The NASA STI Program Office . . . in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the lead center for NASA's scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA's institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counterpart of peer-reviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.
- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.
- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.
- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.
- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services that complement the STI Program Office's diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program Office, see the following:

Abstract

An airborne tool has been developed based on the concept that an aircraft maintain a time-based spacing interval from the preceding aircraft. The Advanced Terminal Area Approach Spacing (ATAAS) tool uses Automatic Dependent Surveillance-Broadcast (ADS-B) aircraft state data to compute a speed command for the ATAAS-equipped aircraft to obtain a required time interval behind another aircraft. The tool and candidate operational procedures were tested in a high-fidelity, full mission simulator with active airline subject pilots flying an arrival scenario by using three different modes for speed control. The primary objective of this study was to evaluate the concept from the standpoint of pilot acceptability and workload. A secondary objective was to validate the results of a prior Monte Carlo analysis of the ATAAS algorithm. Results showed that the aircraft was able to consistently achieve the target spacing interval within 1 s (the equivalent of approximately 220 ft at a final approach speed of 130 knots) when the ATAAS speed guidance was autothrottle-coupled and a slightly greater (4–5 s), but consistent interval with the pilot-controlled speed modes. The subject pilots generally rated the workload level with the ATAAS procedure as similar to that with standard procedures for a nominal Instrument Landing System (ILS) approach, and they also rated most aspects of the procedure highly in terms of acceptability. Although pilots indicated that the head-down time was slightly higher with ATAAS, eyetracker data showed only slight changes in instrument scan patterns and no significant change in the amount of time spent looking out the window with ATAAS, versus standard ILS procedures. Pilots also rated highly the acceptability of the amount of head-down time required to use the ATAAS tool.

1.0. Introduction

In recent years, air travel has increased at unprecedented rates, leading to traffic congestion in many of the nation's busiest terminal areas. With this trend expected to continue into the foreseeable future, many government and industry efforts have focused on research programs aimed at alleviating congestion through development of new procedures for airborne and ground-based use with supporting new technologies. To address this problem, the National Aeronautics and Space Administration's (NASA) Advanced Air Transportation Technologies (AATT) Project developed the concept of Distributed Air/Ground Air Traffic Management (DAG-TM). The DAG-TM concept involves various levels of collaboration between airborne and ground-based resources to enable less-restricted and more efficient aircraft trajectories throughout all phases of flight, leading to increased airport capacity.

The element of the DAG-TM concept that focuses on terminal area operations requires the development of procedures and technologies that allow aircraft to have more flexibility in choosing an efficient route through the terminal area, while arriving at the runway threshold properly and efficiently spaced from the preceding aircraft. The concept of Approach Spacing allows for a safe reduction in the excess spacing in traffic streams from what current procedures allow by increasing the precision with which aircraft are spaced, such that they can be delivered at the proper spacing interval at the runway threshold.

This precision requires the capability to accurately predict and control the spacing intervals between arriving aircraft. To meet this objective, an airborne tool, the Advanced Terminal Area Approach Spacing (ATAAS) tool, was recently developed at NASA's Langley Research Center (LaRC) (ref. 1). The ATAAS tool, a refinement of previous techniques, is based on previous work, which embodied the concept that an aircraft maintain a time-based, rather than distance-based, spacing interval from the preceding aircraft (refs. 2–5).

The ATAAS tool uses Automatic Dependent Surveillance-Broadcast (ADS-B) aircraft state data, along with final approach speeds and wind data, to compute speed commands that the ATAAS-equipped aircraft must follow to achieve the required runway-threshold time interval behind the other aircraft. This tool has undergone extensive Monte Carlo analysis to characterize and refine its performance. Although the tool has many potential applications in different types of operational scenarios, including merging routes, enroute, and oceanic operations, the concept of in-trail spacing in the terminal area (i.e., aircraft are spaced longitudinally while following directly behind each other on the same ground track) was the logical first step in the evolution of the end-state goal of more efficient and flexible maneuvering through the terminal area. Future plans for research in this area will address the merge problem, in which an aircraft arriving in the terminal area is sequenced behind an aircraft arriving from a different direction.

The ATAAS tool was tested with airline pilots in a high-fidelity, full mission engineering simulator to evaluate workload and pilot acceptability issues associated with its use and to explore the feasibility of the operational concept (i.e., can the assigned spacing interval be consistently achieved with the algorithm). This document describes the ATAAS tool, simulation test procedures, and presents the results of the test.

