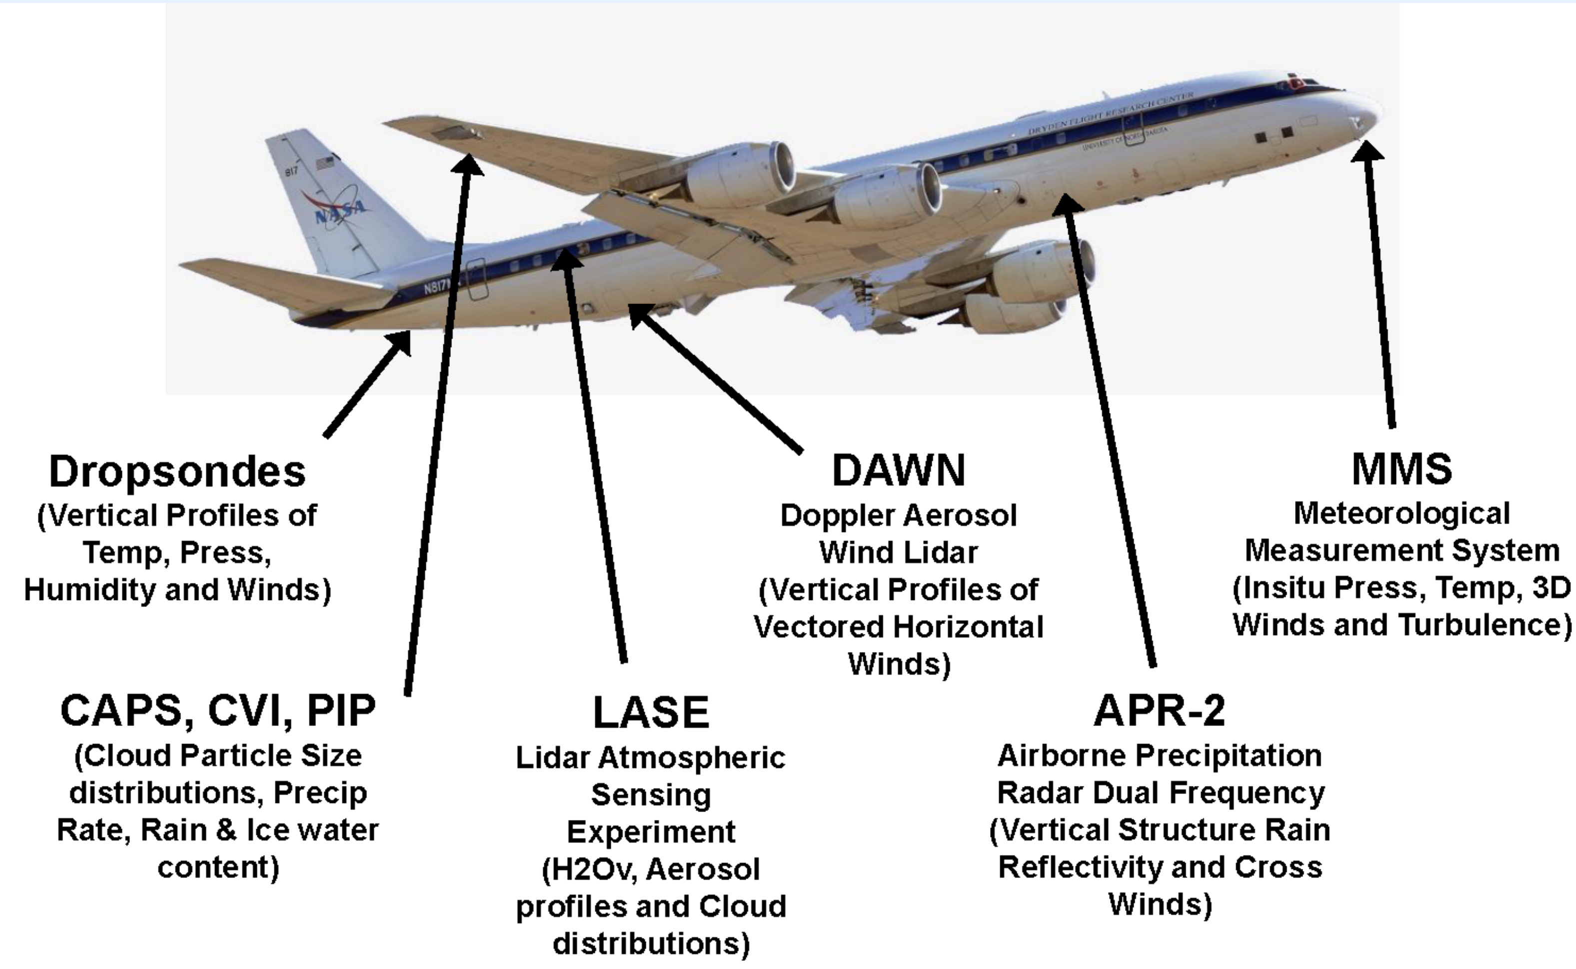
GRIP DC-8 Payload

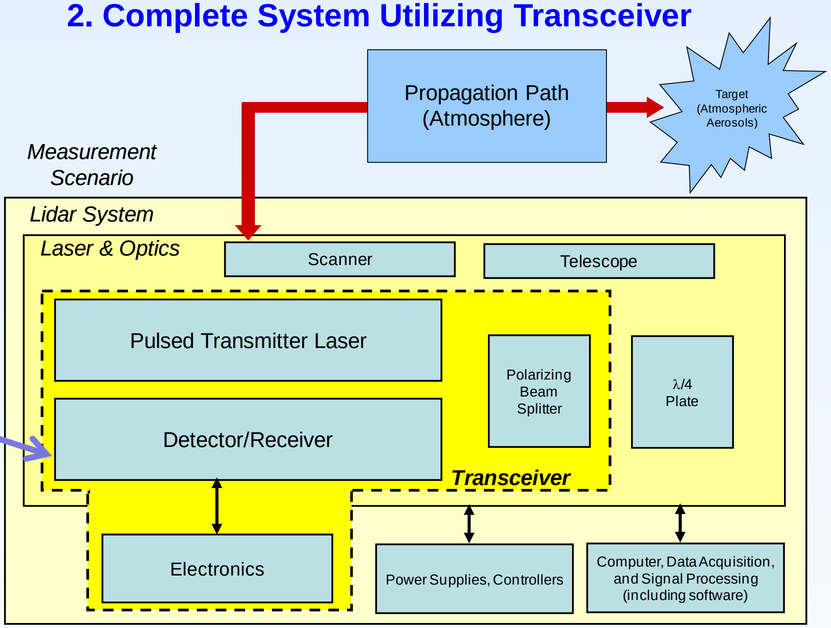


Genesis and Rapid Intensification Process (GRIP) Campaign
Coherent Pulsed Doppler Wind Profiling Lidar System

1. World's Most Capable Transceiver
Packaged, Compact, Robust

0.25 J pulse energy, 10 Hz PRF
15 cm receiver optical diameter, 34 kg (75 lbs.)
15.2 x 29.5 x 67.3 cm (6 x 11.6 x 26.5 inches)

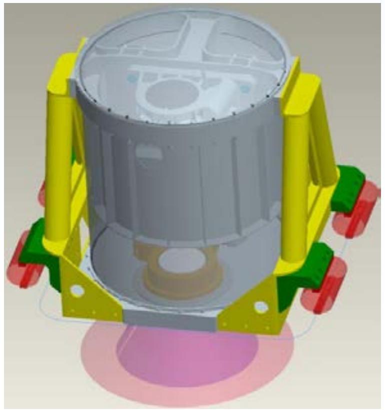
2. Complete System Utilizing Transceiver



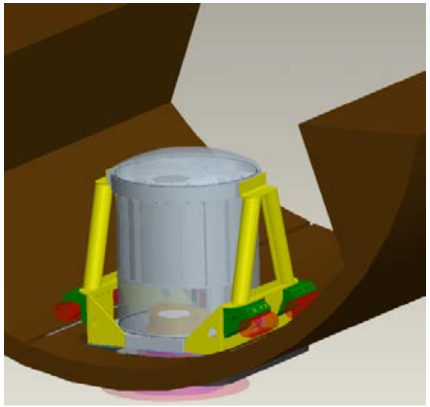
