(57) **ABSTRACT**

Described herein are systems and techniques for a motion capture system and a three-dimensional (3D) tracking system used to record body position and/or movements/motions and using the data to measure skin strain (a strain field) all along the body while a joint is in motion (dynamic) as well as in a fixed position (static). The data and technique can be used to quantify strains, calculate 3D contours, and derive patterns believed to reveal skin's properties during natural motions.

FIG. 7

SYSTEM AND METHOD FOR MEASURING SKIN MOVEMENT AND STRAIN AND RELATED TECHNIQUES

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH

This invention was made with government support under Grant No. CNS0932015 awarded by the National Science Foundation and under Grant Nos. NAS5-03110 and NAS5-98051 awarded by NASA. The government has certain rights in this invention.

CROSS REFERENCE TO RELATED APPLICATIONS

Not Applicable.

FIELD OF THE INVENTION

The concepts described herein relate to a system and technique for measuring and modeling skin movement and more particularly to a system and technique for quantifying skin movement and deriving strain fields, contours and three-dimensional patterns.

BACKGROUND OF THE INVENTION

As is known in the art, while there is extensive understanding of human skin properties based on active tensile testing, both in vitro and in vivo, there is little current knowledge of the strains experienced by skin during natural movements.

Understanding the skin's material properties and natural motion is important to help provide better understanding in a number of areas including: creating tissue engineering scaffolds that integrate smoothly with little scarring; understanding skin growth; aging; and changes due to diseases. Past work has been completed to ascertain material property data of isolated skin samples with in vitro tensile testing and by applying external loads (pulling, twisting, indenting, and suctioning) and measuring the resulting deformations in vivo. These experimental methods are limited because the skin behaves differently when removed from surrounding tissues in vitro and in vivo techniques do not take into account the skin's biaxial prestress. Because of the anisotropic behavior, it has been theorized that the skin contains lines of non-extension (LONEs), or contours of the skin that stay a constant length with minimal stretching capacity that only rotate during joint motion. As the body moves, particularly close to the joint, these LONEs do not always exist; in those cases the contours that are most important are those with the minimum extension or compression. Previous work, however, have only been able to qualitatively find non-extending lines.

SUMMARY OF THE INVENTION

The concepts, systems and techniques described herein result in a new understanding of the relationship between the structure of skin and the strains it experiences during natural joint movement. In particular, concepts, systems and techniques allow one to quantify strains, calculate three-dimensional (3D) contours, identify lines of non-extension (LONEs) and derive patterns that are believed to reveal skin's properties during natural motions. The system and techniques described herein may thus find application in a wide variety of areas including, but not limited to, design of tissue-engineering scaffolds, medical diagnosis for skin surgery, the design

and development of soft exoskeletons, as well as commercial spacesuits and athletic garments.

In accordance with the concepts, systems and techniques described herein, a motion capture system (including a camera, video acquisition, processing and tracking markers) and a three-dimensional (3D) tracking system (e.g. a laser scanner) are used to record body movements/motions. By recording body movements/motions a new method is provided for measuring the skin's strain all along the body (a strain field) while a joint is in motion (dynamic) as well as in a fixed position (static). Thus, while prior art techniques were able to qualitatively find non-extending lines, having dynamic information during the entire motion, allows one to quantify strains, calculate 3D contours, and derive patterns that are believed to reveal skin's properties during natural motions.

From motion capture or laser scan position data, a lines of non-extension (LONEs) processor **522** calculates lines of non-extension by analyzing the changes in distance between each marker point and its closest neighbors from initial position to deformation, and calculating strain values. When a rectangular grid (such as that shown in FIGS. **3A**, **3B** is used), closest neighbors are considered to be the two markers adjacent in the same row and also the three markers in the rows above and below in the corresponding columns. In one embodiment, second order Lagrangian strains ϵ are calculated using the following equation (it should be noted that the second order equation is used because the strains are so large):

$$\varepsilon = \frac{l^2 - l_0^2}{2l_0^2} = \frac{\Delta l}{l_0} + \frac{(\Delta l)^2}{2l_0^2};$$

In which:

l is the new distance between two points

l_o is the original length between two points, and

Δl is the difference between the two.

The 3D strains surrounding each data point are projected onto a two-dimensional (2D) plane tangent to the body skin at each marker position. In one exemplary embodiment, this 2D plane is created by first averaging the normal vectors to the planes between each neighboring pair of strain vectors. This new "average" normal of (eight) 8 different planes defines the normal vector to the tangential plane created at the marker position. It should be appreciated that other techniques to compute the plane, may also be used. After being projected onto the tangential plane, the strains are then rotated in pairs onto the axes defined by the location of the marker directly above and then averaged together to give the longitudinal strain (ϵ_y), the circumferential strain (ϵ_x), and the shear strain (ϵ_{xy}).

This is followed by eigenvector analysis to determine the principle strains (ϵ_I and ϵ_{II}). If the principle strains are of opposite signs, meaning there is both extension and compression, they are used to mathematically determine the angle of the lines of non-extension ($\square$) with the known equations:

$$\tan^2\phi = \frac{\varepsilon_I(2 + \varepsilon_I)}{-\varepsilon_{II}(2 + \varepsilon_{II})} \quad \tan^2\phi = \frac{(1 - \varepsilon_I)^2(\varepsilon_I(2 + \varepsilon_I))}{(1 + \varepsilon_{II})^2(1 - (1 + \varepsilon_{II})^2)}$$

where the first equation is the angle between the primary eigenvector and the line of non-extension projected onto the initial position and the second equation is the same angle projected onto the deformed position. If the principle strains

3

are of the same sign, meaning there is only local extension or local compression, then the minimum extension or minimum compression is recorded, respectively. These angles are projected onto the body surface (e.g., leg) and, during primarily stationary analysis only, they are connected to continuous lines (e.g. using basic spline functions). This method of finding tangent planes and creating strain tensors requires all eight (8) surrounding points. Other techniques may, of course, also be used.