Documentation for these program concepts is available at these web sites:

NASA document: <http://www.as.nasa.gov/aatt/dagconop.pdf>

NASA contractor document: http://www.asc.nasa.gov/aatt/rto/RTOFinal41_4.pdf

2.0. Background

2.1. Past Work

Previous research has investigated the feasibility of using traffic information displayed on the flight deck to enable airborne-managed spacing (refs. 2–5). Simulator experiments conducted at LaRC that involve the use of Cockpit Display of Traffic Information (CDTI), including a display of the lead traffic's location and other predictors on the subject aircraft's Navigation Display (ND), found that time-based spacing was the most useful technique. A "time box" was used to represent the position where the subject aircraft ("ownship") should be. (The position of the time box on the ND provided a target for the ownship to achieve.) To be at the correct spacing interval (the spacing interval was assigned by Air Traffic Control (ATC)) behind the aircraft it was following, the ownship had to be positioned inside the time box. The studies concluded that this concept was feasible from a crew workload and acceptability standpoint, although accurate knowledge of the positions and speeds of the aircraft with fast data update rates are necessary. Recent improvements in display and computing capabilities and broadcast of traffic state data have made the concept realizable.

2.2. Approach Spacing Concept

The ultimate goal behind the in-trail approach spacing concept is not to optimize precision spacing for individual pairs of aircraft but rather to achieve a system-wide improvement in performance. That improvement will be realized by obtaining better consistency in spacing from a system-wide standpoint,

sometimes at the expense of having excessive spacing between individual aircraft pairs. As such, no single aircraft will receive guidance to aggressively achieve a spacing interval beyond what would normally be expected in current-day operations. Increasing the speed of one aircraft excessively to “close up the gap” with a preceding aircraft would quickly destabilize the system and would not increase system-wide performance. This destabilization could multiply the effect on the speed required of every aircraft that is in-trail, creating increasingly larger gaps and speeds well beyond acceptable levels by today’s standards. In future applications, any reduction in system throughput that could result from this type of limitation could be recovered through other methods, such as adjusting the lateral route in a designated maneuvering area. Flight crew procedures were developed to implement this in-trail concept with a focus on minimal effect to current workload levels.

Part of the Approach Spacing concept vision is the ability for unequipped aircraft (i.e., those without an ATAAS implementation) also to participate in this operation by means of a charted arrival. Including the nominal routing and speed profile as part of the charted arrival allows an aircraft that can maintain the charted profile to be cleared for and fly this arrival. By broadcasting its position and the appropriate data, it can also serve as a lead aircraft for the ATAAS-equipped aircraft sequenced behind it. This concept can also be extended to lower-density facilities as their traffic levels increase. The procedure allows aircraft to perform approach spacing operations at those facilities, enabling more consistent and reliable spacing of arrivals with minimal changes to infrastructure.

A fundamental issue that is unchanged from current-day procedures is the responsibility for maintaining separation between aircraft. With this new concept, responsibility remains with the Air Traffic Service Provider (ATSP). With this issue in mind, the clearance to conduct the approach-spacing operation is then a clearance to follow the ATAAS speeds. The clearance phraseology used for this study reflects this approach (see appendix A).

To develop the concept of in-trail, airborne-managed spacing in the terminal area, a nominal scenario was defined to include system and operational (crew and controller) procedures, with candidate phraseologies and a crew interface with the ATAAS tool. The concept includes the use of a charted Standard Terminal Arrival Route (STAR), similar to those currently in use today. The arrival route is extended to include a complete lateral path to the runway, plus a vertical profile (speed and altitude), all of which become part of the nominal arrival clearance. The nominal speed profile associated with this charted procedure provides a basis around which the ATAAS algorithm will build the speed commands the flight crew will use. The basic system procedure is the issuance of an additional clearance from the controller to the ATAAS-equipped aircraft flight crew, which identifies the traffic to follow (TTF) and the assigned time interval for spacing. This clearance could be issued at any time during the arrival. Once the flight crew accepts the spacing clearance and begins following the ATAAS-commanded speeds, no further speed clearances are needed from the Air Traffic Service Provider (ATSP), but other normal communications (i.e., frequency changes and approach and landing clearances) take place as usual.

Appropriate flight crew procedures were developed to allow interaction with the ATAAS tool, with minimal effect to current workload levels. Supporting display elements provide information to the crew on the ATAAS mode and the current state of the ATAAS-equipped aircraft (“ownship”) relative to the aircraft (the “lead” aircraft) it is spacing behind. A simple pilot interface with the ATAAS tool allows the crew to select the lead aircraft and enter other appropriate data (details of the interface, displays, and crew procedures used in this study are provided in the Method of Test section). In future applications, data-linked information could replace some of these required pilot interactions.

To test the ATAAS tool in a full-mission simulator, a nominal, in-trail arrival scenario was developed. Airline subject pilots were recruited to fly the simulator with ATAAS by using three different methods for controlling speed. Aircraft and ATAAS state and mode data were collected, pilot eye movements were

recorded, and pilots provided subjective ratings of perceived workload levels and various other aspects of the concept through questionnaires.

