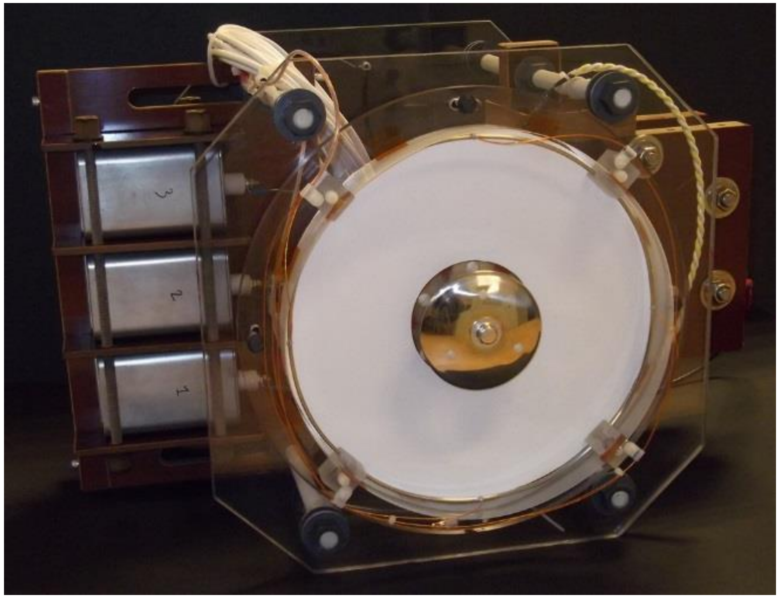
Introduction

- The Inductive Pulsed Plasma Thruster (IPPT) is an electromagnetic thruster that impulsively accelerates ionized propellant via the ***JxB*** body force.

- Potential advantages include:
    - Long operational life-time due to the absence of high-current electrodes
    - Ability to run on readily storable molecular propellants such as ammonia
    - I_{SP} can be independent of jet-power, P_{Jet}

- A small solid-state switched IPPT (*1-5 kWe) was* built with the goals of:
    - Demonstrating operation of an integrated solid-state switched IPPT.
    - Building a device that can be tested in cyclic mode on a thrust-stand.
    - Serve as a test-bed for solid state switching circuitry and pulsed gas valves.
    - The modular design of the device allows for a variety of configurations to be tested.



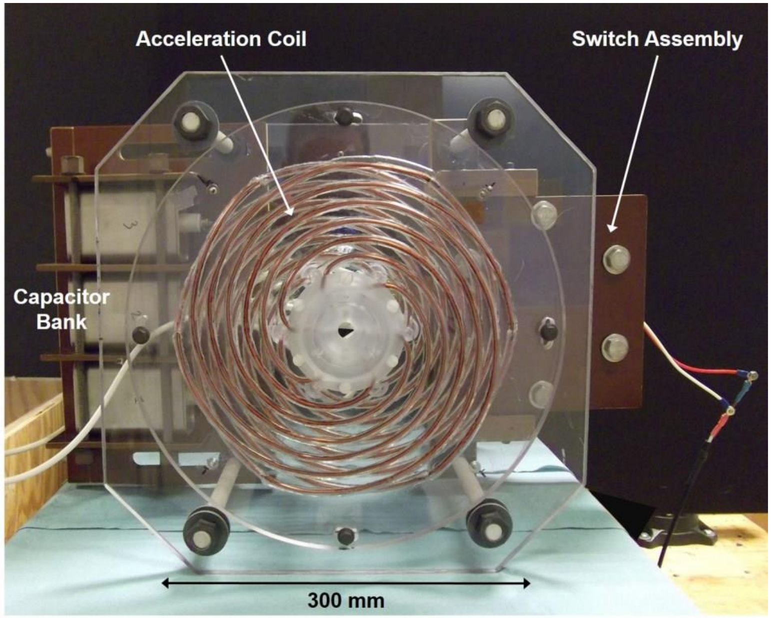
Design: Acceleration Coil

- The coil is wound on a Lexan coil form, and has six two-turn leads in parallel, clocked around the form at 60° intervals. Each turn is in the shape of an Archimedes-spiral ($r = a + b\theta$). The leads are No. 10 magnet wire, laid in CNC-machined grooves in a Lexan coil-form. Each lead is also insulated with Teflon heat-shrink tubing.