3. Ground-based Wind Measurement Performance

- RMS wind difference from balloon sonde, 0 – 6 km altitude, = 1.1 m/s and 5.8°
- No alignment needed after interstate travel in trailer
- Overnight unattended operation
- Vertical winds to 11 km altitude
- Horizontal vector winds to 7 km altitude
- Data processing choice of multiple values of vertical and horizontal resolution
- Same technology as anticipated space mission

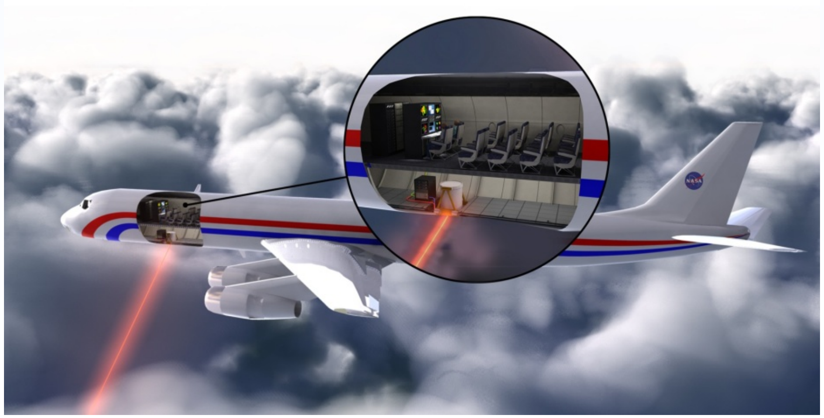
4. Enclosure for All Lidar Optics
Robust Aircraft Design