2.3. ATAAS Algorithm

The ATAAS algorithm is designed to provide pilots with speed guidance which, when properly followed, will result in the target spacing interval behind the lead aircraft at the runway threshold. Supporting pilot interface and display elements provide information on the mode of operation and the state of the ATAAS-equipped aircraft (“ownship”) relative to the aircraft it is spacing behind (the “lead” aircraft). To achieve the concept goals for system-wide efficiency, the ATAAS algorithm was developed with features and limits on the speed guidance it provides. Commanded speed will not exceed 10 percent of the nominal (charted) speed for any given segment on the arrival. Speed commands are also limited to prevent exceeding flap and landing gear limits. A more detailed description of the development of the ATAAS algorithm can be found in reference 1.

A trail of “history dots” behind the lead aircraft show its ground track on the ownship’s ND and can be used (flown manually) instead of an “area navigation” (RNAV) route for lateral navigation. A simple pilot interface with the ATAAS tool allows the crew to select the lead aircraft and to enter other appropriate data required for optimizing the ATAAS tool’s performance. The aircraft speed can be controlled to follow the ATAAS command speed automatically by engaging the tool directly connected to the autothrust system or with the pilot following the displayed command speed by making appropriate inputs to either the throttle levers or by dialing in the command speed in the Mode Control Panel (MCP) speed window. These three methods of speed control are referred to in this study as Automatic, Manual, and MCP, respectively. The speed guidance provided by the ATAAS system does not differ in any way for any of the methods of speed control used.

A feature of the ATAAS algorithm is its ability to provide a smooth transition from the commanded speed required for achieving the spacing interval to the final approach speed entered on the ATAAS Approach Data Control Display Unit (CDU) page by the flight crew. The algorithm is automatically switched to this approach mode near the final approach fix to allow enough time to achieve a stabilized final approach. When the algorithm makes a transition to this mode, it is no longer actively trying to maintain a spacing interval but rather is providing a scheduled speed reduction to the final approach speed selected by the flight crew.

A Monte Carlo analysis that uses the traffic distribution from a typical, high volume airport was conducted by using the ATAAS algorithm. The distribution of traffic only affected the final approach speed variable. To exclude multimodal effects of the minimum separation distances relative to aircraft categories, the minimum distance was set to 2.5 nmi.

The significant parameters used in the Monte Carlo analysis were the following:

- 50 aircraft in each arrival stream
- 100 arrival streams
- no winds
- a 2-s error (1-sigma) in the pilots’ response to a change in the speed command
- a 2-knot error (1-sigma) in the pilots’ speed command tracking performance

The nominal threshold crossing time was arbitrarily set to 93 s.

Based on the previous information, the significant results were as follows:

- (1) The average threshold crossing time was 94.04 s (an average of 1.04 s late).
- (2) The threshold crossing time error (1-sigma) was 2.49 s.
- (3) The minimum distance between aircraft pairs (1 aircraft pair in 5000) was 2.88 nm.

Although no winds were used in this analysis, additional variations in airspeed due to winds can have a significant effect on the arrival time if they are not adequately accounted for in the algorithm's computations. The inclusion of airport wind data as a pilot-entered piece of information can mitigate this effect, but a more effective solution would be to include wind data as part of the ADS-B data set.

3.0. Test Method

3.1. Facilities

3.1.1. *Flight Simulator*

The facility used for this experiment was the NASA LaRC Integration Flight Deck (IFD) simulator (fig. 1). The IFD simulator cab is an engineering cab designed to represent the conventional flight deck of the NASA ARIES (Airborne Research Integrated Experiments System) B-757 airplane. The cab is populated with flight instrumentation, including the overhead subsystems panels, to replicate the B-757. The cockpit contains a "Panorama" visual out-the-window display system. This system provides a 200° by 40° visual out-the-window display to add realism to piloted experiments.

Figure 1. NASA LaRC IFD simulator.

During these simulation tests, significant cockpit modifications included a nonstandard control panel for the ND, the addition of a page to the CDU, and minor format modifications to the Electronic Attitude Director Indicator (EADI). This nonstandard ND control panel was located on the aisle stand just aft of the throttles. The ND control panel contained a push-switch that activates the ATAAS system.

3.1.2. ATC Station

Air Traffic Control (ATC) communications were provided to the IFD during the experiment from a station located remotely from the simulator cab. The station had a display of air traffic and other information so that a single pseudo-controller could provide the real-time communications with other simulated traffic and the IFD cab. Pilots' headsets were used in the simulator cab to simulate radio communications.

A realistic communications environment was created through the activation of prerecorded sound files, which simulated transmissions from the other aircraft in the terminal area. The pseudo-controller could activate the appropriate sound file after issuing a clearance to an aircraft to simulate a response from that aircraft. Communications with the subject aircraft (simulator) were scripted, and the same spacing interval was used for all runs.

