u^i,
\]

where \( \gamma \neq 0 \) is an arbitrary constant. It is easy to see that this preserves the form of \( g \). Direct calculation gives

\[
\mu^{(n;k)ij}(u) \partial_{u^i} \partial_{u^j} = \gamma^{n+1 \over 2} + k \mu^{(n;k)ij}(v) \partial_{v^i} \partial_{v^j}.
\]

Thus, setting \( \gamma = \xi_0^{-1} \), we can reduce the coefficient of \( \mu^{(n;0)} \) to 1.

To finish the proof of Theorem 4 we need the following

**Proposition 4.** Suppose \( \xi_0 \neq 0 \). Then

1. if \( n \not\equiv 1 \mod 3 \), there exists an orthogonal transformation which brings the \( (n - 1) \)-parameter solution \( S_0 \) to \( \mu^{(n;0)} \);

2. if \( n \equiv 1 \mod 3 \), \( n \neq 4 \), there exists an orthogonal transformation which brings \( S_0 \) to the one-parameter family \( \mu^{(n;0)} + \kappa \mu^{(n;2\mathbf{2})} \),

where \( \kappa \) is an arbitrary constant.

**Proof:**
By Lemma 4 we can consider the family $S_0$ in the form

$$S_0 = \mu^{(n;0)} + \sum_{i=1}^{n-2} \kappa_i \mu^{(n;i)},$$

where $\kappa_i$ are arbitrary constant coefficients. Suppose $n \not\equiv 1 \mod 3$, then the coefficients $p_{[k,n,0]}$ defined in Lemma 3 do not vanish. Let us apply $L_{[1]}$ to $S_0$ and look at the coefficient of $\mu^{(n;1)}$:

$$L_{[1]}S_0 = S_0 + t_1 L_{X(1)}S_0 + \frac{t_1^2}{2} L_{X(1)}^2 S_0 + \ldots + \frac{t_1^{n-2}}{(n-2)!} L_{X(1)}^{n-2} S_0$$

$$= \mu^{(n;0)} + (\kappa_1 + t_1 p_{[n,1,0]}) \mu^{(n;1)} + \ldots$$

We can always choose $t_1$ such that the coefficient of $\mu^{(n;1)}$ is zero. Let us call $S_1$ the resulting $(n-2)$-parameter family:

$$S_1 = L_{[1]}S_0 |_{t_1=-\frac{\kappa_1}{p_{[n,1,0]}}} = \mu^{(n;0)} + \sum_{i=2}^{n-2} \tilde{\kappa}_i \mu^{(n;i)}.$$

Applying $L_{[2]}$ and looking at the coefficient of $\mu^{(n;2)}$ we obtain

$$L_{[2]}S_1 = \mu^{(n;0)} + (\tilde{\kappa}_2 + t_2 p_{[n,2,0]}) \mu^{(n;2)} + \ldots$$

Again, we can choose $t_2$ such that the coefficient of $\mu^{(n;2)}$ vanishes, and so on. Ultimately, we get

$$L_{[n-2]}L_{[n-3]} \cdots L_{[1]}S_0 = \mu^{(n;0)},$$

as required.

To prove the second part of the proposition, let us set $n = 3m + 1$. It is easy to see that $L_{X(m)} \mu^{(n;0)} = 0$, since the coefficient $p_{[n,m,0]}$ vanishes. Note that in this case $p_{[n,k,0]} \neq 0$ for $k \neq m$. For fixed $m$, until $k = m - 1$ we can apply the same procedure as above, obtaining

$$S_{m-1} = \mu^{(n;0)} + \sum_{i=m}^{n-2} \tilde{\kappa}_i \mu^{(n;i)}.$$

At this point, applying $L_{X(m)}$ to $S_{m-1}$, we cannot eliminate the coefficient of $\mu^{(n;m)}$, since $L_{X(m)} \mu^{(n;0)} = 0$. However, applying $L_{X(m+1)}$ and looking at the coefficient of $\mu^{(n;m+1)}$,

