Uncertainties in cloud feedback remain in GCMs

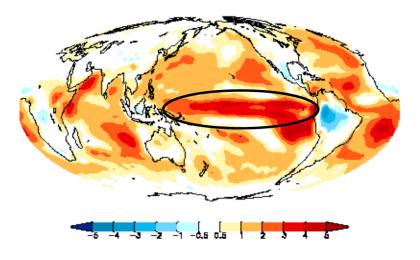

Local contribution to intermodel spread in cloud feedback: AR4

· Most of intermodel spread arises from low stratocumulus/cumululs regions

Soden and Vecchi (2011

Local contribution to intermodel spread in cloud feedback: AR5

• Low subtropical clouds still uncertain.

Large contribution from equatorial Pacific.

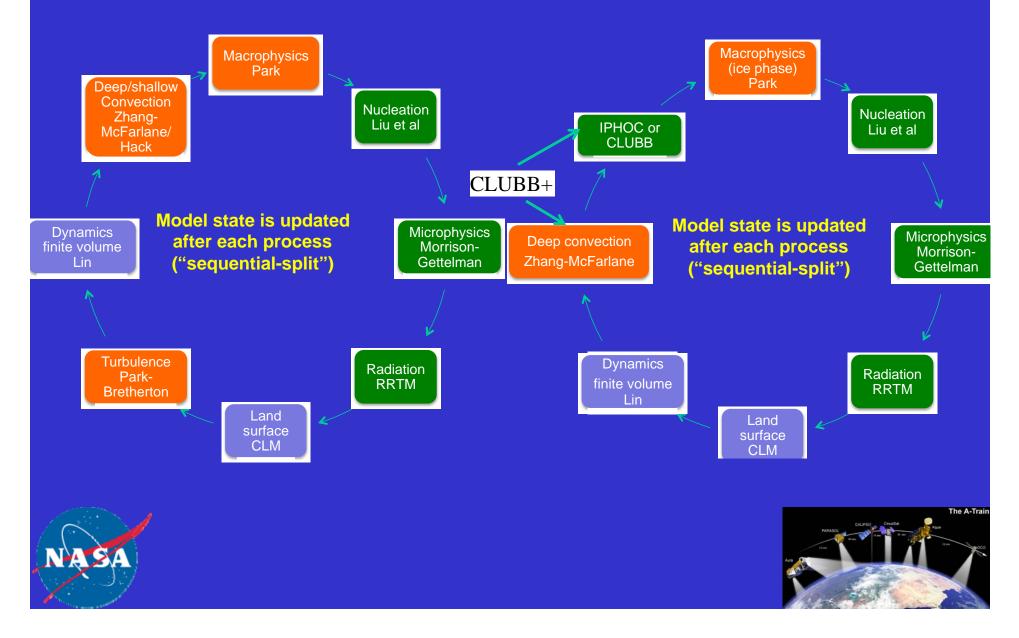

The A-Trai

Soden and Vecchi (2011):

 Low cloud cover is responsible for ~3/4 of the difference in global-mean net cloud feedback among AR4 models, with the largest contributions associated with low-level subtropical marine cloud systems;

The low-cloud inconsistency and deficiency in most of the models.

CAM5, CAM5 (IPHOC; CLUBB), and AM3 (CLUBB, CLUBB+)

The higher-order turbulence closure approach

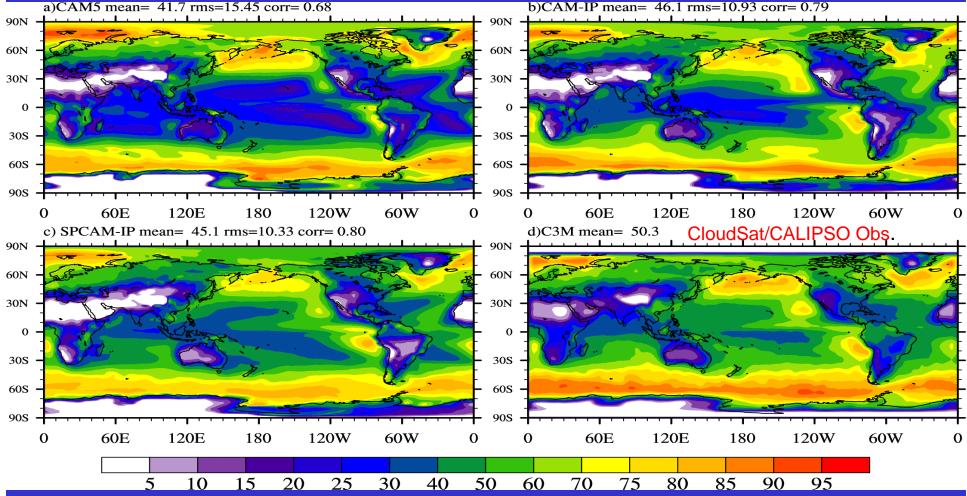

Differences between IPHOC and CLUBB used in GCMs?