3.1.3. Eyetracker

Pilot gaze and eye movement data were recorded by using an eyetracker (ISCAN Model AA-ETL-500 low-level infrared, eye-tracking system and supporting software). The eyetracker weighed less than 8 oz and was mounted on a baseball cap. The wiring was bundled with the pilot's headset so that it did not interfere with the normal range of pilot head movement. Samples were obtained at 30 Hz. Fixations having a minimum duration of 100 ms within a 1-in. square area were recorded. A view of the instrument panel and windows and all the instruments and other areas of interest for eyetracker data were recorded on videotapes and through the eyetracker data collection software.

3.2. ATAAS Interface

Pilots obtained ATAAS guidance from the EADI and ND displays and the command airspeed bug on the airspeed indicator. Additional ATAAS status data and crew inputs were provided on Flight Management Computer (FMC) CDU pages. The ATAAS symbology on the EADI and ND appeared only after a lead aircraft and spacing interval were selected from the CDU page.

3.2.1. EADI Display

A conventional B-757 EADI display format, with a fast/slow (F/S) pointer and scale on the left side of the display format (fig. 2) was used for this experiment. Modifications were made on the F/S pointer and scale to provide ATAAS guidance to the crew. During the experiment, when ATAAS commands were not being generated for the crew, the F/S pointer and scale worked in the conventional manner by indicating a ± 10 -knot airspeed variance from the airspeed selected on the MCP and shown on the electromechanical Mach/airspeed indicator with the command airspeed bug (fig. 3).

When ATAAS guidance was provided to the crew, the F/S pointer and scale showed a ± 10 -knot speed variance from speeds commanded by the ATAAS algorithms. The pointer symbol format was changed to a green pentagon with the letter "P" in the middle to clearly indicate to the crew that it was driven relative to the ATAAS speed commands (fig. 4). Actual instantaneous ATAAS speed commands were displayed to the crew with the command airspeed bug on the Mach/airspeed indicator.

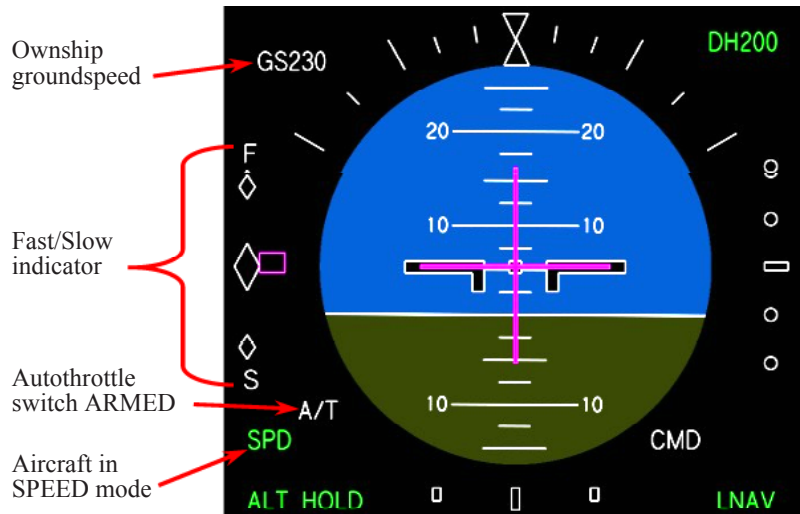

Figure 2. EADI with normal symbology (no ATAAS).

Figure 3. Mach/airspeed indicator.

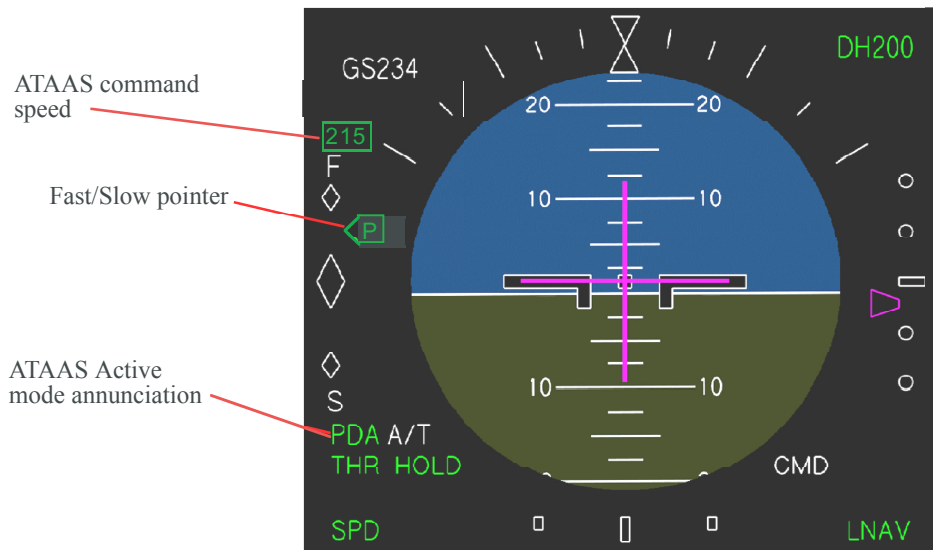

Figure 4. EADI with ATAAS symbology.