$$L_{[m+1]}S_{m-1} = \mu^{(n;0)} + \tilde{\kappa}_m \mu^{(n;m)} + (\tilde{\kappa}_{m+1} + t_{m+1} p_{[n,m+1,0]}) \mu^{(n;m+1)} + \ldots,$$

we can eliminate it. Following the same method, we arrive at the canonical form

$$S_{\text{can}} = \mu^{(n;0)} + \tilde{\kappa}_m \mu^{(n;m)}.$$
The case \( n = 4 \) is special. Indeed, the \( 4 \times 4 \) Mokhov metric does not correspond to the single Jordan block case. In the \( n = 4 \) Jordan block case, normal forms are presented in Section 5.4. This concludes the proof of Theorem 4. In the constant eigenvalue case, \( \xi_0 = 0 \), we cannot eliminate \( \tilde{g}_0 \) by a shift. Finally, Theorem 8 can be established by following the same procedure as above.

6.2 Relation to Frobenius manifolds

In this Section we demonstrate the relation of Mokhov’s Hamiltonian operator to the trivial Frobenius manifold associated with the cohomology ring of projective space. For this purpose let us briefly recall the definition of a Frobenius manifolds.

**Definition 9.** A Frobenius manifold \((M, g, \circ, e, E)\) is a manifold \(M\) endowed with a (pseudo)-metric \(g\), a product \(\circ\) on the tangent spaces \(T_u M\) and a pair of vector fields \(e\) and \(E\) such that

- the product \(\circ\) is commutative and associative:
  
  \[
  c_{jk}^i = c_{kj}^i, \quad c_{jl}^i c_{kh}^j = c_{kl}^i c_{jh}^j.
  \]

- \(g\) is flat, invariant with respect to \(\circ\),
  
  \[
  g_{ik} c_{jl}^k = g_{jk} c_{il}^k,
  \]

  and the associated Levi-Civita connection \(\nabla\) is compatible with \(\circ\):
  
  \[
  \nabla c_{jk}^i = \nabla c_{ik}^j.
  \] (6.8)

This implies that there exists a function \(F\), called the Frobenius potential, such that, in the flat coordinates for \(g\),

\[
C_{ijk} = g_{il} c_{jk}^l = \partial_i \partial_j \partial_k F.
\]

- The product \(\circ\) has a unity \(e\) which is flat: \(\nabla e = 0\).
- The Euler vector field \(E\) satisfies:
  
  \[
  \nabla \nabla E = 0, \quad \text{Lie}_E e = -E, \quad \text{Lie}_E \circ = 0, \quad \text{Lie}_E g = (2 - d)g,
  \]

for some constant \(d\). The existence of the Euler vector field is related to the existence of a flat contravariant metric called the intersection form. In local coordinates it is defined by the formula

\[
\tilde{g}^{ij} = g^{il} c_{lk}^i E_k.
\]
If, in the flat coordinates for $g$, the functions $c^i_{jk}$ are constant, the Frobenius manifold is called trivial [6]. In this case, the Frobenius potential is a cubic polynomial, $F = \frac{1}{6} c^i_{ijk} u^i u^j u^k$. We now define the trivial Frobenius manifold associated with Mokhov’s Hamiltonian operator.

**Theorem 10.** The metric

\[ g_{ij} = \begin{cases} 
1 & \text{if } i + j = n + 1 \\
0 & \text{otherwise}
\end{cases} , \]

the structure constants

\[ c^i_{jk} = g^{il} c_{ljk} = \begin{cases} 
1 & \text{if } l = 2n + 1 - j - k = n + 1 - i \text{ that is } j + k - i = n \\
0 & \text{otherwise}
\end{cases} , \]

the unity $e = \frac{\partial}{\partial u^n}$, and the Euler vector field $E = \sum_{k=1}^{n}(3k - 2n - 1)u^k \frac{\partial}{\partial u^k}$ define a trivial Frobenius manifold with $d = 3$. Moreover, the intersection form,

\[ \tilde{g}^{ij} = g^{il} c_{ljk} E^k = \begin{cases} 
[3(i + j) - 2n - 4]u^{i+j-1} & \text{if } i + j - 1 \leq n \\
0 & \text{otherwise}
\end{cases} , \]

coincides with the second metric of Mokhov’s operator.