- Coil Dimensions:
  - o.d. = 270 mm
  - i.d. = 100 mm

- The coil is potted with Momentive RTV-560 high-voltage silicone insulation compound for additional insulation.

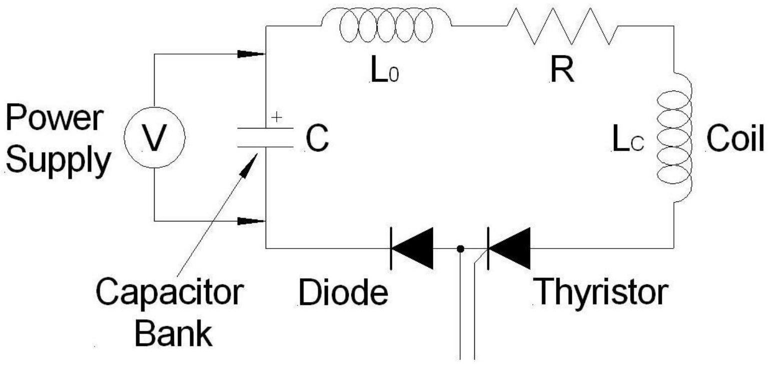
- The coil face was covered with an annular alumina-coated Mylar disk which provides insulation between the plasma and the coil and serves as a refractory plasma-facing wall.



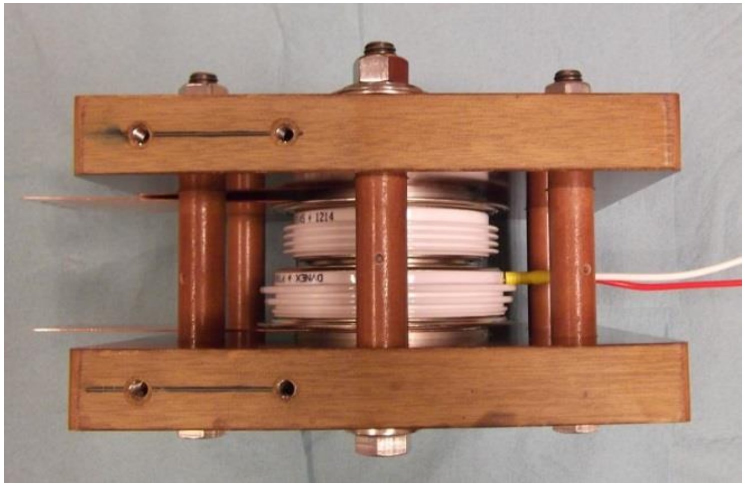
Partially assembled device with acceleration coil, capacitor bank, and switch assembly.

Design: Circuit and Switch Assembly

- Inductance: discussed later
- Capacitance: 9.88 μF
- Switch: Dynex PT85QWx45 pulse-power thyristor, 4.5 kV max. hold-off voltage, 30 kA surge current, max. *dI/dt* of 22 kA /μs
- Diode: Dynex DSF21545SV fast recovery diode, 20 kA max. current, 7 μs recovery time, 1.8 mC reverse recovery charge
- Thyristor and Diode are held in a clamp assembly and compressed with a force of 40 kN.



Acceleration coil circuit



Switch assembly with thyristor and diode.