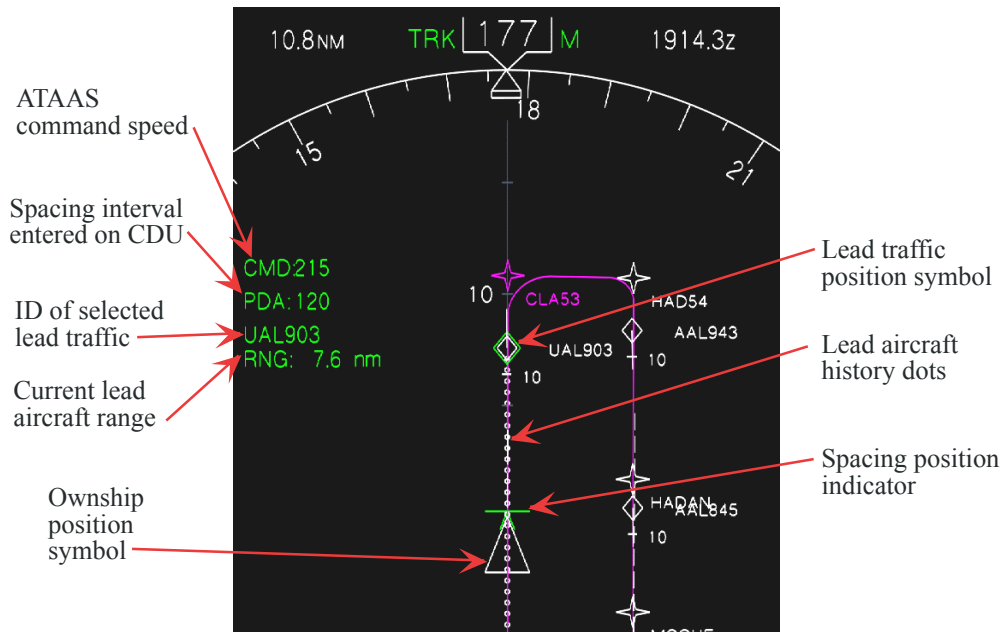

Figure 6. ND with ATAAS symbology.

The data block shows the commanded speed as the top line on the data block. This commanded speed is identical to the one that appears above the F/S pointer and scale on the EADI. Below the command speed in the ND data block is the spacing interval between ownship and the lead aircraft (in seconds) the call sign of lead aircraft, and the current along-track distance in nmi to the lead aircraft. The desired spacing interval (120 s in this example) and the call sign of the lead aircraft (UAL 903) are selected by the crew through the CDU. The data block updated automatically as the distance between the aircraft changed and also reflected any other changes (such as whether the pilots selected a new lead aircraft or spacing interval).

A spacing position indicator shows the position where the ownship should be to achieve the proper spacing interval (based on currently entered lead aircraft and desired spacing interval). This indicator is a short, green line perpendicular to the ownship's ground track, with an inverted "V" attached to the midpoint of the line. This indicator provides a visual reference of the ownship's position relative to the desired spacing interval. When the ownship is properly spaced, the spacing position indicator fits over the apex of the white triangular ownship symbol. If the spacing position indicator is behind the apex of the ownship symbol, the ownship is ahead of where it should be. Conversely, if the spacing position indicator is ahead of the ownship symbol, the ownship is behind where it should be.

The lead aircraft history dots (a trail of white dots extending behind the lead aircraft symbol) show the ground track of the currently selected lead aircraft. When an aircraft is initially selected as the lead, its history dots appear and instantly extend backwards past the ownship's current position, depicting the lead aircraft's ground track. This feature allows an ATAAS-equipped aircraft to maintain spacing behind an aircraft that is not on an RNAV route.

3.2.3. FMC-CDU Pages

Interface with the ATAAS system takes place through customized FMC-CDU pages, accessed through a function key on the CDU, labeled “ATC.” When this key is pushed, the Approach Spacing page appears with a list of the other aircraft in the terminal area on the right side of the page, in alphabetical order by call sign (fig. 7).

Figure 7. CDU Approach Spacing page before lead aircraft selection.