5. Optics in DC-8

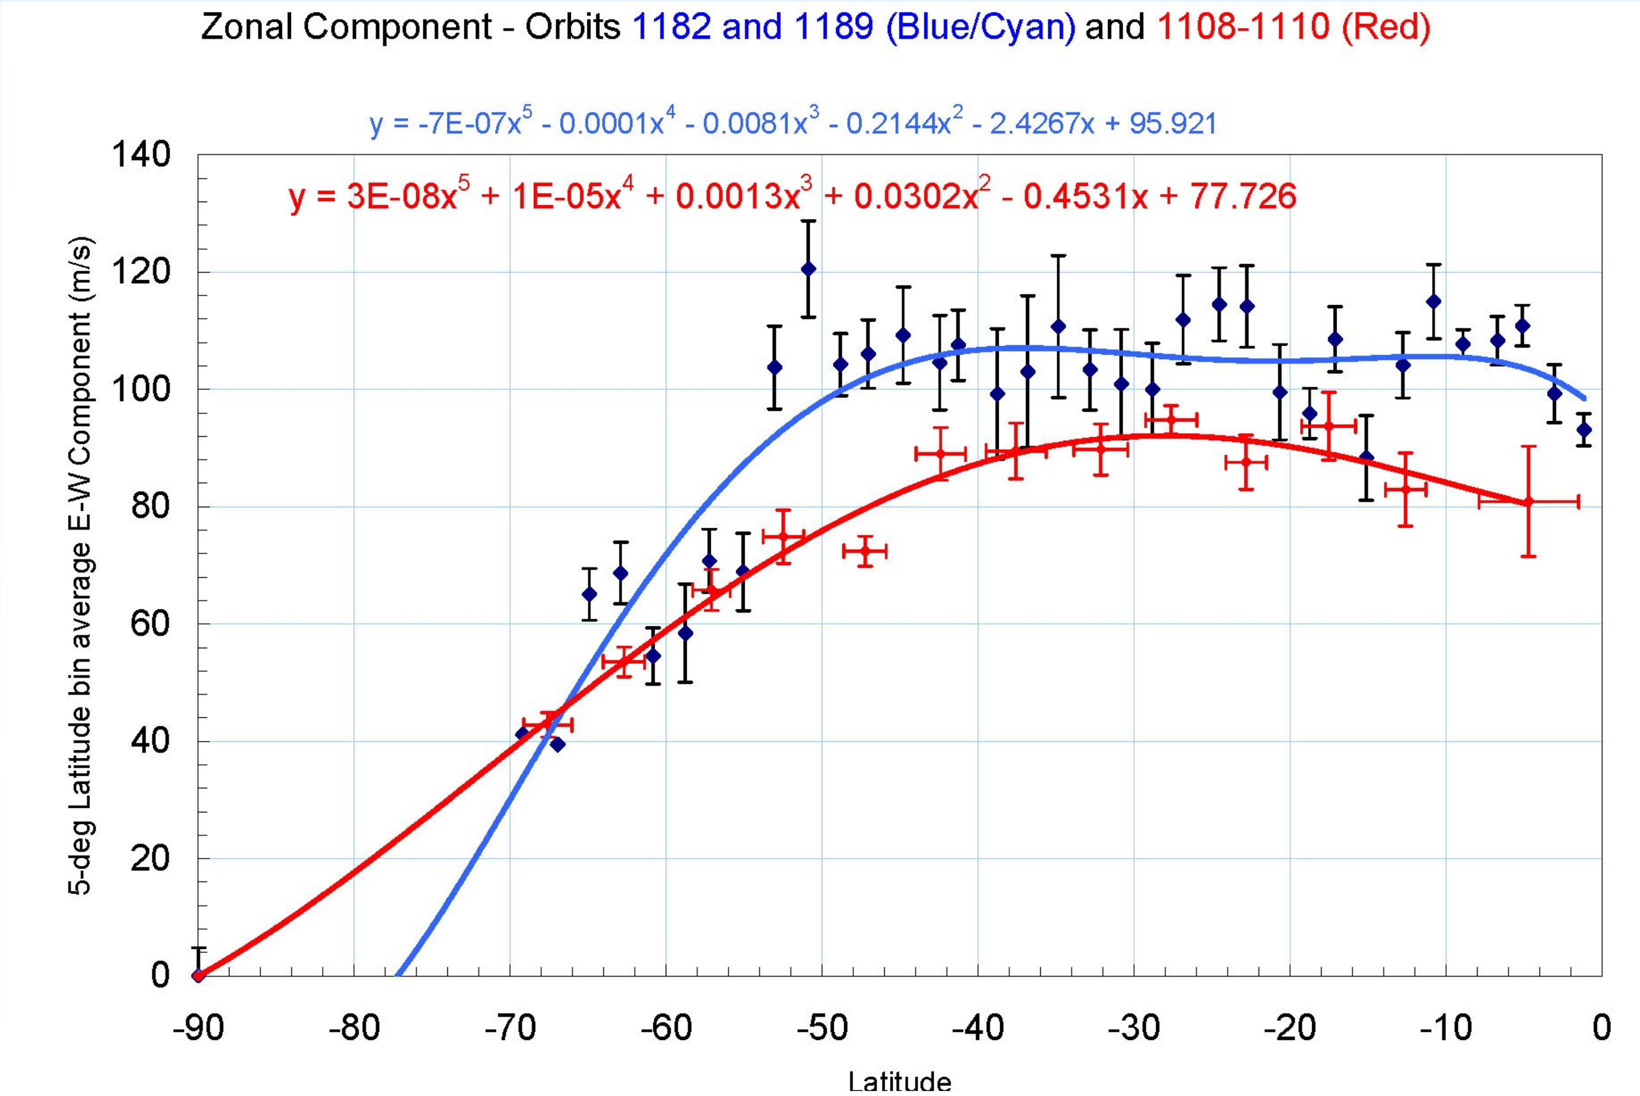


6. Lidar System in DC-8



Need for Doppler Wind Measurements on Venus

- Global super-rotation is a puzzle
- Keys to understanding the circulation are spatially distributed measurements at the same vertical level to enable estimates of eddy and mean contributions to transport of angular momentum meridionally
- Cloud motions provide only day side winds with high spatial resolution
- Night side cloud tracking measurements refer to a different level
- Hence the true zonal average circulation is not well known



Zonal Component - Orbits 1182 and 1189 (Blue/Cyan) and 1108-1110 (Red)
y = -7E-07x5 - 0.0001x4 - 0.0081x3 - 0.2144x2 - 2.4267x + 95.921
y = 3E-08x5 + 1E-05x4 + 0.0013x3 + 0.0302x2 - 0.4531x + 77.726

Objectives

- Obtain direct measurement of Venus winds within the upper cloud layer and the overlying aerosol (haze) layer
- Obtain directly measured heights of cloud tops and their optical depths
- Obtain aerosol concentration and distribution within the upper haze layer

