## Background

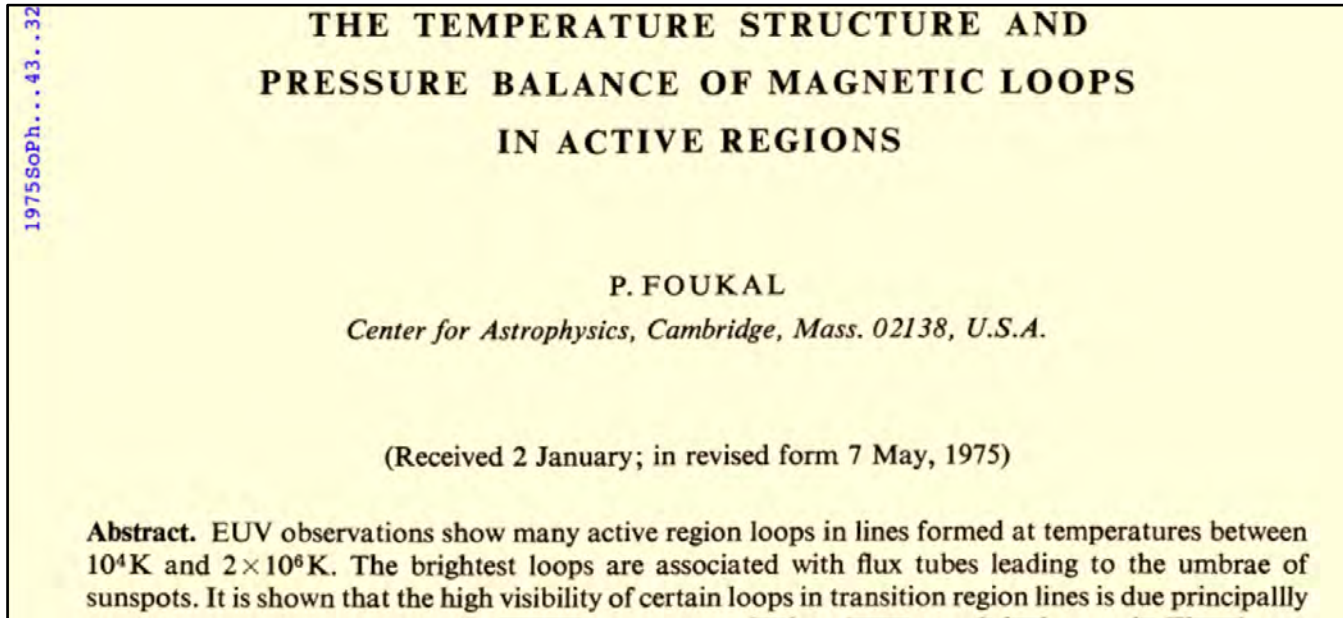

- Active regions are the brightest features in EUV and X-ray corona of the Sun  
Sounding rockets and Skylab (Vaiana et al. 1973, 1975) onwards....

## Background..

- Sunspots are dark on the surface and in the (X-ray) corona  
(Golub, Zirin & Wang, 1994: NIXT sounding rocket X-ray images)
- Sunspot umbrae have no or little X-ray and/or coronal EUV emissions  
(Pallavicini et al. 1979, Webb & Zirin 1981, Webb et al. 1983)
- None of the bright loops originate in sunspot umbrae  
(Sams III et al., 1992)

Inconsistent with the following...

- Loops rooted in sunspot umbra are the brightest ones among others (Foukal et al., 1974; Foukal, 1975; Webb & Zirin 1981)

Webb & Zirin 1981

- All flaring loops end in umbrae

Golub, Zirin & Wang, 1994

- The brightest features are the remains of small flares

Falconer et al. 1997

- Brightest loops are rooted near neutral lines
- Flux cancellation at feet might induce loop's coronal brightness

## Some obvious questions

- Why sunspots, particularly umbrae, are usually dim in coronal EUV and X-ray?
- What's special about some loops that stem from an umbra but are the AR's brightest loops in coronal EUV and X-ray at a given time?
- Does loop's rooting pattern, magnetic setting on the photosphere, tell us something about their coronal brightness?