When the pilot line-selects the call sign for the lead aircraft, a block of data appears on the left side of the page showing the current actual spacing interval, the current actual distance between the lead aircraft and ownship, and the lead aircraft’s groundspeed. These data provide the crew a method to check the actual spacing against what was assigned, ensuring upon initialization of the system that there was agreement within some reasonable level (± 20 s of assigned interval). A prompt for entering the desired spacing interval will appear on Line Select Key 2 Right (LSK2R) on this page. Figure 8 shows that a 90-s spacing interval (for ownship to space 90 s behind the lead aircraft, UAL903) has been entered by the ownship crew.

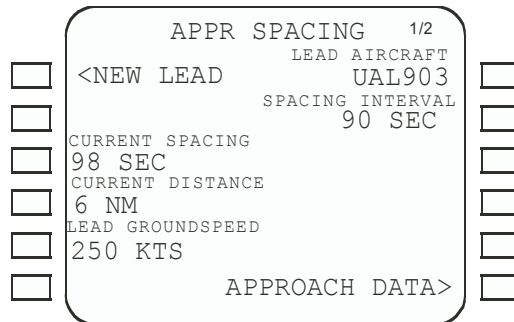

Figure 8. CDU Approach Spacing page after entering lead aircraft and time interval.

At the bottom of the page shown in figure 8 is a prompt on LSK6R that is labeled APPROACH DATA. Pushing this key displays the Approach Data page (fig. 9), which contains prompts for entering other relevant parameters, including final approach speed (FAS) for the ownship and the selected lead aircraft, minimum distance (if something other than wake-vortex separation is desired), and airport surface winds. For this experiment, data entry was only required for the FASs because the simulated environment was a calm day, and the standard separation was used. The values for FASs entered on this page are especially important on final approach when differences in speeds for the two aircraft could have a major effect on the spacing interval achieved at the runway threshold. The value for ownship FAS is the target speed used by the ATAAS algorithm when it transitions to approach mode.

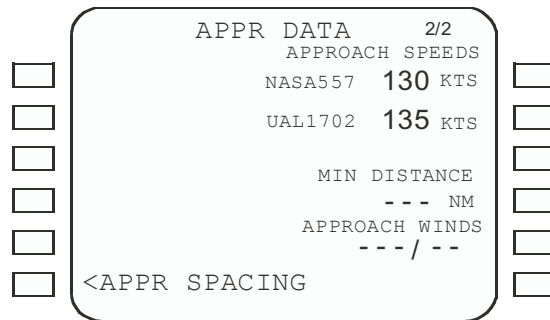

Figure 9. CDU Approach Data page after entering FASs.

3.3. Test Scenario

A single subject pilot was used for data collection, with a confederate pilot (member of experiment team) flying in the right seat. The confederate pilot was a retired airline pilot from a major air carrier and had previous experience as a participant in research studies at LaRC. Because crew interactions were not a focus of this study, this crew arrangement provided the opportunity to obtain data on acceptability and workload from the subject pilot while still maintaining the realism of operating in a two-person crew, full-mission environment.

The simulated environment for this study was the Memphis International Airport (MEM) and surrounding terminal area. Calm wind conditions and visibility of 10 mi in haze were simulated. The traffic level corresponded to what might be expected at a busy terminal area. Normal radio communications with ATC were provided. Other traffic in the pattern was generated from prerecorded tracks and was shown on the ownship displays and the out-the-window computer-generated imagery system.

The routing flown for the scenario was a modified WLDER4 STAR (fig. 10). Modifications to the STAR include a published downwind and base leg routing for a transition to the Instrument Landing System (ISL) runway 36 Right final approach course. The same flight scenario was used for all runs and began with the aircraft level at 8000 ft, 250-knot indicated airspeed (IAS), approximately 10 nmi prior to the downwind turn.

A single stream of arriving traffic was simulated and used for all runs (i.e., call signs of the aircraft in the arrival stream were the same for all runs). The subject aircraft (call sign “NASA 557”) was number 8 in the trail to the runway at the start of the scenario. The traffic aircraft (call sign UAL903) immediately ahead of NASA 557 and all other aircraft in the scenario followed the nominal charted speeds in an orderly manner, with no unusual or rapid changes in speed. The approach spacing clearance was issued after the aircraft had turned onto the downwind leg and switched the communication radios to the approach control frequency. The normal approach clearance was separate from the approach spacing clearance and was issued when the aircraft was on base leg. The assigned lead aircraft (traffic to follow) and spacing interval in the clearance were the same for all runs.

Eight different pilots participated in this experiment. Each pilot was scheduled to complete all briefing, training, and testing in one day. The morning started with a verbal briefing to supplement a copy of the flight manual bulletin and charts, which were previously mailed to the subject pilot. Included in the bulletin was background on the operation and the charted procedure, a summary of the procedures for interacting with the custom ATAAS FMC CDU pages, and a checklist indicating the crew member responsibilities for each step in the operation (see appendix A). All data runs were completed in the afternoon.