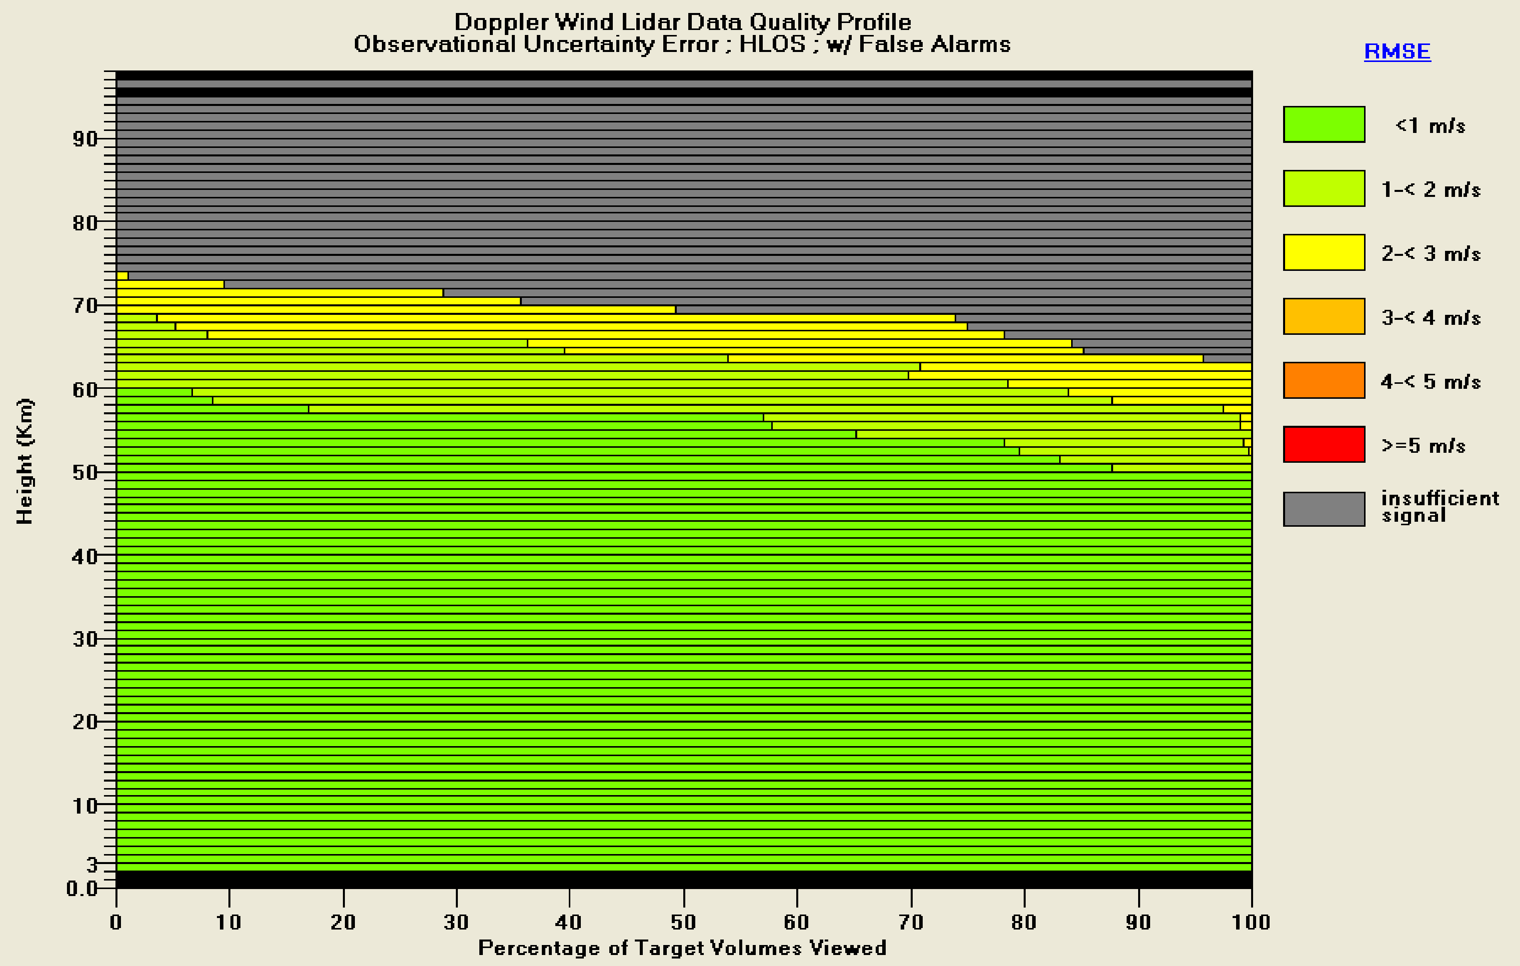
Proposed Approach

- The thick uniform cloud cover (1 micron radius and sub-micron sized haze particles in polar latitudes) should enable good Doppler measurements and provide height resolved results of atmospheric motions
- Use an orbiting Doppler lidar to obtain u, v, w components of the winds (clouds and aerosols permitting).
- Design instrument for 1km vertical resolution and 200 km horizontal spacing of profiles; enable on-orbit changes to integration and sampling strategies.
- Operate full or partial orbits depending upon platform power availability

Initial Considerations

- Build upon the NASA funded Mars Lidar Simulation Model (MLSM) developed by Simpson Weather Associates.
- Modify as needed to represent Venus conditions; preference is to use a community Venus weather model.
- Assume similarities in cloud reflectance at 2 μm and spherical particles in the haze layer.