## AIA 94 Å movie reveals that:

- Bright loops are episodic (~1-2h); repeated subflares are seen in sets of loops with indicative rooting pattern
- The brightest loops are rooted in umbra at one of their feet with their other foot in plage or penumbra of opposite polarity, and they never end in opposite polarity umbra.
- The plage-to-plage loops have only intermediate brightness
- AIA 94 images are dim in umbrae-> not all umbral loops are strongly heated; most umbral loops are weakly heated

- Transient loops (<30m life) follow the same pattern, i.e., the loops rooted in sunspot umbra are the hottest loops among others

from Alissandrakis & Patsourakos, 2013

# Example

## Umbral-to-umbral loops?

To test whether there are umbral-to-umbral coronal loops not visible (in any AIA channel):

we performed a NLFFF extrapolation

(Wiegmann et al. 2006; Wiegmann & Inhester, 2010)

- preprocessing applied to HMI vector magnetograms to achieve force-free boundary conditions for the modeling

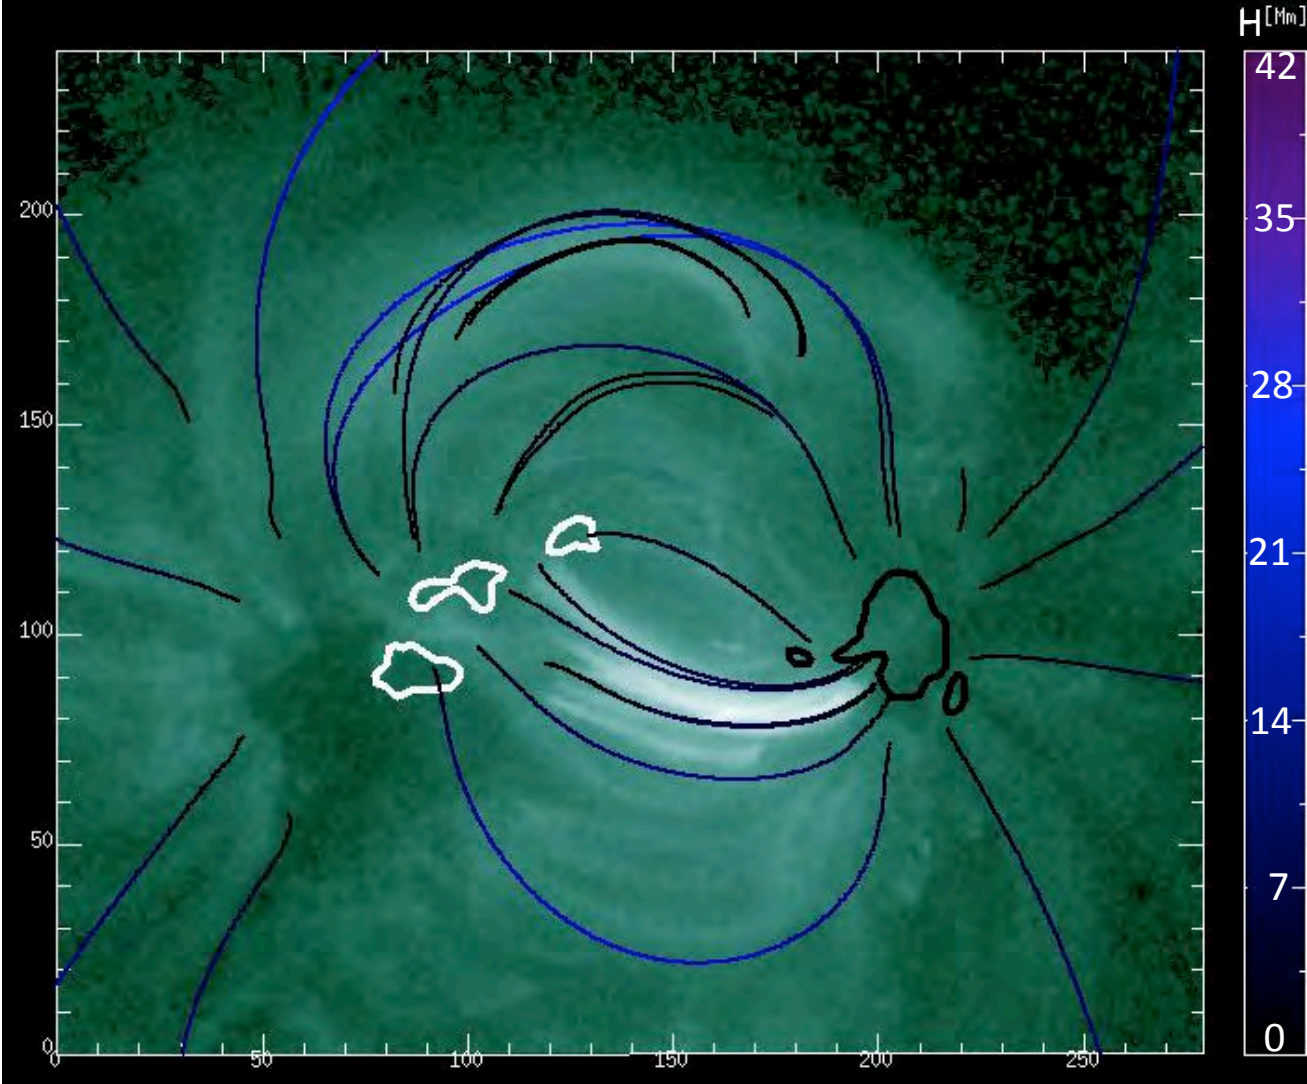

(performed by our collaborator Julia K. Thalmann)