The proof is a straightforward computation.

To conclude this section we compare the Frobenius algebra underlying Mokhov’s example with the Frobenius algebra structure on the full cohomology ring of projective space $H^*(\mathbb{CP}^d)$. This can be defined with respect to the natural basis

\[ e_1 = 1, \ e_2 = \omega, \ldots, \ e_{d+1} = \omega^d, \]

generated by powers of the standard Kähler form normalized as

\[ \int_{\mathbb{CP}^d} \omega^d = 1. \]

The contravariant components of the metric $g$ and the structure constants $c^i_{jk}$ are defined respectively by

\[ g_{ij} = \begin{cases} 
1 & \text{if } i + j = n + 1 \\
0 & \text{otherwise}
\end{cases} , \]

and

\[ e_j \wedge e_k = c^i_{jk} e_i = e_{j+k-1}, \]

that is,

\[ c^i_{jk} = \begin{cases} 
1 & \text{if } j + k - i = 1 \\
0 & \text{otherwise}
\end{cases} , \]

Putting $i' = n + 1 - i$ we obtain the Frobenius algebra of Mokhov’s example.
7 Hamiltonian operators in higher dimensions: proof of Theorem 5

In this section we consider general $d$-dimensional $n$-component Hamiltonian operators of the form

$$P_{ij} = \sum_{\alpha=1}^{d} \left( g_{ij}^{\alpha}(u) \frac{d}{dx^\alpha} + b_{ij}^{\alpha}(u) u^k \right).$$  \hspace{1cm} (7.1)

Operator of this type is called non-degenerate if a generic linear combination of the bivectors $g^{\alpha}$ is non-degenerate (without any loss of generality we will assume that each $g^{\alpha}$ is non-degenerate: this can always be achieved by a suitable linear transformation of the independent variables $x^{\alpha}$). In the non-degenerate case, Mokhov’s conditions involving the obstruction tensor must be satisfied by each pair of bivectors (see [16] for further details). This implies that each pair $(g^{\beta}, g^{\gamma})$ defines a 2D Hamiltonian operator. For a generic $d$-dimensional Hamiltonian operator, the Mokhov conditions can be reformulated as follows

**Theorem 11.** Suppose $g^{\alpha}$ are flat contravariant metrics. Operator (7.1) defines a $d$-dimensional Hamiltonian operator if and only if for all $\beta \neq \gamma$ the following conditions are fulfilled:

1. Linearity of $g^{\beta}$ in the flat coordinates of $g^{\gamma}$.
2. Vanishing of the Nijenhuis torsion of the affinor $L^{(\beta\gamma)} = g^{\beta}(g^{\gamma})^{-1}$.
3. Killing condition for $g^{\gamma}$ with respect to $g^{\beta}$:

$$\nabla^i g^{kji} + \nabla^k g^{ij\gamma} + \nabla^j g^{ik\gamma} = 0,$$

where $\nabla$ is the Levi-Civita connection of $g^{\beta}$.

**Remark.** It is sufficient to require the flatness of only one of the metrics $g^{\alpha}$. Indeed, let us suppose that $g^{\alpha}$ is flat. Then, since the pair $(g^{\alpha}, g^{\beta})$ defines a 2D Hamiltonian operator for all $\beta$, the linearity, Nijenhuis and Killing conditions imply the flatness of $g^{\beta}$ (see Theorem 2).

It was demonstrated by Mokhov [17] that there exist no non-constant 3D Hamiltonian operators with one or two components. Here we show that there exist only two non-trivial three-component Hamiltonian operators in 3D, namely

**Theorem 5.** Any non-degenerate three-component Hamiltonian operator in 3D, which is not transformable to constant coefficients, can be brought to one of the two canonical forms:

$$P = \begin{pmatrix} \partial_z & 0 & \partial_x \\ 0 & \partial_x & 0 \\ \partial_x & 0 & 0 \end{pmatrix} + \begin{pmatrix} -2u^2\partial_y - u_y^2 & u^3\partial_y + 2u_y^3 & 0 \\ u^3\partial_y - u_y^3 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

34
or
\[
P = \begin{pmatrix}
0 & \partial_x & 0 \\
\partial_x & 0 & 0 \\
0 & 0 & \partial_z
\end{pmatrix} + \begin{pmatrix}
-2u^1 \partial_y - u^1_y & u^2 \partial_y + 2u^2_y & 0 \\
u^2 \partial_y - u^2_y & 0 & 0 \\
0 & 0 & 0
\end{pmatrix},
\]

by a local change of the dependent variables \( u^i \), and a linear transformation of the independent variables \( x, y, z \) (see Theorem 12 for the analogue of this result if one does not allow linear changes of \( x, y, z \)).