With this particular methodology, body motion and skin movement are provided and skin-strain field analysis and patterning/contours are provided. In one embodiment, the motion capture system measures skin movement and strain around the knee during a squatting motion. It should, of course, be appreciated that the system and techniques described herein above are not limited to use with any particular body part (e.g. knee regions) or any particular motion (e.g. squatting), rather the system and techniques described herein may be used in any body region and for any body movement including body joint movements for dynamic motions (e.g., squatting, bending, walking, etc.).

In accordance with a further aspect of the concepts described herein, a new technique to analyze skin movement and strain for a static body as well as a body in motion (e.g. around the knee during a squatting motion) includes calculations of lines of non-extension, minimum and maximum skin movement, compression and tension.

In accordance with a further aspect of the concepts, systems and techniques described herein, a method for manufacturing a garment (e.g. an athletic garment, a spacesuit, etc. . . .) comprises using a material formed into a shape by at least considering lines of non-extension of the body part over which the garment will be disposed wherein the lines of non-extension of the body part are determined, at least in part, from position data of body skin of the body part wherein the position data is generated from a plurality of position data points obtained at one or more locations defined by one or more corresponding markers disposed on the body skin wherein the position data is computed using an initial position and a deformed position and computing lines of non-extension from the position data measure at least at the initial position and a deformed position.

Thus, in accordance with a further aspect of the concepts, systems and techniques described herein, a method for design of tissue-engineering scaffolds comprises forming tissue-engineered scaffolds into a shape by at least considering lines of non-extension of the body part over which the tissue-engineered scaffolds will be disposed wherein the lines of non-extension of the body part are determined, at least in part, from position data of body skin of the body part wherein the position data is generated from a plurality of position data points obtained at one or more locations defined by one or more corresponding markers disposed on the body skin wherein the position data is computed using an initial position and a deformed position and computing lines of non-extension from the position data measure at least at the initial position and a deformed position.

Thus, in accordance with a further aspect of the concepts, systems and techniques described herein, a method for soft exoskeletons comprises forming a soft exoskeleton into a shape by at least considering lines of non-extension of the body part over which the tissue-engineered scaffolds will be disposed wherein the lines of non-extension of the body part are determined, at least in part, from position data of body skin of the body part wherein the position data is generated from a plurality of position data points obtained at one or more locations defined by one or more corresponding mark-

4

ers disposed on the body skin wherein the position data is computed using an initial position and a deformed position and computing lines of non-extension from the position data measure at least at the initial position and a deformed position.

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing features of the concepts, systems, circuits and techniques described herein may be more fully understood from the following description of the drawings in which:

FIG. 1A is a graphical representation of lines of non-extension;

FIGS. 1B-1D illustrate three (3) cases of a deformation ellipse. The circle outlined in completed (i.e. solid) lines represents to initial position and the circle with dotted lines represents the deformed position. Case 1 (FIG. 1B): LONES exist. Case 2 (FIG. 1C)—complete extension: the important direction is the line of minimum extension. Case 3 (FIG. 1D)—complete compression: the important direction is the line of minimum compression;

FIGS. 2A and 2B are a series of flow diagrams that illustrate a process for recording body positions and movements/motions for measuring skin strain along a body (a strain field) while a joint is in motion (dynamic) as well as in a fixed position (static);

FIGS. 3A and 3B illustrate exemplary placement of one hundred forty four (144) four 4 millimeter (mm) and 6 mm infrared reflecting, spherical markers on a right leg. FIG. 3A is the anterior of the leg and FIG. 3B is the posterior of the right leg;

FIGS. 4A and 4B are a graphical explanation of how strain pairs are rotated onto the new axes defined by the position of the marker directly above;

FIG. 5A illustrates a motion capture reconstruction of reflective markers on a bent leg;

FIG. 5B is a map of longitudinal strains that occur as the leg moves from extended to flexed;

FIG. 5C shows a pattern of lines of non-extension calculated from the strain field seen in FIG. 4B;

FIG. 6 is a block diagram of a system for measuring and modeling skin movement and for quantifying skin movement and deriving strain fields, contours and three-dimensional patterns; and

FIG. 7 is a block diagram of a processor of the type which may be used in the system of FIG. 6.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring now to FIG. 1A, a graphical representation of lines of non-extension includes a reference circle 10, a deformation circle 12, a line of maximum extension 14, a line of maximum contraction 16, and two lines of non-extension portions 18a, 18b of which illustrate diameters that belong to both the circle and the ellipse.

Referring now to FIGS. 1B-1D, three (3) cases of a deformation ellipse are shown. The circle outlined in completed (i.e. solid) lines 20 represents an initial position and the circle with dashed lines 22 represents a deformed position. As visible in FIG. 1B, (i.e. Case 1) lines of non-extension (LONES) exist.

Referring now to FIG. 10, as with FIG. 1B, the circle outlined in completed (i.e. solid) lines 24 represents an initial position and the circle with dashed lines 26 represents a

deformed position. As visible in FIG. 1C (i.e. Case 2—complete extension) the important direction is the line of minimum extension.

Referring now to FIG. 1D, as with FIGS. 1B and 1C, the circle outlined in completed (i.e. sold) lines **28** represents an initial position and the circle with dashed lines **29** represents a deformed position. As visible in FIG. **10** (Case 3—complete compression) the important direction is the line of minimum compression.