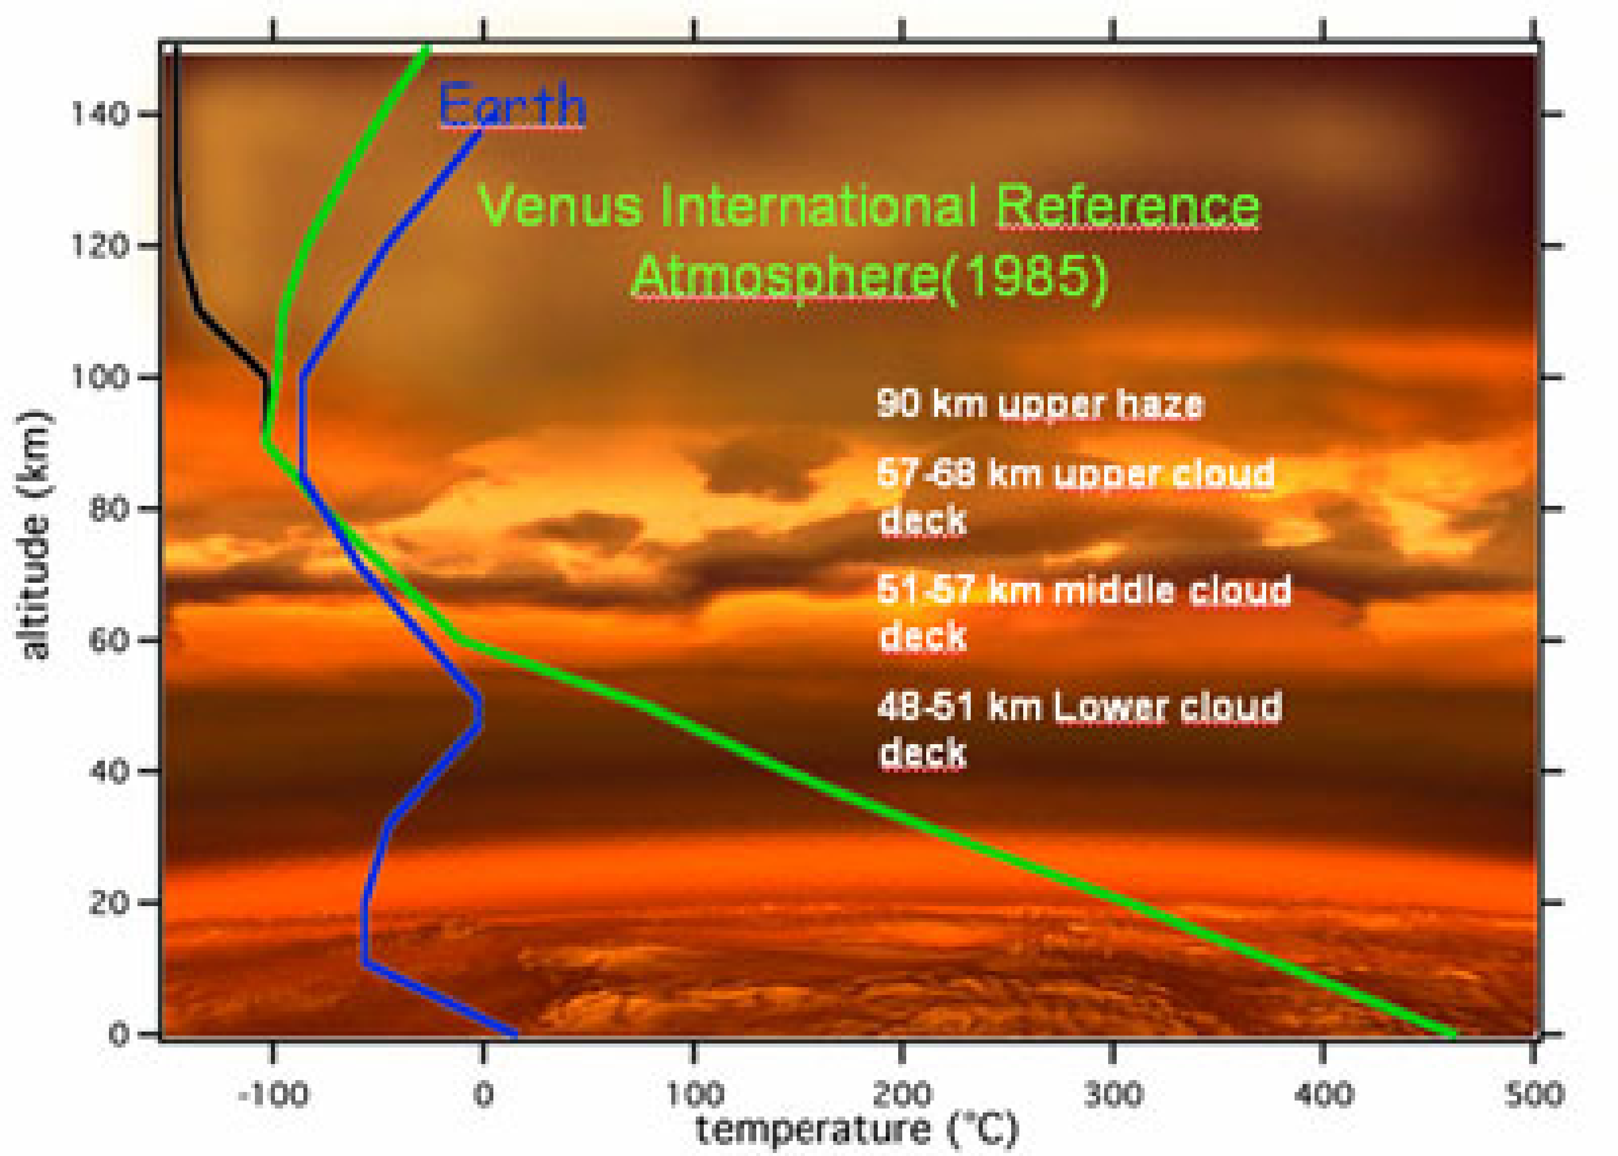
Doppler Wind Lidar Profile Simulation on Mars (Example)