CLUBB (Cloud Layers Unified by Binormals; Golaz *et al.* 2002); IPHOC (Intermediately Prognostic Higher-order turbulence Closure; Cheng and Xu 2008)

| | / | |
|--------------------------------|---------------------------------|---------------------------|
| | IPHOC | CLUBB |
| Third-order moments | 3 | 1 |
| Known moments (predicted) | 12 (5 in GCM; 12 in CRM) | 10 (10 in GCM and CRM) |
| Double Gaussian | Analytical II | Analytical I |
| Convergence of double Gaussian | To a single Gaussian if sk=0 | not |
| PBL height | Predicted | n/a |
| | G(q _t) | q_t |

Tuned parameter tests in CAM5-CLUBB (Guo *et al.* 2015)

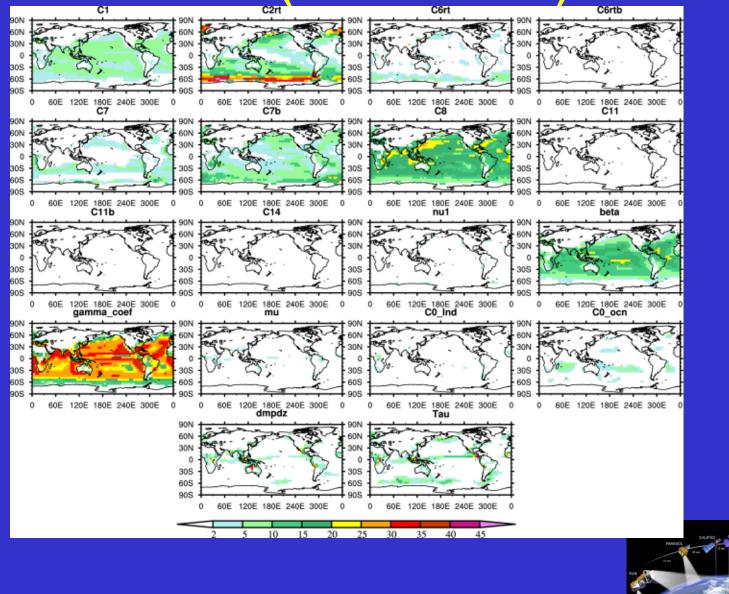

Table 1. Tunable Parameters of CLUBB and ZM

| Parameter | Description | Default Value | Investigated Range |
|----------------|---|-------------------|-------------------------------|
| C1 | Constant associated with $w^{\prime 2}$ dissipation | 2.5 | 1.25–5 |
| C2rt | Constant associated with $q_t'^2$ dissipation | 1.0 | 0.5-2 |
| C6rt | Low skewness of Newtonian damping of water flux | 4.0 | 3.0-8.0 |
| C6rtb | High skewness of Newtonian damping of water flux | 6.0 | 3.0-8.0 |
| C7 | Low skewness of buoyancy damping of water flux | 0.8 | 0.25-1.0 |
| C7b | High skewness of buoyancy damping of water flux | 0.65 | 0.25-1.0 |
| C8 | Constant associated with Newtonian damping of $\overline{w'^3}$ | 3.0 | 1.5-6.0 |
| C11 | Low skewness of buoyancy damping of $w^{'3}$ | 0.8 | 0.0-1.0 |
| C11b | High skewness of buoyancy damping of $w^{'3}$ | 0.65 | 0.0-1.0 |
| C14 | Constant of Newtonian damping of u^{2} and v^{2} | 1.0 | 1.0-2.0 |
| v (nu) | Background coefficient of eddy diffusion | 20.0 | 10.0-40.0 |
| β (beta) | Constant related to skewness of θ_{I} and q_{t} | 1.75 | 0.0-3.0 |
| γ (gamma_coef) | Constant of the width of PDF in w-coordinate ($\tilde{\sigma}_{w}^{2}$) | 0.32 | 0.1-0.6 |
| μ (mu) | Parcel entrainment rate (1/m) | 0.001 | $0.5 - 2.0 	imes 10^{-3}$ |
| C0_Ind | ZM precipitation efficiency over land | 0.0059 | 0.003-0.09 |
| C0_ocn | ZM precipitation efficiency over ocean | 0.045 | 0.003-0.09 |
| dmpdz | Entrainment rate of ZM | -10 ⁻³ | -0.2 to -2×10^{-3} |
| tau | CAPE consumption time scale (s) | 3600 s | 1800-10,800 |

Sensitivity to Tuning parameter tests in CAM5-CLUBB (Guo et al. 2015)

The A-Train

Summary and conclusions

- The higher-order turbulence closure approach offers a promising approach to subgrid-scale variability.
- The low-level clouds are improved in different GCM simulations and the biass in SW cloud radiative forcing are reduced.
- The potential for realistic simulation of cloud processes is great with the higher-order turbulence closure approach, for example, coupling with cloud microphysics, and unified low and deep convection parameterization.
- Sensitivity to parameters are especially strong for skewness-related parameters. A better constraint is needed from global observations.