Referring now to FIGS. **2A** and **2B**, a process for measuring the skin's strain all along the body (a strain field) while a joint is in motion (dynamic) as well as in a fixed position (static) begins by placing markers on a body (or a portion of a body) under test to mark the points at which data will be obtained as shown in block **30**. One particular example of marker placement on a knee is described in detail below in conjunction with FIGS. **3A**, **3B**. It should, of course, be appreciated that the particular placement of markers depends upon a variety of factors including, but not limited to, the portion of the body being measured (e.g. knee, elbow, etc. . . .), and the limitations of the tracking system.

As shown in block **32**, once the markers are placed such that acceptable data can be obtained, a measurement system obtains data at each marker position. In one exemplary embodiment, the measurement system includes a motion capture system (including, for example, a camera, video acquisition, processing and tracking markers) and a three-dimensional (3D) tracking system (e.g. a laser scanner) which record body positions and movements/motions (i.e. measurement are made while the body (or body portion—e.g. joint) is in motion (dynamic) as well as in a fixed position (static). One exemplary system is described below in conjunction with FIG. **6**.

Once the data is collected, as shown in block **34**, 3D strain values are computed for each point. In one embodiment, second order Lagrangian strains ε are calculated using the following equation:

$$\varepsilon = \frac{l^2 - l_0^2}{2l_0^2} = \frac{\Delta l}{l_0} + \frac{(\Delta l)^2}{2l_0^2};$$

In which:

l is the new distance between two points
l_o is the original length between two points, and
Δl is the difference between the two.

Processing then proceeds to processing block **36** in which a two-dimensional (2D) plane tangent to the body skin at each marker position is computed. In one embodiment, the two-dimensional (2D) plane is created by first averaging the normal vectors to the planes between each neighboring pair of strain vectors. This new "average" normal of eight (8) different planes defines the normal vector to the tangential plane created at the marker position. It should be appreciated that other techniques may also be used to compute this plane. However, it is believed that this technique yields the most accurate results if a measurement system of the type described below in conjunction with FIG. **6** is used.

Once the two-dimensional (2D) plane tangent to the body skin at each marker position is computed, the 3D strains are projected onto the 2D tangent planes as shown in block **38**.

Next, as shown in blocks **40** and **42**, longitudinal strain (ϵ_y), the circumferential strain (ϵ_x), and the shear strain (ϵ_{xy}) are computed (see FIGS. **4A**, **4B**). In one embodiment, this is accomplished in the following manner. After the 3D strains are projected onto the tangential plane (processing block **38**),

the strains are then rotated in pairs onto the axes defined by the location of the marker directly above (as illustrated in FIGS. **4A** and **4B** below) and then averaged together to give the longitudinal strain (ϵ_y), the circumferential strain (ϵ_x), and the shear strain (ϵ_{xy}).

Also, as shown in processing block **44**, the principle strains (ϵ_I and ϵ_{II}) are determined. In one embodiment, this is accomplished via an eigenvector analysis to determine the principle strains (ϵ_I and ϵ_{II}).

As shown in decision block **46**, if the principle strains are of opposite signs, meaning there is both extension and compression, they are used to mathematically determine the angle of the lines of non-extension (φ) as shown in block **48**. In one embodiment this can be accomplished with the equations:

$$\tan^2\phi = \frac{\varepsilon_I(2 + \varepsilon_I)}{-\varepsilon_{II}(2 + \varepsilon_{II})} \quad \tan^2\phi = \frac{(1 - \varepsilon_I)^2(\varepsilon_I(2 + \varepsilon_I))}{(1 + \varepsilon_{II})^2(1 - (1 + \varepsilon_{II})^2)}$$

where the first equation is the angle between the primary eigenvector and the line of non-extension projected onto the initial position and the second equation is the same angle projected onto the deformed position.

Processing then flows to block **50**, in which these angles are projected onto the body surface (e.g., leg).

Processing then flows to decision block **52**. If decision block **52** indicates that stationary analysis should be performed (i.e. only a single frame from the imaging system is being processed) then processing proceeds to block **54** and, during stationary analysis, the angles are connected to continuous lines (i.e. contours) using basic spline functions. It should be noted that techniques other than spline functions can also be used to connect to the continuous lines (including but not limited to two straight lines, etc). To date, however, it has been found that a spline is the smoothest and simplest technique. It should also be noted that the above-described method of finding tangent planes and creating strain tensors requires all eight (8) surrounding points. Processing then ends.

If, on the other hand, a decision is made in decision block **46** that the principle strains are of the same sign, meaning there is only local extension or local compression, then the minimum extension or minimum compression is recorded, respectively, as shown in block **49**. Processing then flows to decision block **52** and to appropriate ones of blocks **54**, **56** as described above. If decision block **52** indicates that motion analysis should be performed (i.e. the imaging system produces multiple frames to capture motion of a body part), then processing flows to decision block **56** which implements a loop in which the process from blocks **34** to **56** is repeated until all frames are processed. Once all frames are processed, then processing ends.

Referring now to FIGS. **3A** and **3B**, a body part has a plurality of exemplary reflecting, spherical markers, generally denoted **60**, disposed thereon. In this exemplary embodiment, the body part is a right leg having one hundred and forty-four (144) markers **50** disposed thereon. It should be noted that FIG. **3A** shows the anterior of the leg and FIG. **3B** shows the posterior of the right leg.

Also, in this exemplary embodiment, the markers are provided as four millimeter (4 mm) and six (6) mm infrared reflecting, spherical markers. It should, of course, be appreciated that other types, sizes and shapes of markers may be used, In short, any marker which allows the collection of data suitable for use in the processing described herein may be used.