**Proof:**

Since we are interested in the non-constant case, we will consider 3D operators as deformation of 2D non-constant operators that have been classified already (Theorem 3). There exist only three such operators, defined by the following pairs of contravariant metrics:

\[
g = \begin{pmatrix}
0 & 0 & 1 \\
0 & 1 & 0 \\
1 & 0 & 0
\end{pmatrix}, \quad \tilde{g} = \begin{pmatrix}
-2u^1 & -\frac{1}{2}u^2 & u^3 \\
-\frac{1}{2}u^2 & u^3 & 0 \\
u^3 & 0 & 0
\end{pmatrix}, \quad (7.2)
\]

\[
g = \begin{pmatrix}
0 & 0 & 1 \\
0 & 1 & 0 \\
1 & 0 & 0
\end{pmatrix}, \quad \tilde{g} = \begin{pmatrix}
-2u^2 & u^3 & \lambda \\
u^3 & \lambda & 0 \\
\lambda & 0 & 0
\end{pmatrix}, \quad (7.3)
\]

and (reducible case)

\[
g = \begin{pmatrix}
0 & 1 & 0 \\
1 & 0 & 0 \\
0 & 0 & 1
\end{pmatrix}, \quad \tilde{g} = \begin{pmatrix}
-2u^1 & u^2 & 0 \\
u^2 & 0 & 0 \\
0 & 0 & \lambda
\end{pmatrix}. \quad (7.4)
\]

Fixing one of the above pairs, let us add a third contravariant metric \( h \). Since we are in the flat coordinates of the first metric \( g \), the bivector \( h \) must be linear. Since the pair \( (g, h) \) satisfies the Killing condition, we can represent \( h \) as a sum of symmetrized tensor products of infinitesimal isometries of \( g \). Assuming this, let us consider the above three cases separately.

**Case (7.2):** Checking the Killing condition for the pair \( (\tilde{g}, h) \) we obtain that \( h \) must be a linear combination of \( g \) and \( \tilde{g} \). This means that our operator is essentially two-dimensional.

**Case (7.3):** Checking the Killing condition for the pair \( (\tilde{g}, h) \) we obtain \( h = c_1 g + c_2 \tilde{g} + h_0 \) where

\[
h_0 = \begin{pmatrix}
\nu & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}.
\]

35
One can verify that this ansatz for $h$ satisfies all other conditions.

**Case (7.4):** In this case, it is no longer sufficient to consider the Killing condition alone: we also need the linearity of $h$ with respect to $\tilde{g}$, that is $\nabla^2 h = 0$, where $\nabla$ corresponds to $\tilde{g}$. These conditions imply $h = c_1 g + c_2 \tilde{g} + h_0$, where

$$h_0 = \begin{pmatrix} 0 & \mu & 0 \\ \mu & 0 & 0 \\ 0 & 0 & \nu \end{pmatrix}.$$ 

One can verify that this ansatz for $h$ satisfies all other conditions.

It remains to note that all constants appearing in the classification can be eliminated by linear transformations of $x, y, z$, leading to the normal forms as stated in Theorem 5.