During the simulator training, each pilot received a short verbal briefing by the confederate pilot that covered differences between the simulator cab and a typical B-757 aircraft. Each test subject then flew three complete runs for training, one with each of the different methods of speed control used for following the ATAAS guidance. For the last of the three training runs, the subject pilot was fitted with the eyetracker equipment and a radio headset to demonstrate what the data runs would be like with radio communications and to obtain initial eyetracker calibration data.

Each pilot completed a test matrix of eight data runs (table 2). Each data run lasted approximately 20 min. A Latin Square design was used to order the runs to minimize the potential for interactions of the test variables. Calibration of the eyetracker and completion of a workload rating and a questionnaire following each run took approximately 10 min. Following completion of the last run, the subject pilot was taken back to the briefing room to complete the post-test questionnaire.

Table 2. Ordering of Runs for All Pilots

Condition number	Pilot 1 order	Pilot 2 order	Pilot 3 order	Pilot 4 order	Pilot 5 order	Pilot 6 order	Pilot 7 order	Pilot 8 order
1	1	6	8	3	7	5	2	4
2	5	2	4	1	6	8	3	7
3	2	4	1	6	8	3	7	5
4	3	7	5	2	4	1	6	8
5	6	8	3	7	5	2	4	1
6	8	3	7	5	2	4	1	6
7	4	1	6	8	3	7	5	2
8	7	5	2	4	1	6	8	3

3.3.2. Crew Procedures

During each run, the PNF was responsible for making inputs to the flight management system through the CDU, which included selecting the assigned traffic to follow, entering the assigned spacing interval, and any other necessary data (such as final approach speeds) on the ATAAS CDU pages. The PNF also acknowledged the clearance with ATC. The PF was responsible for activating the ATAAS system and following the speed commands. Both pilots were responsible for monitoring speed and other cues to ensure compliance with the speed commands. However, during this test, the confederate pilot did not advise the subject pilot when to adjust speed. These tasks were integrated with other normal duties. Each subject pilot acted as the PF in half the runs he completed and as the PNF in the other half.

The autopilot was engaged during all test runs. The autothrottles were engaged on all test runs except the ones in which manual throttle operations were required. All the ATAAS runs consisted of complete Flight Management System (FMS) routes that were flown in the lateral navigation (LNAV) mode for lateral guidance. The baseline runs were flown as they are currently flown in real-world operations, with

LNAV for lateral guidance until the end of the STAR, and then transitioning to the HEADING SELECT mode to comply with vectors from ATC. The pitch axis and throttle are integrated and included Altitude Hold (pitch controls altitude) and Speed (thrust controls airspeed) during level flight, and Speed (pitch controls airspeed) and Flight Level Change (thrust fixed at a constant setting, generally idle thrust) during descents. The Vertical Navigation (VNAV) flight mode was not used in this test. The descents were flown in Flight Level Change (FLCH) mode.

3.3.3. Subject Pilots

Eight subject pilots were used for data collection. The pilots were required to be type-rated and current in the B-757 aircraft. Total flight time for each pilot ranged between 4000 and 17 000 h. Two pilots had between 300–1000 h in type, and the remainder had over 1000 h in type. There were five first officers and three captains, from four different airlines. A summary of the subject pilot’s experience is shown in table 3.

Table 3. Summary of Subject Pilot Flying Experience

Pilot	Total flight hours	Hours in type (B757)	Current airline
A	6 200	>1000	CO (FO)
B	8 100	300–1000	AAL (FO)
C	10 000	>1000	UAL (C)
D	4 000	>1000	AAL (FO)
E	10 000	>1000	UAL (FO)
F	10 226	>1000	AAL (C)
G	4 000	300–1000	UAL (FO)
H	17 000	>1000	NWA (C)

3.3.4. Data Collection

Recorded data included aircraft state data from the simulator, data from the ATAAS system, and eye point-of-regard data from an eyetracker and headtracker. Aircraft state data included position, altitude time histories, and autoflight system mode. Data from the ATAAS system included the state in which the system was operating (i.e., armed, engaged, approach), in addition to the commanded speed and the time interval and distance between the ownship and lead aircraft. Eye point-of-regard data consisted of many positional parameters, which were used after the test to compute the two variables of primary importance: the dwell time (how long the pilot looked at a particular field of view each time he glanced at it) and the allocation of time on particular fields of view (i.e., for the duration of each test run and how the pilot’s attention was divided among the different fields of view, which are referred to as Areas of Interest (AOI).