Referring now to FIGS. 4A and 4B, a graphical explanation is shown of how strain pairs are rotated onto the new axes defined by the position of the marker directly above. Eight points 68a-68h are used. It should be noted that the point corresponding to ϵ_{270} is not used because its similarity to ϵ_y causes large error. The strain values ϵ_{xy} and ϵ_x are averaged for the final results.

FIG. 5A illustrates a motion capture reconstruction of reflective markers on a bent leg. The left-most column 401 indicates the anterior of the leg.

FIG. 5B is a map of longitudinal strains that occur as the leg moves from an extended position to a flexed position.

FIG. 5C shows a pattern of lines of non-extension calculated from the strain field seen in FIG. 5B. Two lines 410, 412 consistent with the pattern on the posterior of the knee are highlighted.

Referring now to FIG. 6 a system 500 for measuring and modeling skin movement and for quantifying skin movement and deriving strain fields, contours and three-dimensional patterns includes a data collection system 510 which collects data from an appropriately marked body under test 512. System 500 is appropriate, for example, to perform the measurement and data processing techniques described herein.

Significantly, data collection system collects from the body under test while the body is at rest (i.e. static data collection) and while the body is undergoing a motion (i.e. dynamic data collection). It should be appreciated that body under test 512 is here shown in phantom since it is not properly a part of the system 500 for measuring and modeling skin movement and for quantifying skin movement and deriving strain fields, contours and three-dimensional patterns.

Data collection system 510 provides the data to a processing system 514 which processes the data to model and quantify skin movement and to derive strain fields, contours and three-dimensional patterns in accordance with the techniques described hereinabove.

In the exemplary embodiment of FIG. 5, data collection system 510 includes a motion capture system 516 and a tracking system 518 which may be provided for example as a three-dimensional laser tracker system. In one embodiment, motion capture system 516 is provided as an eight camera Vicon (Centennial, Colo.) motion capture system.

Motion capture system 510 collects or otherwise obtains position data at the locations of the marker points as discussed above in conjunction with FIGS. 3A, 3B. Data collection system 510 provides the data to processing system 514 and in particular to a data store 520 of processing system 514. Processing system 514 further includes a lines of non-extension (LONEs) processor 522, a principle strain processor 524 and a three-dimensional pattern processor 526 all of which are coupled to receive (either directly or indirectly) data from the data store.

LONEs processor 522 analyzes changes in distance between position data at each marker point and its closest neighbors from initial position to deformation. When a rectangular grid (such as that shown in FIGS. 3A, 3B is used), closest neighbors are considered to be the two markers adjacent in the same row and also the three markers in the rows above and below in the corresponding columns. In one embodiment, because the strains are so large, LONEs processor 522 calculates second order Lagrangian strains using the following equation:

$$\varepsilon = \frac{l^2 - l_0^2}{2l_0^2} = \frac{\Delta l}{l_0} + \frac{(\Delta l)^2}{2l_0^2};$$

In which:
l is the new distance between two points;
l_o is the original length between two points; and
Δl is the difference between the two;

LONEs processor 522 then projects the 3D strains surrounding each data point onto a two-dimensional (2D) plane tangent to the body skin at each marker position. The 2D plane is created by first averaging the normal vectors to the planes between each neighboring pair of strain vectors wherein the new average normal of eight (8) different planes defines the normal vector to the tangential plane created at the marker position. After being projected onto the tangential plane the strains are then rotated in pairs onto the axes defined by the location of the marker directly above (as described above in conjunction with FIGS. 4A and 4B) and then averaged together to give the longitudinal strain (ϵ_y), the circumferential strain (ϵ_x), and the shear strain (ϵ_{xy}).

Principle strain processor 524 performs an eigenvector analysis to determine the principle strains (ϵ_I and ϵ_{II}). In response to the principle strains being of opposite signs, meaning there is both extension and compression, they are used to mathematically determine the angle of the lines of non-extension ϕ with the known equations:

$$\tan^2\phi = \frac{\varepsilon_I(2+\varepsilon_I)}{-\varepsilon_{II}(2+\varepsilon_{II})} \quad \tan^2\phi = \frac{(1-\varepsilon_I)^2(\varepsilon_I(2+\varepsilon_I))}{(1+\varepsilon_{II})^2(1-(1+\varepsilon_{II})^2)}$$

where the first equation is the angle between the primary eigenvector and the line of non-extension projected onto the initial position and the second equation is the same angle projected onto the deformed position.

In response to the principle strains having the same sign, meaning there is only local extension or local compression, then processor 524 records the minimum extension or minimum compression and projects these angles onto the body surface and, during primarily stationary analysis only, connects them to continuous lines. This may be accomplished, for example, using basic spline functions. This exemplary method of finding tangent planes and creating strain tensors requires all (eight) 8 surrounding points. It should of course be appreciated that in some embodiments less than eight (8) points can be used. In the exemplary embodiment described herein, the eight (8) points (e.g. as illustrated in FIGS. 4A, 4B) are in close proximity and increasing the number of (close) points increases the accuracy of the measurement.

In one embodiment, with respect to stationary data collection, the motion capture system was able to accurately capture a grid of markers spaced approximately 3 cm apart (e.g. as shown in FIG. 5A). Preliminary analysis identified maximum longitudinal strains less than 0.40, within the physical limitations of skin, in an appropriate distribution (FIG. 5B). The process for calculating lines of non-extension from the strain field data (e.g. as described in conjunction with FIGS. 2A, 2B above) found a pattern of lines of non-extension as shown in FIG. 5C.

The entire range of strain (maximum and minimum of the total strain), longitudinal strain, circumferential strain, and sheer strain for each data point are found.