Design: Gas Valve and Pre-ionizer

- Pulsed Gas-Valve: a modified solenoid fluid control valve
  - opening time of 300 μs.
  - 25-100 μg of propellant / pulse (in multi-pulse operation)
- Glow-discharge Pre-ionizer uses a 0.3 μF capacitor charged to ~ 4 kV

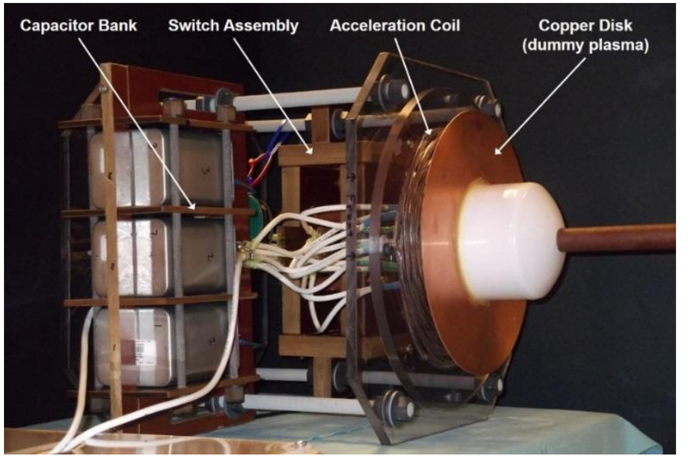
Bench-top Testing: Determination of Circuit Inductance

- Total circuit inductance was measured with the diode removed (ringing discharge)
- Coil inductance was calculated with QuickField v5.6
- Results from both were fit with the following function:

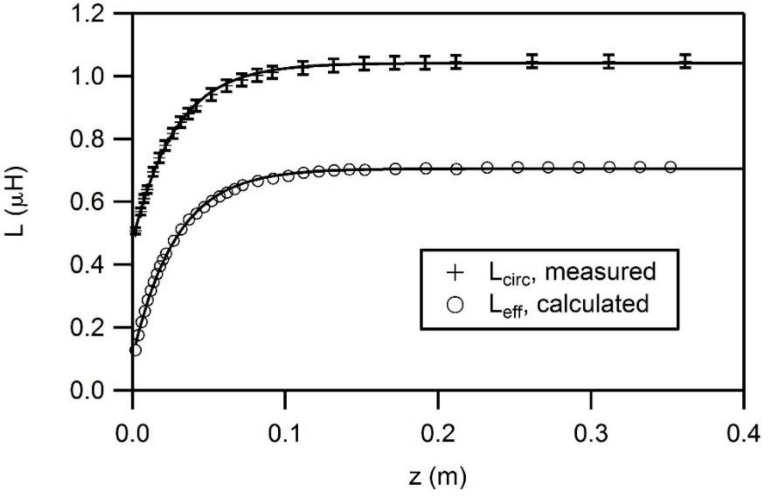
$$L(z) = L_{\infty}\left(1 - k_0^2\, e^{-2(z/z_S)}\right)$$

	Quantity fit to:	
Fitting Parameter:	L_{eff}	L_{circ}
L_{∞} (nH)	705 ± 3	1,041 ± 7
z_S (mm)	57 ± 1	57 ± 3
k_0	0.92 ± 0.01	NA
x^2 / n	0.4	0.1