## FOV selected for the NLFFF extrapolation

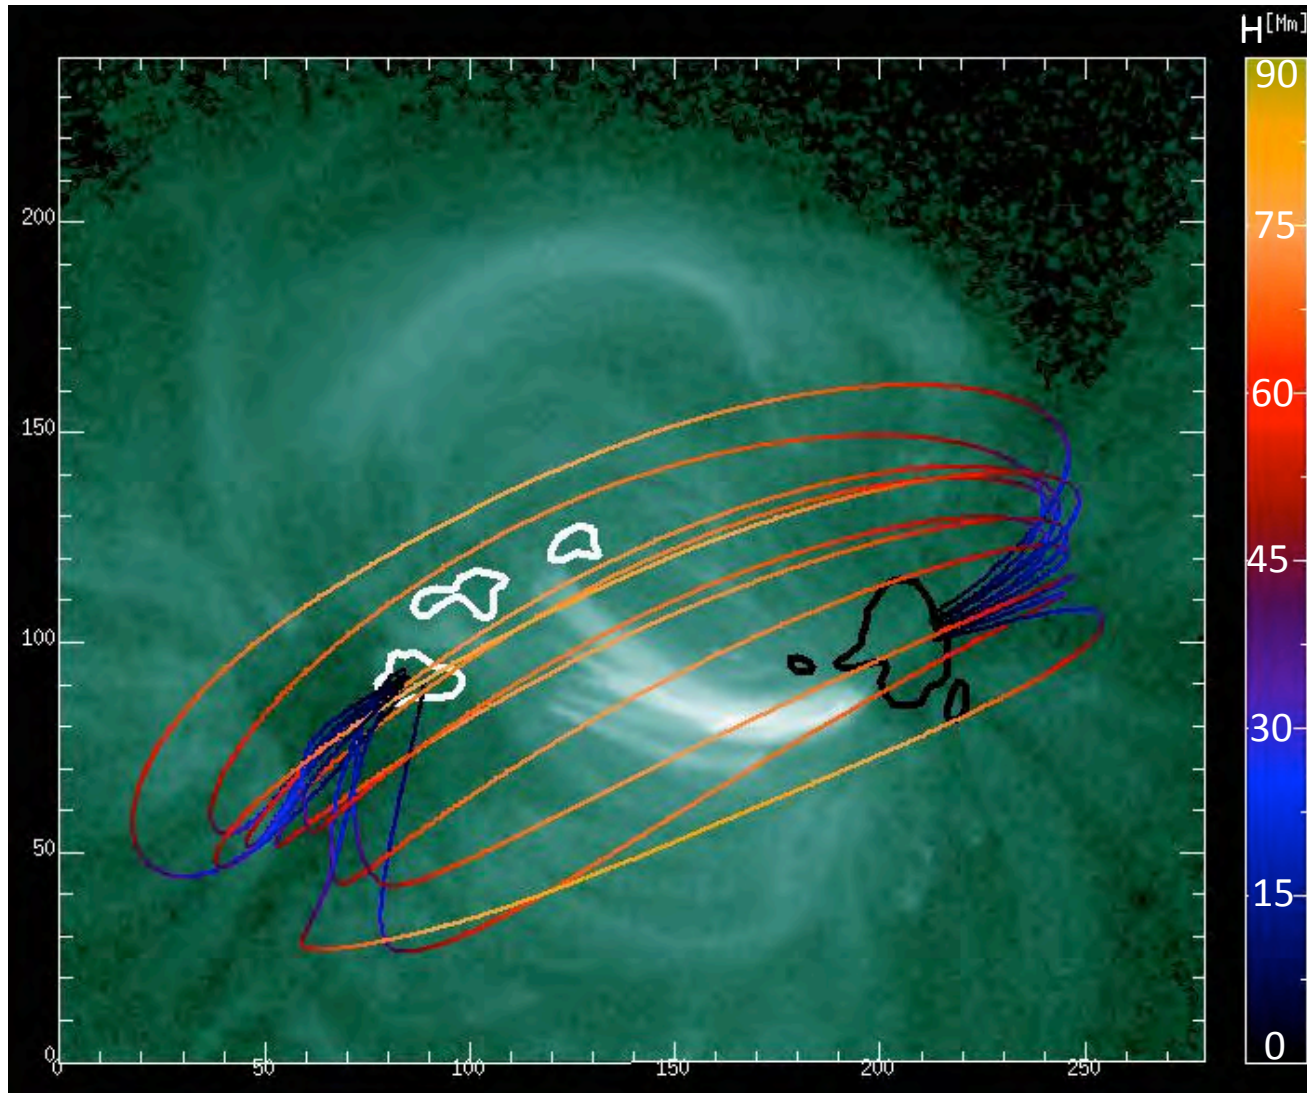

# NLFF model field lines

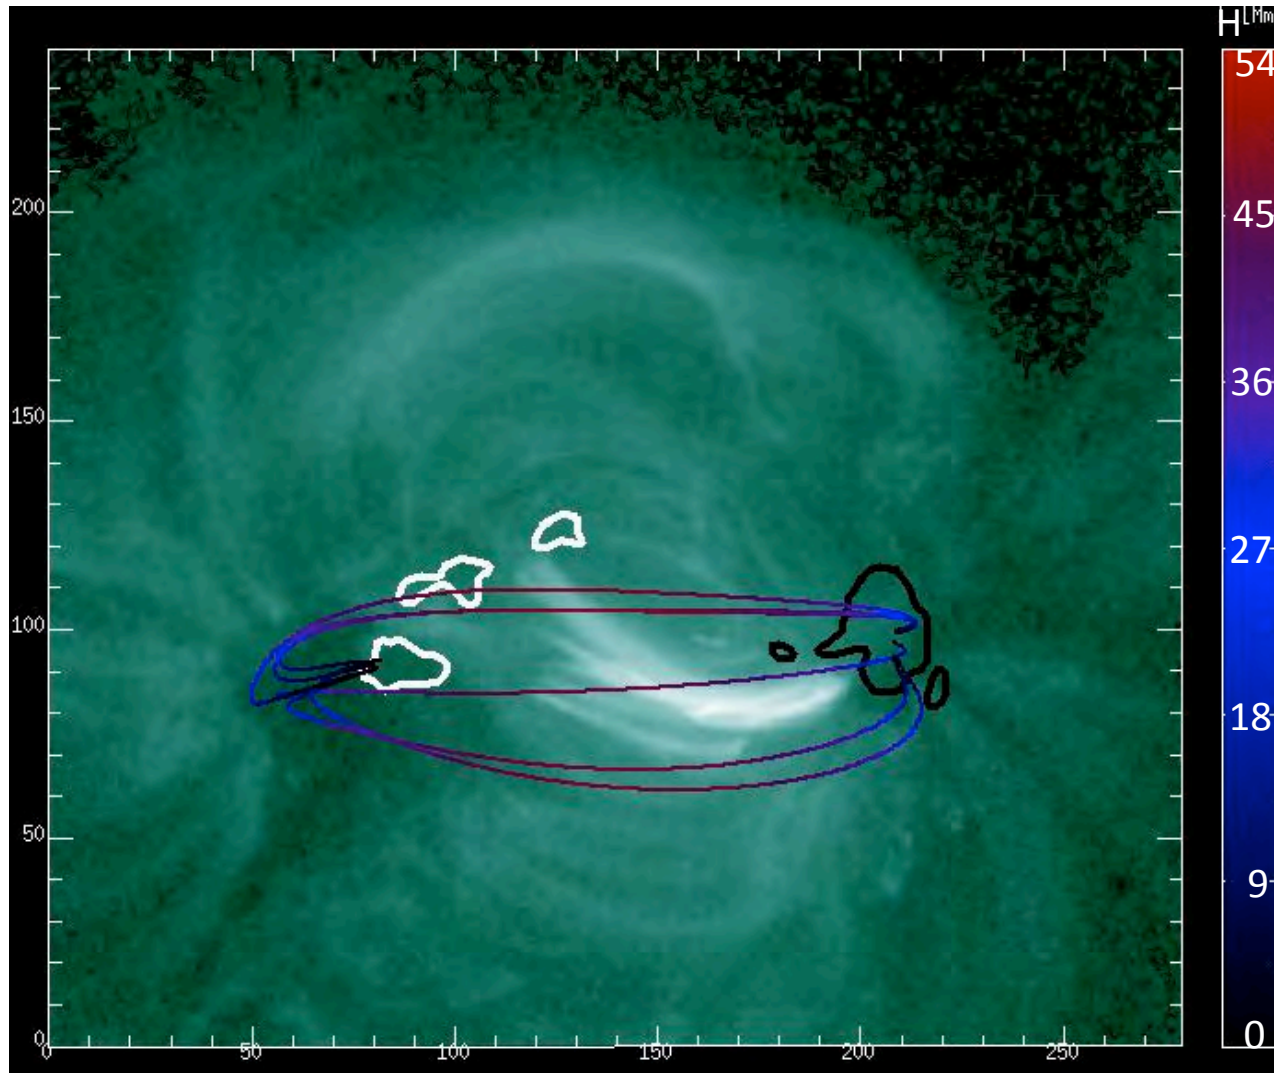

## Modeling results: high umbral loops

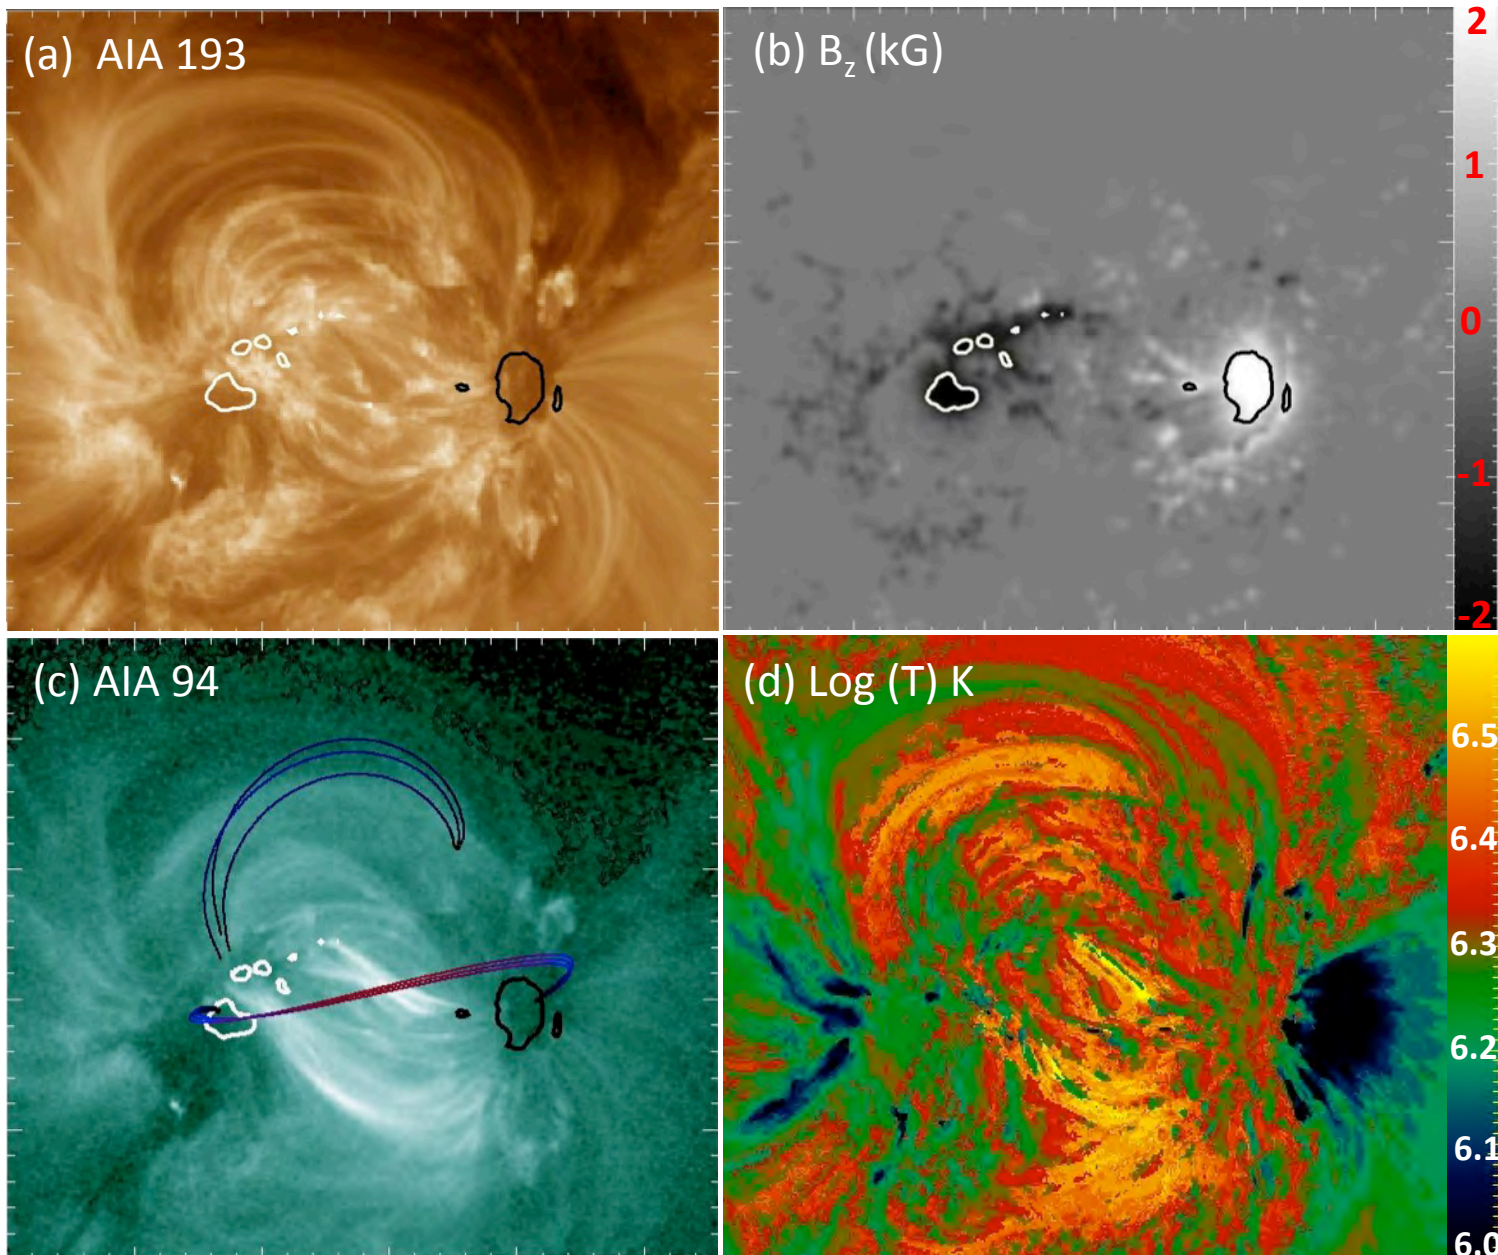

# Modeling results: lower umbral loops

# Example

07 Jul 2014 10:24 UT

## Summary of the preliminary results

- Lack of coronal emission in umbra-to-umbra loops is new evidence supporting Parker's idea that convection at loop footpoints drives coronal heating in ARs
- Most of the brightest loops are transient (micro/sub-flaring loops) and have the following magnetic rooting pattern:
  - AIA 94 Å umbra-to-umbra loops have the weakest heating
  - Plage-to-plage loops have intermediate heating
  - Umbra-to-plage/penumbra loops have the strongest heating

## Our hypothesis

**Magnetic field strength together with the convective freedom at the feet of the loops determines their coronal temperature**

- Umbra-to-umbra loops have the lowest temperature because they have least convective freedom at their feet, either to induce braiding in the coronal loops, or to generate Alfvén waves.
- Only umbra-to-plage and/or penumbra loops have the highest temperature because they have strong magnetic field and one of their feet has moderate convection
- Plage-to-plage loops have only intermediate temperature because they have rather weaker field, although they have moderate convective freedom at their feet

Loop length is important factor: work in progress!!

***Thanks!***