A three-dimensional pattern processor 526 processes the data provided thereto to connect the calculated angles from

LONES processor **522** from each data point into anatomically feasible contours. In this way, the system is capable of generating designs for flexible apparel. Such apparel includes but is not limited to athletic or other clothing, portions of space suits and in particular. The system is also useful for generating designs of tissue-engineering scaffolds, medical diagnosis for skin surgery and the design and development of soft exoskeletons.

In one exemplary embodiment the above described technique was utilized on a knee. In this exemplary embodiment, an eight camera Vicon (Centennial, Colo.) motion capture system was used to track one hundred forty four (144) 4-mm and 6-mm spherical reflective markers positioned approximately 3 cm apart around a healthy adult female knee joint with care taken to make a grid with the markers aligned in rows and columns (see FIGS. **3**A, **3**B). In the exemplary embodiment shown in FIGS. **3**A, **3**B the markers are disposed in a substantially rectangular grid pattern. Other patterns (both grid and non-grid patterns—e.g. lattice patterns) may, of course, also be used. In preferred embodiments, the markers are disposed in a uniform grid pattern. Such a grid pattern facilitates use of nearest neighbor computations. It should also be appreciated that the distance between markers impacts the accuracy of anatomical representations and the ability to make physiological implications. Thus, the closer the spacing of the markers, the more accurate the anatomical representation and the greater the ability to make physiological implications based upon the anatomical representation. Of course, by spacing markers more closely in a given area (e.g. 1 cm spacing or less), the larger the number of data points which will be generated and consequently the more time it takes to perform computations. Thus, a trade-off may be made between the amount of data needed and the time required to measure and process the data. In one embodiment, the resolution of the motion capture system is the limiting factor in selecting spacing between markers.

With the markers are properly positioned, stationary (i.e. static) data collection is performed. Position data is captured by the motion capture system with the body joint (e.g., knee) extended (initial position) and then again with the body joint flexed (final position).

The acquired position data is filtered and averaged so there is one position for each marker in each position, which then serves as input to the analysis/calculations methodology described above.

Also, with the markers properly positioned, motion (i.e. dynamic) data collection can be performed. It should be noted that the same body marker grid should be used in both the stationary (i.e. static) data collection and the motion (dynamic) data collection. Motion capture position data are collected for an entire flexion and extension cycle (~6 seconds) for the entire movement for every/any body joint. In the dynamic case (e.g. 2-6 seconds of movement captured at a rate of about 15-30 frames per second), an analysis program compares each frame to the initial position (first frame). The resultant output is strain data for each point that can be combined and analyzed over time or for the duration of the movement. Significantly, the system also can be used to produce video files to display the strain and directions of the non-extending lines graphically on a 3D reconstruction of the body (e.g., leg).

The technique described herein allows new data to be generated and with this new data, one can calculate the lines of non-extension, or contours of the skin that remain a constant length during motion as described herein above.

The system and techniques described herein result in a new understanding of the relationship between the structure of skin and the strains it experiences during natural joint movement. The system and techniques described herein may find application in a wide variety of areas including, but not limited to, design of tissue-engineering scaffolds, medical diagnosis for skin surgery, the design and development of soft exoskeletons, commercial spacesuits and athletic garments.

It should also be appreciated that the above-described techniques can be used to calculate the angle of the line of non-extension, line of minimum extension, or line of minimum compression for each frame.

Referring now to FIG. **7**, a computer **752** suitable for supporting the operation of an embodiment of the inventive systems, concepts, and techniques described herein includes a processor **754**. Processor **754** may, for example, be provided as a dual-core processor, such as one of the types available from the Advanced Micro Devices Corporation of from Intel Corporation. However, it should be understood that computer **752** may use other microprocessors. Computer **752** can represent any server, personal computer, laptop, or even a battery-powered mobile device such as a hand-held personal computer, personal digital assistant, or smart phone.

Computer **752** includes a system memory **756** which is connected to the processor **754** by a system data/address bus **762**. System memory **756** includes a read-only memory (ROM) **758** and random access memory (RAM) **760**. The ROM **758** represents any device that is primarily read-only including electrically erasable programmable read-only memory (EEPROM), flash memory, etc. RAM **760** represents any random access memory such as Synchronous Dynamic Random Access Memory (SDRAM). The Basic Input/Output System (BIOS) 196 for the computer **752** is stored in ROM **758** and loaded into RAM **760** upon booting.

Within the computer **752**, input/output (I/O) bus **764** is connected to the data/address bus **762** via a bus controller **766**. In one embodiment, the I/O bus **764** is implemented as a Peripheral Component Interconnect (PCI) bus. The bus controller **766** examines all signals from the processor **754** to route signals to the appropriate bus. Signals between processor **754** and the system memory **756** are passed through the bus controller **766**. However, signals from the processor **754** intended for devices other than system memory **756** are routed to the I/O bus **764**.

Various devices are connected to the I/O bus **764** including internal hard drive **768** and removable storage drive **770** such as a CD-ROM drive used to read a compact disk **771** or a floppy drive used to read a floppy disk. The internal hard drive **768** is used to store data, such as in files **774** and database **776**. Database **776** may include, for example, a structured collection of data, such as a relational database. A display **772**, such as a cathode ray tube (CRT), liquid-crystal display (LCD), etc. is connected to the I/O bus **764** via a video adapter **778**.

A user enters commands and information into the computer **752** by using input devices **780**, such as a keyboard and a mouse, which are connected to I/O bus **764** via I/O ports **781**. Other types of pointing devices that may be used include track balls, joy sticks, and tracking devices suitable for positioning a cursor on a display screen of the display **772**.

Computer **752** may include a network interface **786** to connect to a remote computer **782**, an intranet, or the Internet via network **784**. The network **784** may be a local area network or any other suitable communications network. Data from external systems (e.g. a data collection system such as that described above in conjunction with FIG. **6**) may be provided tom computer **752** through various computer I/O ports and/or network connections.