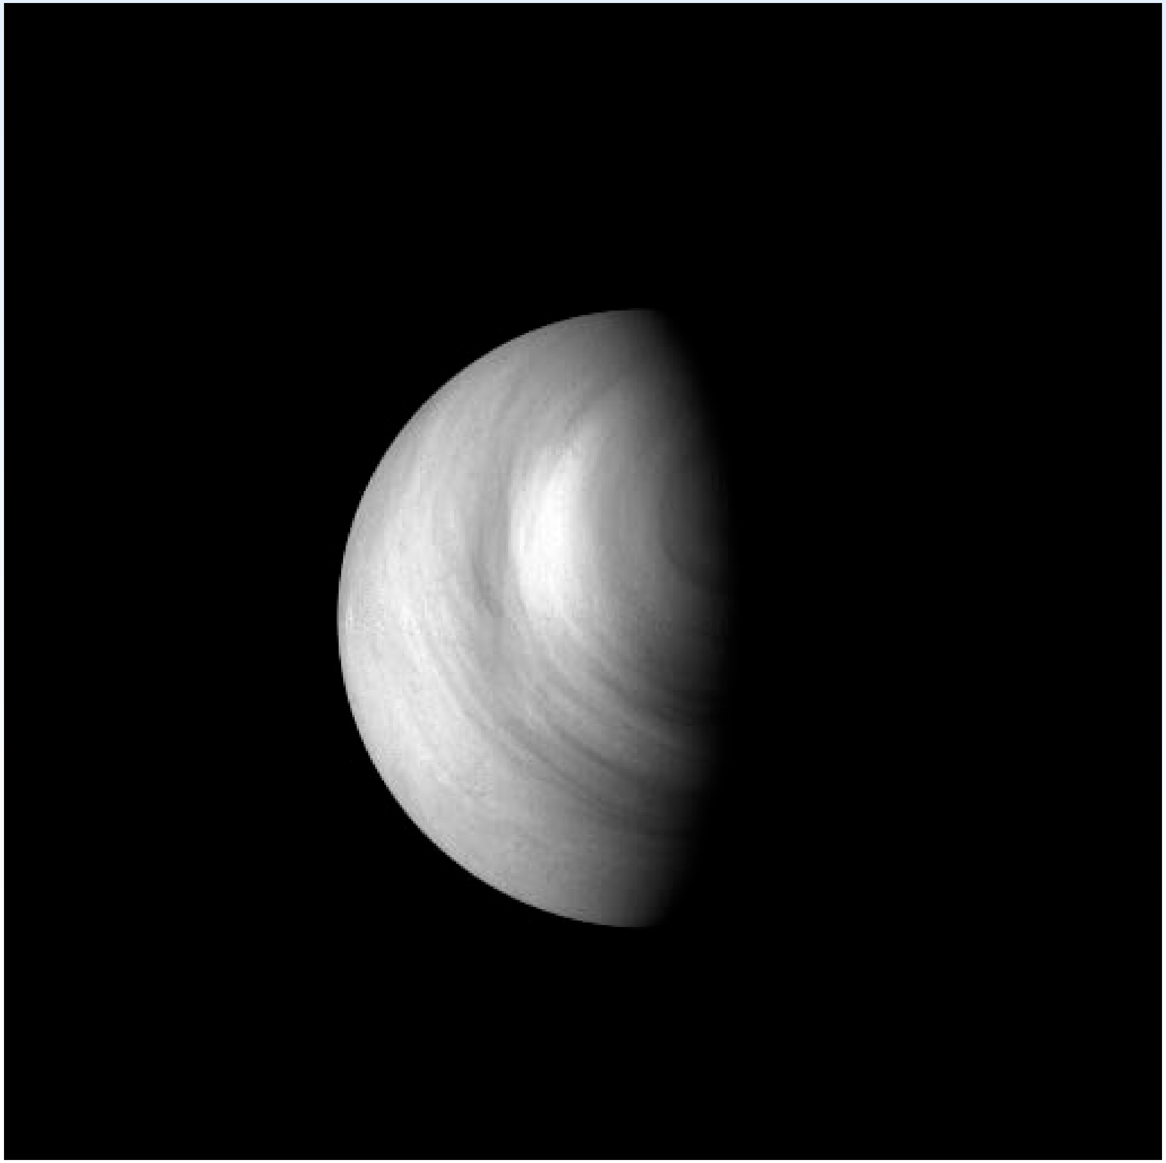
RUN: MCD Ls=0 deg 2001Z (2 hr sim.) Global
ALTITUDE: 400 Km ORBIT INC: 98 deg
TARGET ATM.: median Backscatter, R= 0.30, constant Q
ELEVATED DUST: user defined R = 0.00 um

DETECTION: DWL SCAN: 4 pt. Step/Stare
WAVELENGTH: 2.053472 um NADIR: 45. deg
ENERGY: 0.25 J APERTURE: 0.5 m PLT PWR: 63 W
PRF: 10. Hz ACCUM. TIME: 25 s BETA THR.: 50.%