If one does not allow linear changes of the independent variables $x, y, z$, the analogue of Theorem 5 reads as follows

**Theorem 12.** Any non-degenerate three-component Hamiltonian operator in 3D, which is not transformable to constant coefficients, can be brought by a transformation of the dependent variables $u^i$ to

$$P^{ij} = g^{ij} \frac{d}{dx} + \tilde{g}^{ij} \frac{d}{dy} + (c_1 g^{ij} + c_2 \tilde{g}^{ij} + h_0^{ij}) \frac{d}{dz} + \tilde{b}^{ij}_k (u^k + c_2 u^k),$$

where $c_1, c_2$ are constants, $\tilde{b}^{ij}_k$ are the contravariant Christoffel symbols of $\tilde{g}$, and the contravariant metrics $g, \tilde{g}, h_0$ assume one of the two canonical forms

- **form 1:**
  $$g = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad \tilde{g} = \begin{pmatrix} -2 u^1 & -\frac{1}{2} u^2 & u^3 \\ -\frac{1}{2} u^2 & u^3 & 0 \\ u^3 & 0 & 0 \end{pmatrix}, \quad h_0 = \begin{pmatrix} \nu & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$
  here $\nu = \text{const};$

- **form 2:**
  $$g = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \tilde{g} = \begin{pmatrix} -2 u^1 & u^2 & 0 \\ u^2 & 0 & 0 \\ 0 & 0 & \lambda \end{pmatrix}, \quad h_0 = \begin{pmatrix} 0 & \mu & 0 \\ \mu & 0 & 0 \\ 0 & 0 & \nu \end{pmatrix},$$
  here $\lambda, \mu, \nu$ are constants.

It follows from the proof of Theorem 5 that any non-degenerate three-component Hamiltonian operator in 4D is essentially 3D, or can be transformed to constant coefficient form. We point out that there exists non-trivial examples of Hamiltonian operators in any dimension:
Example. The following expression provides an example of non-constant irreducible $N$-component Hamiltonian operator in $N$ dimensions:

$$
P^{ij} = \eta^{ij} \frac{d}{dx^1} + g^{ij} \frac{d}{dx^2} + b^{ij}_k u^k_x + \sum_{m=1}^{N-2} h^{ijm}_m \frac{d}{dx^{m+2}},
$$

where

- $\eta$ is the constant $N \times N$ anti-diagonal bivector: $\eta^{ij} = \delta^{i,N+1-j}$;
- the bivector $g$ is defined as $g^{ij} = \mu^{(N;N-2)} + g^{ij}_0$, where $\mu^{(N;N-2)}$ is defined by (6.1), namely
  $$
  \mu^{(N;N-2)ij} = [3(i + j) - 8] u^{i+j+N-3},
  $$
  and $g^{ij}_0 = \delta^{i,N-j} + \lambda \delta^{i,N+1-j}$;
- $b^{ij}_k$ are the contravariant Christoffel symbols of $g$, namely
  $$
  b^{11}_{N-1} = -1, \quad b^{12}_N = 2, \quad b^{21}_N = -1,
  $$
  with all remaining coefficients equal to 0;
- the $N - 2$ constant bivectors $h^m$ are defined as $h^{ijm} = \delta^{im} \delta^j_m$.

For $N = 3$, this example corresponds to the first case of Theorem 5.

8 Concluding remarks

This paper outlines an approach to the classification of first-order multi-dimensional Hamiltonian operators of differential-geometric type. Our main contributions include a complete list of 2D Hamiltonian operators with three and four components, as well as the classification of multi-component operators in case where the corresponding affinor consists of Jordan blocks with distinct eigenvalues.

1. Our calculations demonstrate that the most challenging case is the one where the Jordan normal form of the affinor $L = \tilde{g} g^{-1}$ consists of several Jordan blocks with the same eigenvalue. To complete the classification, one needs to understand the structure of such operators: due to the splitting lemma, the general Hamiltonian operator would be representable as their direct sum.

2. Given any 2D Hamiltonian operator from our list, it would be interesting to classify Hamiltonians that generate integrable $2 + 1$ dimensional systems of hydrodynamic type. The existing results suggest that ‘integrable’ Hamiltonians form finite-dimensional moduli spaces, and are quite non-trivial even for constant-coefficient operators, see [11, 12, 13] for the first steps in this direction.
3. It would be interesting to develop a deformation theory of 2D Hamiltonian operators in the spirit of [14, 4, 9], and to investigate triviality of Poisson cohomogy in 2D. Some results in this direction were recently obtained in [3].