Computer-readable modules and applications **788** and other data are typically stored on memory storage devices,

which may include the internal hard drive **768** or the compact disk **771**, and are copied to the RAM **760** from the memory storage devices. In one embodiment, computer-readable modules and applications **788** are stored in ROM **758** and copied to RAM **760** for execution, or are directly executed from ROM **758**. In still another embodiment, the computer-readable modules and applications **788** are stored on external storage devices, for example, a hard drive of an external server computer, and delivered electronically from the external storage devices via network **784**.

The computer-readable modules **788** may include compiled (or compilable) instructions for implementing embodiments of one or more of: a LONEs processor, a principle strains processor or a skin orientation processor and methods described herein. Skin movement and/or strain data may be rendered and outputted to display **772** to enable users to graphically view the data (e.g. as shown in FIGS. **3A-5C**).

In a further embodiment, the computer **752** may execute various processes on separate processors, such as a first processor and a second processor of a dual core processor. As by way of a non-limiting example, control of data collections operations (e.g. to receive and respond to data from a data collection system) may be executed by the first processor and skin and strain operations (e.g., to compute LONEs and strain values) may be executed by the second processor. Alternatively, the first and second processors may be respective first and second computing devices.

The computer **752** may execute a database application **790**, such as Oracle™ database from Oracle Corporation, to model, organize, and query data stored in database **776**. The data may be used by the computer-readable modules and applications **788** and/or passed over the network **784** to the remote computer **782** and other systems.

In general, the operating system **792** executes computer-readable modules and applications **788** and carries out instructions issued by the user. For example, when the user wants to execute a computer-readable module **788**, the operating system **792** interprets the instruction and causes the processor **754** to load the computer-readable module **788** into RAM **760** from memory storage devices. Once the computer-readable module **788** is loaded into RAM **760**, the processor **754** can use the computer-readable module **788** to carry out various instructions. The processor **754** may also load portions of computer-readable modules and applications **788** into RAM **760** as needed. The operating system **792** uses device drivers **794** to interface with various devices, including memory storage devices, such as hard drive **768** and removable storage drive **770**, network interface **786**, I/O ports **781**, video adapter **778**, and printers.

It should be appreciated that the processes described herein (e.g. in conjunction with FIGS. **2A** and **2B**, for example) are not limited to use with the hardware and software of FIG. **7**. Rather, they may find applicability in any computing or processing environment and with any type of machine or set of machines that is capable of running a computer program.

It should also be appreciated that the processes described herein (e.g. in conjunction with FIGS. **2A** and **2B**, for example) may be implemented in hardware, software, or a combination of the two. The processes described herein may be implemented in computer programs executed on programmable computers/machines that each includes a processor, a storage medium or other article of manufacture that is readable by the processor (including volatile and non-volatile memory and/or storage elements), at least one input device, and one or more output devices. Program code may be applied to data entered using an input device to perform one or more of the processes and/or to generate output information.

The system may be implemented, at least in part, via a computer program product, (e.g., in a machine-readable storage device), for execution by, or to control the operation of, data processing apparatus (e.g., a programmable processor, a computer, or multiple computers)). Each such program may be implemented in a high level procedural or object-oriented programming language to communicate with a computer system. However, the programs may be implemented in assembly or machine language. The language may be a compiled or an interpreted language and it may be deployed in any form, including as a stand-alone program or as a module, component, subroutine, or other unit suitable for use in a computing environment. A computer program may be deployed to be executed on one computer or on multiple computers at one site or distributed across multiple sites and interconnected by a communication network. A computer program may be stored on a storage medium or device (e.g., CD-ROM, hard disk, or magnetic diskette) that is readable by a general or special purpose programmable computer for configuring and operating the computer when the storage medium or device is read by the computer to perform processes. The processes described herein may also be implemented as a machine-readable storage medium, configured with a computer program, where upon execution, instructions in the computer program cause the computer to operate in accordance with processes.

The processes described herein are not limited to the specific embodiments described. For example, the process described in FIGS. **2A** and **2B** are not limited to the specific processing order shown in FIGS. **2A** and **2B**, respectively. Rather, unless otherwise precluded, any of the processing blocks of FIGS. **2A** and **2B** may be re-ordered, combined or removed, performed in parallel or in serial, as necessary, to achieve the results set forth above.

The processing described herein (e.g. in conjunction with FIGS. **2A**, **2B**) associated with implementing the system and/or the techniques described herein may be performed by one or more programmable processors executing one or more computer programs to perform the functions of the system. All or part of the system may be implemented as, special purpose logic circuitry (e.g., an FPGA (field programmable gate array) and/or an ASIC (application-specific integrated circuit)) and/or neural networks.

Also, it should be appreciated that elements of different embodiments described herein may be combined to form other embodiments not specifically set forth above. Other embodiments not specifically described herein are also within the scope of the following claims.

Having described preferred embodiments of the concepts, systems, circuits and techniques described herein, it will now become apparent to those of ordinary skill in the art that other embodiments incorporating these concepts may be used. For example, it should now be appreciated that one can apply the topologies described herein to rectifier systems (e.g. for grid-connected power supplies) as well and for bidirectional power flow converter systems. Accordingly, it is submitted that that the concepts, systems, circuits and techniques described herein, should not be limited to the described embodiments but rather should be limited only by the spirit and scope of the appended claims.