- Calculated Coil Inductance: 705 nH
- Inferred External Inductance: 336 nH



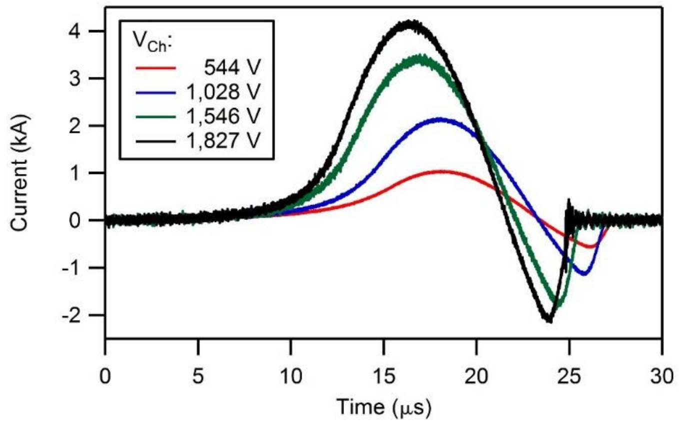
Experimental Setup



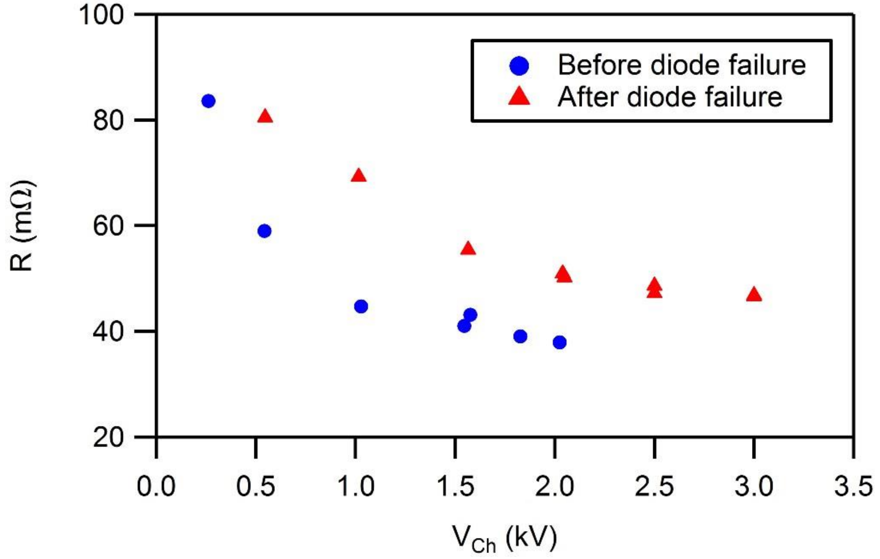
Inductance Measurement

Bench-top Testing: Component Testing at High Voltage

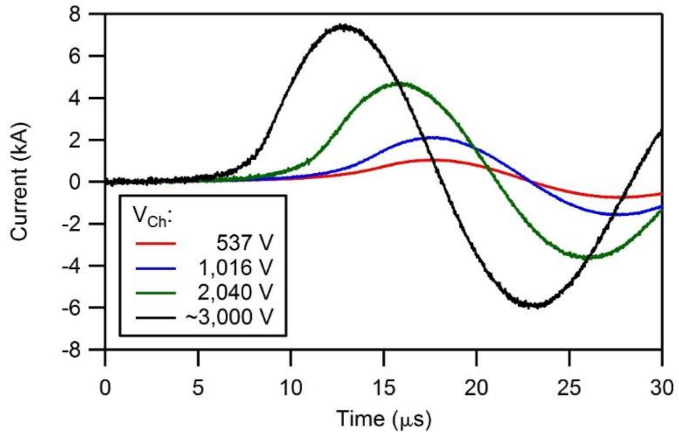
- Acceleration coil circuit tested up to 3 kV.
- Fast recovery diode failed at about 2 kV. at V_{Ch} ~ 1.8 kV, ΔQ = 4 mC > Q_{rr} = 1.8 mC
- Circuit Resistance decreases as V_{Ch} increases.



Before Diode Failure



Total Circuit Resistance



After Diode Failure

Vacuum Testing: Pre-ionizer

- Pre-ionizer capacitor with C = 0.3 μF charged to 4.1 kV: E_{PI} = 2.5 J
- Breakdown of the gas (argon) occurred when the valve is opened, allowing gas to bridge the electrodes
- The PI worked at cyclic rates of 1 Hz – higher rates are possible.

View of the thruster in the vacuum chamber

Pre-ionizer discharge

Vacuum Testing: Complete System

- Single-shot operation at V_{Ch} = 2 kV, with and without PI, Peak I_{Coil} = 4.05 kA
- A plasma formed even without the PI, i.e. just due to the *dI/dt* of the acceleration coil circuit itself
- The plasma formed with the PI appears to be brighter
- Repetitive operation demonstrated at cyclic-rate of 2 Hz
- A clog in the valve inlet was determined to have prevented operation at higher cyclic rates
- Insulation failures noticed after gas re-circulation in the chamber caused shorting.