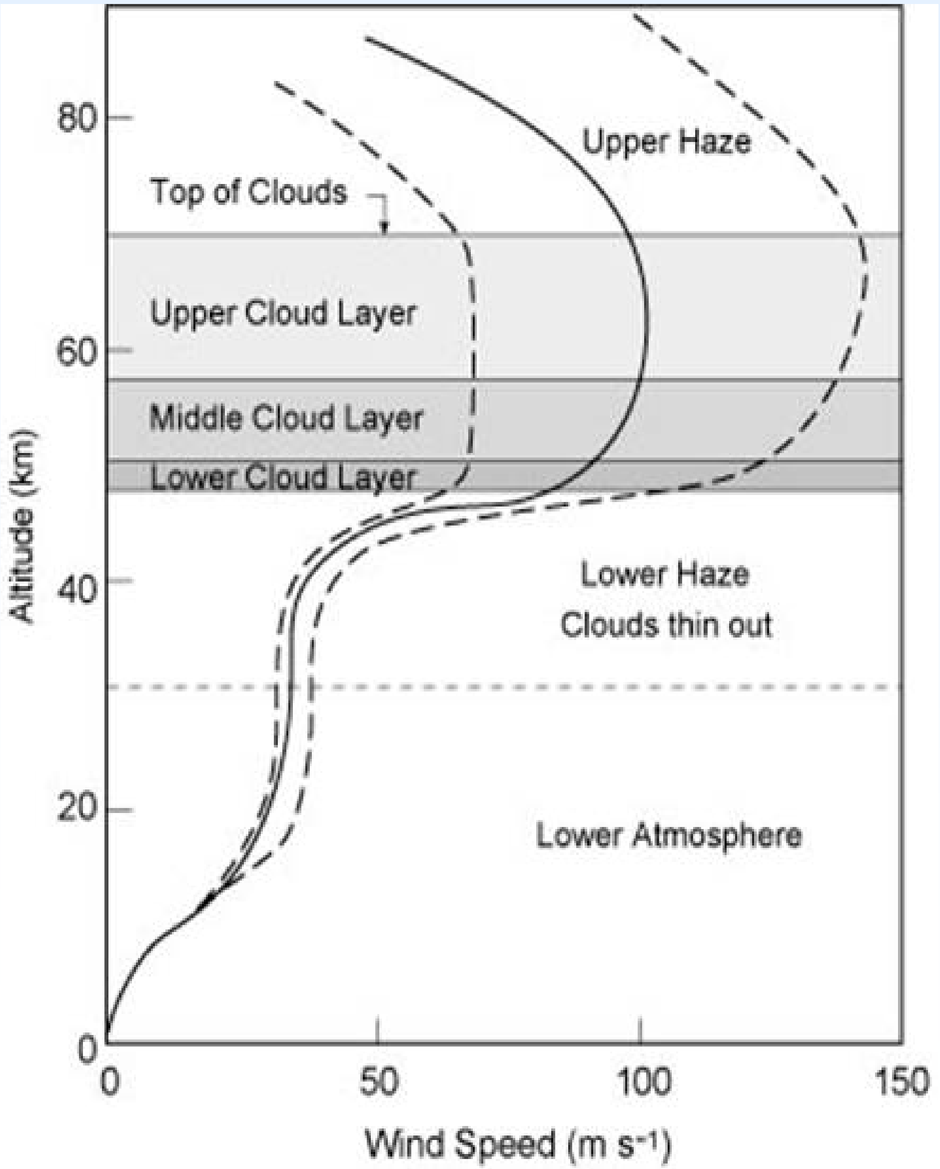
Venus International Reference Atmosphere



Venus Cloud Layers



Target Region for VenWinds



VenWinds Instrument

Wavelength (μm)	2.0	
Energy per pulse (J)	0.001	
Pulse length (nsec)	180	
PRF (Hz)	500	
Optical output (watts)	0.5	
Wallplug power (watts)	10	Includes cooling but not data collection/transmission
Telescope diameter (m)	0.1	
Scanner (step stare 4 azimuth angles plus 1 nadir)		Other beam director options can be considered
Nadir scanning angle (degrees)	20	Can be varied
Dwell time (seconds)	10	This would result in 5000 samples being integrated for one LOS wind component.
Sample volume diameter (m)	0.1	
Sample volume length; range gate (m)	1100	The number of pulse lengths in this volume
Beta50 (msr-1)	6.4×10^{-7}	Backscatter for Venus clouds ~ 1.0×10^{-5}
Weight (kg)	15 -50	Depends on effort to reduce weight of current technology
Dimensions (l x w x h)	TBD	

VenWinds Data

Height resolution(m) (average wind in layer)	1000	
Horizontal spacing between wind profiles (u, v, w) (km)	200	This can be changed to be as small as 25km with no sacrifice on accuracy, just sensitivity.
LOS velocity precision (m/s)	< 1	
Maximum horizontal wind (m/s)	200	
Aerosol profiles (m) (layer average during scan)	1000	Each LOS observation yields a wind speed, turbulence estimate (TKE) and signal intensity
Number of profiles per orbit	100 - 1000	Varies with integration time
Vertical coverage	TBD	Minimum of cloud top speeds and heights
Cloud top range resolution (m)	~ 100 meters	

Summary

- NASA Langley Research Center is the world leader in developing pulsed 2-micron coherent Doppler/DIAL/backscatter lidar for space remote sensing of Earth's atmosphere and have successfully developed and matured the DWL technologies and techniques
- These technologies can be customized and matured for Venus through leveraging the knowledge and knowhow acquired by the LaRC team in last two decades
- Simpson Weather Associates and NASA LaRC have jointly developed a Mars Lidar Simulation Model to test DWL concepts for a Mars mission and it can be used for Venus wind simulation
- Based upon general available information regarding the atmosphere of Venus, a small Doppler Wind Lidar (DWL) could provide wind, cloud and aerosol information from an orbit of several 100 kms above the surface of Venus.
- Issues of power, weight, volume need to be addressed to identify the tall poles in this proposed instrument.