The invention claimed is:

1. A system to measure skin movement and strain on a body under test, the system comprising:

a data collection system which collects data from the body under test wherein the data collection system is adapted to collect data from the body under test while the body is at rest and while the body is undergoing a motion;

a processing system coupled to receive data from said data collection system, said processing system for processing the data to model and quantify skin movement and to derive strain fields, contours and three-dimensional patterns of skin on the body under test;

wherein said data collection system comprises:

a motion capture system which obtains position data at locations identified by a plurality of markers disposed on the surface of the skin of the body under test; and

a tracking system corresponding to a three-dimensional laser tracker system wherein said processing system comprises a lines of non-extension (LONEs) processor coupled to receive data from said data collection system and to analyze changes in distance between position data at each marker point and its closest neighbors from initial position to deformation;

wherein said LONEs processor calculates second order Lagrangian strains in accordance with:

$$\varepsilon = \frac{l^2 - l_0^2}{2l_0^2} = \frac{\Delta l}{l_0} + \frac{(\Delta l)^2}{2l_0^2};$$

In which:

l is the new distance between two points;

l_o is the original length between two points; and

Dl is the difference between the two.

2. The system of claim **1** wherein said LONEs processor projects 3D strains surrounding each data point onto a two-dimensional (2D) plane tangent to the body skin at each marker position.

3. The system of claim **2** wherein after being projected onto the tangential plane, said LONEs processor rotates the strains in pairs onto the axes defined by a location of a marker directly above and then averaged together to provide a longitudinal strain value (ϵ_y), a circumferential strain value (ϵ_x), and a shear strain value (ϵ_{xy}).

4. The system of claim **3** wherein said principle strain processor performs an eigenvector analysis to determine the principle strains (ϵ_I and ϵ_{II}) wherein In response to the principle strains being of opposite signs, using the principle strains (ϵ_I and ϵ_{II}) to determine the angle of the lines of non-extension.

5. The system of claim **4** wherein In response to the principle strains being of opposite signs, said principle strain processor uses the principle strains (ϵ_I and ϵ_{II}) to mathematically determine the angle of the lines of non-extension with the known equations:

$$\tan^2 \phi = \frac{\varepsilon_I (2 + \varepsilon_I)}{-\varepsilon_{II}(2 + \varepsilon_{II})} \quad \tan^2 \phi = \frac{(1 - \varepsilon_I)^2 (\varepsilon_I (2 + \varepsilon_I))}{(1 + \varepsilon_{II})^2 (1 - (1 + \varepsilon_{II})^2)}$$

where the first equation is the angle between the primary eigenvector and the line of non-extension projected onto the initial position and the second equation is the same angle projected onto the deformed position.

6. A method for computing lines of non-extension comprising:

(a) obtaining position data using a motion capture system, wherein obtaining position data comprises obtaining three-dimensional (3D) positions of a plurality of marker points disposed on body skin surrounding a joint of a test subject, wherein obtaining 3D positions of the plurality of marker points includes obtaining 3D positions of the marker points with the joint of the test

subject in an initial position, moving the joint of the test subject to a deformed position, and obtaining 3D positions of the marker points with the joint of the test subject in the deformed position, wherein the plurality of marker points form a rectangular grid on the body skin of the test subject;

(b) analyzing changes in distance between each marker point and that marker point's closest neighbors from the initial position to the deformed position, wherein the closest neighbors include adjacent marker points in the same row of the rectangular grid, adjacent marker points in the same column of the rectangular grid, and adjacent marker points disposed diagonally in the rectangular grid;

(c) determining one or more 3D strains surrounding each marker point, wherein determining one or more 3D strains includes calculating second order Lagrangian strains;

(d) projecting 3D strains surrounding each marker point onto a two-dimensional (2D) plane tangent to the body skin at the corresponding marker point;

(e) after projecting 3D strains onto the 2D tangential plane for each marker point, rotating the projected strains in pairs onto axes defined with respect to the location of the corresponding marker point;

(f) averaging the rotated pairs for each axis associated with each marker point to generate a longitudinal strain (ϵ_y), a circumferential strain (ϵ_x), and a shear strain (ϵ_{xy});

(g) determining principle strains (ϵ_I and ϵ_{II}) for each marker point;

(h) if the principle strains associated with a first marker point have opposite signs, determining an angle of a line of non-extension for the first marker point using the principle strains associated with the first marker point;

(i) if the principle strains associated with the first marker point have the same sign, recording an angle of minimum extension or minimum compression for the first marker point and projecting the angle of minimum extension or minimum compression onto the body surface.

7. The method of claim **6** further comprising:

repeating (h) and (i) for other marker points in the plurality of marker points; and

connecting angles of lines of non-extension into contours.

8. The method of claim **6** wherein:

obtaining three dimensional positions of the marker points includes obtaining three dimensional positions of the marker points with the joint of the test subject in positions other than the initial position and the deformed position as part of a motion analysis; and

repeating (b) through (i) for successive frames of the motion analysis.

9. The method of claim **6** wherein calculating second order Lagrangian strains includes using the following equation:

$$\varepsilon = \frac{l^2 - l_0^2}{2l_0^2} = \frac{\Delta l}{l_0} + \frac{(\Delta l)^2}{2l_0^2};$$

In which:

ϵ is the second order Lagrangian strain for two points;

l is a new distance between the two points;

l_o is an original distance between the two points; and

Δl is a difference between the new distance and the original distance.

15

10. The method of claim **6** wherein determining an angle of a line of non-extension for the first marker point using the principle strains associated with the first marker point includes using the equations:

$$\tan^2\phi = \frac{\varepsilon_I(2+\varepsilon_I)}{-\varepsilon_{II}(2+\varepsilon_{II})} \quad \tan^2\phi = \frac{(1-\varepsilon_I)^2(\varepsilon_I(2+\varepsilon_I))}{(1+\varepsilon_{II})^2(1-(1+\varepsilon_{II})^2)}$$

wherein the equations correspond to the angle between a primary eigenvector and the line of non-extension projected onto the initial position and the deformed position, respectively, wherein ε_I and ε_{II} are the principle strains.