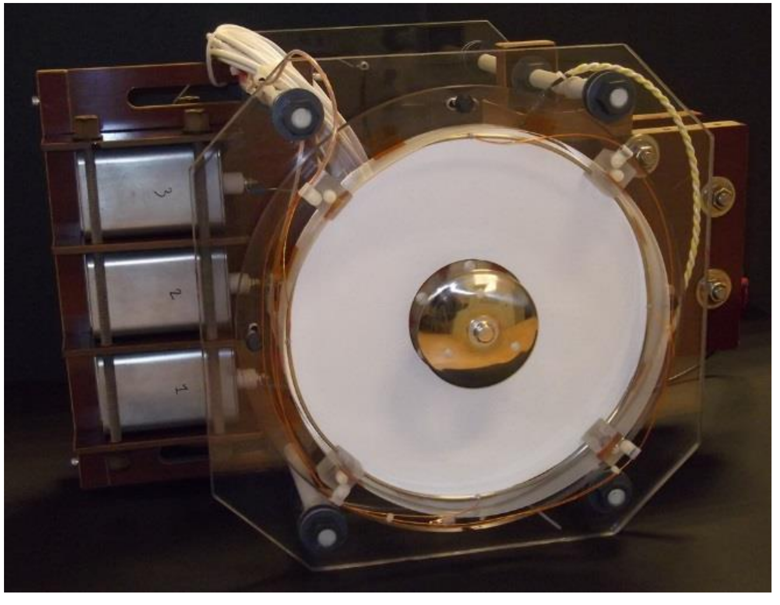
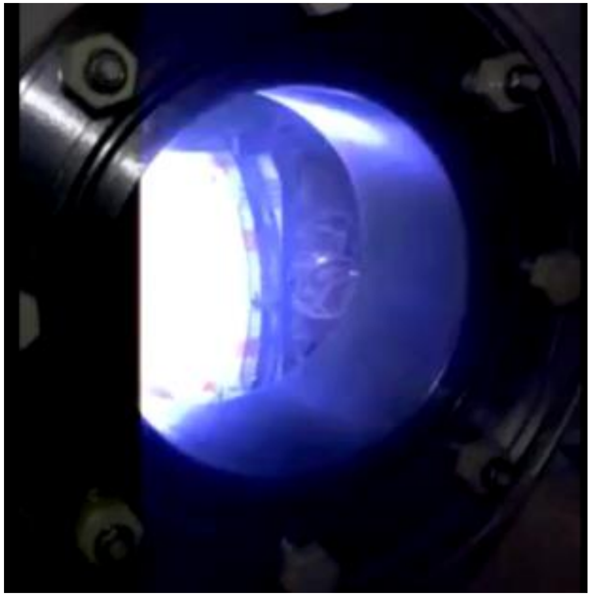
The IPPT thruster in operation

Conclusions and Future Work

- Cyclic operation of the IPPT has been demonstrated with all sub-systems functioning.
- Modifications are being made prior to next phase of testing:
  - Thyristor electrodes and terminations have been re-designed
  - HV insulation being re-done
  - Valve to be cleaned and rebuilt
- Subsequently, thruster to be installed in a larger chamber and thrust measurements made.





Acknowledgements

- The authors thank Jim Martin, Patrick McRight, Tom Williams, and Mary Beth Koelbl of the Marshall Space Flight Center (MSFC) Propulsion Systems Department and Mike LaPointe of the MSFC Technology Development and Transfer Office for continued management support and encouragement of this work.

- We also thank Emeritus Professor Ralph Lovberg (University of California San Diego) and Ashley Hallock (OHB Sweden AB) for many useful discussions about IPPTs.

- This work was in-part sponsored by the In-Space Propulsion Project of the Game-Changing Development (GCD) Program of NASA's Office of the Chief Technologist. The GCD principle investigator was Chuck Taylor (NASA Langley Research Center) and the project manager was Tim Smith (NASA Glenn Research Center).
