1  
2  
3 Serious infection affects around 20% of patients who present febrile and neutropenic<sup>1</sup>. Febrile  
4 neutropenia is thus a well-recognised medical emergency. Addressing the challenges of both rapid  
5 delivery of antibiotics to patients at risk of life-threatening sepsis, as well as appropriate antibiotic  
6 stewardship to reduce antibiotic overuse, continue to keep this a priority for clinicians, patients and  
7 parents. Audits of febrile neutropenia (FN) practice have previously demonstrated variation in  
8 definitions for FN and its management<sup>1,2</sup>. In September 2012, the National Institute for Clinical  
9 Excellence (NICE) published the 'Neutropenic sepsis: prevention and management of neutropenic  
10 sepsis in cancer patients'<sup>3</sup> guideline and we sought to assess if this has reduced variations in practice.

11  
12  
13 This re-audit included 45 UK centres (14 CCLG principal treatment centres). The centres completed  
14 questionnaires regarding their febrile neutropenia policy and any admissions over a 2 week period in  
15 March 2015. 108 episodes from 30 centres were recorded ranging from 0-10 episodes per centre.

16  
17  
18 The results show continued variability in definition and management. The NICE suggested definition  
19 of FN (temperatures > 38 °C and neutrophil count of <0.5) is used by 21/43 (49%) centres (see table  
20 1). Only 19/45 (42%) centres use risk stratification at admission (a modified Alexander approach in  
21 16 centres, as suggested by NICE, with one centre using the SPOG model<sup>4</sup> and two setting up their  
22 own stratification system).

23  
24 The NICE guideline suggests patients presenting with FN should have central and peripheral blood  
25 cultures and blood tests including CRP and lactate. Central blood cultures were sent in over 90% of  
26 episodes and 19% of episodes had peripheral blood cultures performed but only two centres routinely  
27 performed paired blood cultures. CRP was analysed in 83% of episodes but lactate in only 15% of  
28 admissions with 6 centres routinely testing lactate on presentation.

29  
30  
31 37% centres use single agent piperacillin/tazobactam as initial antibiotic treatment, 34% use  
32 piperacillin/tazobactam with an aminoglycoside and 13% meropenem alone. Overall, 62% of  
33 inpatients received their antibiotics within 60 minutes of admission or febrile episode. 9 of 17 centres  
34 with multiple admissions over the 2 week period administered the first dose of antibiotic within 60  
35 minutes in ≥ 80% of occasions.

36  
37  
38 44 (40%) episodes were assessed as low risk at 48hrs with 28 (64%) switching to oral antibiotics and  
39 16 (36%) continuing IV therapy. Antibiotics were stopped upon resolution of fever irrespective of  
40 neutrophil count in 75%, whilst 14% appropriately continued antibiotics to treat a confirmed  
41 infection. In 11% of episodes the reason for continuation of antibiotics was unclear.

42  
43 The results show continuing variation in practice and a lack of adherence to NICE guidance. The  
44 variance has not significantly changed since the previous audit in 2012. Participating centres have  
45 been sent the results plus centre specific analysis to see their results in comparison to national practice  
46 and guidelines. A re-audit is planned for 2016. The adoption of a national policy on neutropenic  
47 sepsis management based on the best available evidence of clinical effectiveness and cost-  
48 effectiveness requires local implementation but should improve outcomes.