11. The method of claim **6** further comprising: generating the 2D tangential plane for each marker point, before projecting the 3D strains, by averaging normal vectors to the planes between each neighboring pair of strain vectors associated with the corresponding marker point, wherein a neighboring pair of strain vectors comprises strain vectors associated with two closest neighbor marker points that are adjacent to one another.

12. The method of claim **11** wherein averaging normal vectors includes averaging normal vectors associated with eight (8) different planes.

13. The method of claim **6** wherein determining the principle strains (ε_I and ε_{II}) comprises performing an eigenvector analysis to determine the principle strains (ε_I and ε_{II}).

14. A method to measure movement and strain, the method comprising:

(a) obtaining position data associated with body skin of a test subject using a motion capture system, the position data corresponding to a plurality of marker points disposed on the body skin around a joint of the test subject, wherein obtaining position data includes obtaining position data for multiple different orientations of the joint of the test subject;

(b) computing angles of lines of non-extension for various marker points on the body skin of the test subject using the collected position data wherein computing angles of lines of non-extension includes;

(b1) determining one or more three-dimensional (3D) strains surrounding each marker point;

(b2) computing a two-dimensional (2D) plane tangent to the body skin at each marker point at which position data of body skin was taken in (a);

(b3) projecting the 3D strains surrounding each marker point onto the corresponding 2D plane tangent to the body skin;

(b4) computing values for longitudinal strain (ε_y), circumferential strain (ε_x), and shear strain (ε_{xy}) for each marker point;

(b5) determining principle strains (ε_I and ε_{II}) for each marker point;

(b6) if the principle strains associated with a first marker point have opposite signs, using the principle strains to mathematically determine an angle of a line of non-extension for the first marker point;

(b7) repeating (b6) for other marker points within the plurality of marker points; and

(c) connecting the angles of lines of non-extension into contours for use in performing at least one of: flexible apparel design, tissue-engineering scaffold design, soft exoskeleton design, and skin surgery.

15. The method of claim **14** further comprising if the principle strains associated with the first marker point have a

16

common sign, recording an angle of minimum compression or minimum extension for the first marker point.

16. The method of claim **14** further comprising projecting strains onto the surface for analysis.

17. A method to measure skin movement and strain, the method comprising:

(a) obtaining position data of body skin using a motion capture system, wherein obtaining position data comprises obtaining three dimensional (3D) positions of a plurality of marker points disposed on the body skin surrounding a joint of a test subject, wherein obtaining 3D positions of the plurality of marker points includes obtaining 3D positions of the marker points with the joint of the test subject in an initial position, moving the joint of the test subject to a deformed position, and obtaining 3D positions of the marker points with the joint of the test subject in the deformed position, wherein the plurality of marker points form a rectangular grid on the body skin of the test subject;

(b) analyzing changes in distance between each marker point and that marker point's closest neighbors from the initial position to the deformed position, wherein the closest neighbors include adjacent marker points in the same row of the rectangular grid, adjacent marker points in the same column of the rectangular grid, and adjacent marker points disposed diagonally in the rectangular grid;

(c) determining one or more 3D strains surrounding each marker point;

(c1) generating a two-dimensional (2D) plane tangent to the body skin at each marker point by averaging normal vectors to the planes between each neighboring pair of strain vectors associated with the corresponding marker point, wherein a neighboring pair of strain vectors comprises strain vectors associated with two closest neighbor marker points that are adjacent to one another;

(d) projecting the 3D strains surrounding each marker point onto the corresponding 2D plane;

(e) after projecting the 3D strains onto the 2D tangential plane for each marker point, rotating the projected strains in pairs onto axes defined with respect to the corresponding marker point;

(f) averaging the rotated pairs for each axis associated with each marker point to generate a longitudinal strain value (ε_y), a circumferential strain value (ε_x), and a shear strain value (ε_{xy}) for the marker point;

(g) determining principle strain values (ε_I and ε_{II}) for each marker point using eigenvector analysis;

(h) if the principle strain values associated with a marker point have opposite signs, using the principle strain values to determine an angle of a line of non-extension for the marker point; and

(i) if the principle strain values associated with a marker point have a common sign, recording an angle of minimum extension or an angle of minimum compression for the marker point.

18. The method of claim **17** wherein obtaining position data comprises obtaining 3D positions of the marker points with the joint of the test subject in positions other than the initial position and the deformed position.

19. The method of claim **17** wherein determining one or more 3D strains surrounding each marker point comprises computing one or more second order Lagrangian strains.

20. The method of claim **17** wherein generating a 2D plane tangent to the body skin at each marker point includes averaging eight normal vectors for each marker point.

21. The method of claim **17** wherein using the principle strains associated with a marker point to determine the angle of a line of non-extension for the marker point comprises using the principle strains to mathematically determine the angle of the line of non-extension using the equations:

$$\tan^2\phi = \frac{\varepsilon_I(2 + \varepsilon_I)}{-\varepsilon_{II}(2 + \varepsilon_{II})} \quad \tan^2\phi = \frac{(1 - \varepsilon_I)^2(\varepsilon_I(2 + \varepsilon_I))}{(1 + \varepsilon_{II})^2(1 - (1 + \varepsilon_{II})^2)}$$

wherein the equations correspond to the angle between a primary eigenvector and the line of non-extension projected onto the initial position and the deformed position, respectively, wherein ϵ_I and ϵ_{II} are the principle strains.

22. The method of claim **17** further comprising projecting the angle of minimum extension or the angle of minimum compression for the marker point onto the body skin.