Subjective data were obtained through questionnaires to solicit the pilots’ opinions on various issues related to using the ATAAS tool. Two structured questionnaires were administered, one following completion of each of the ATAAS runs (the Post-Run Questionnaire), and one at the end of the day, after completing all runs (the Post-Test Questionnaire). Using the NASA Task-Load Index (TLX) method (ref. 6), the pilots completed a workload self-assessment after each run. Copies of the questionnaires are included in appendix B, and a copy of the TLX is shown in appendix C.

4.0. Results

One goal of this study was to validate the results from the previous Monte Carlo analyses, which evaluated analytically the ATAAS algorithm’s ability to provide appropriate speed guidance to deliver the

aircraft at the runway with the proper spacing interval. In implementing the algorithm in the simulator, the system's performance becomes more dependent on the manner in which the guidance is followed and could have an effect on the spacing interval ultimately achieved. It is this difference, based on the method used for controlling the ATAAS speed to follow the ATAAS commands, that was explored in the data analysis for this study.

In the baseline scenario, the goal was not to try to achieve the same or similar results for interarrival spacing as in the ATAAS conditions because the controller's ability to space aircraft was not relevant. The baseline scenario was flown to provide the pilots a comparison for workload and acceptability ratings but was not a valid comparison for arrival time intervals because the traffic data were prerecorded and an actual facility controller was not used. Spacing intervals for the baseline runs were not computed. To make a valid comparison of spacing intervals achievable by a controller versus ATAAS, a separate test would be needed, with experimental controls appropriate to the different objectives of that test.

4.1. Arrival Time Interval

The time-based spacing interval between the lead aircraft and the subject aircraft was compared for all test runs in which ATAAS was used. This interval is the elapsed time from when the lead aircraft crosses the runway threshold until the following aircraft (the following aircraft is being flown by the subject pilots) crosses the threshold.

Figure 11 shows the mean and standard deviation of the time-based spacing interval at the runway threshold for all ATAAS runs. The results are presented by the method used for speed control as follows: Manual (pilot controlled speed by manually moving throttle levers, with auto throttles off); MCP (pilot controlled speed from MCP speed window); and Automatic (speed controlled by autothrottles coupled with ATAAS speed commands). The target spacing interval was 90 s for all runs. The Automatic condition resulted in the most accurate spacing, with mean intervals within 1 s of the target (standard deviation = 1.7) for both the PF and PNF positions. These results compare well with the Monte Carlo results, in which the mean error was slightly over 1 s, with a standard deviation of 2.49 s.

Figure 11. Spacing interval at runway threshold.

The lower end of the standard deviation is below 90 s, meaning that in some of these cases, the spacing interval at the runway was less than the assigned 90-s interval. Since the responsibility for maintaining a safe interval between the aircraft rests with the air traffic controller, the pilot is not required to initiate a go-around if the spacing interval falls below the assigned interval, as long as he continues to follow the ATAAS command speeds. With this implementation of the algorithm, the pilot did not have any indication of what the actual spacing interval was when ownship crossed the threshold because this information ceased to be displayed after the ATAAS algorithm transitioned to its approach mode.

The mean spacing interval errors for the Manual and MCP conditions were 4 s and 5 s late, respectively. Standard deviations for these conditions were comparable with the Automatic condition, both for PF and PNF positions. These results are consistent with expectations. In the Automatic condition, the aircraft is being controlled directly by the ATAAS speed command output, so it is expected that it would result in an interval close to the target. In the other two cases, the ATAAS algorithm is providing the same commands, but rather than a direct connection with the autothrottles, the aircraft speed is being controlled manually by the pilot. In these cases, the spacing interval error is subject to how closely the pilot controls the speed relative to the command speed.

This speed tracking performance is especially crucial during the final deceleration (in the final approach segment) and is the most significant factor in the performance differences among the three speed modes used in this study. A previous study showed that differences of 10–15 knots in final approach speed during the last 2 to 4 miles prior to the final approach fix (FAF) could cause differences on the order of 3–5 s (ref. 7) in actual versus predicted arrival time at the FAF. The effect that this type of error can have on the threshold arrival time cannot be corrected after the trailing aircraft has decelerated to FAS because the ATAAS algorithm is no longer computing a spacing interval from the lead aircraft.

The net effect of the pilots slowing down quicker than the scheduled ATAAS deceleration is a resulting spacing interval that is a few seconds longer than the target interval, as seen in figure 11. This case occurred in the Manual and MCP conditions, as shown in figure 11, as a result of the pilots' responses to the annunciated speed commands and could be mitigated by training or display changes that would encourage the pilots to follow the ATAAS speed guidance more closely. In figure 11, the higher standard deviation in the Automatic condition (with the subject pilot acting as PNF) was caused by a failure to enter the correct final approach speed for the lead aircraft, which resulted in a higher than normal spacing error at the threshold.

The ATAAS algorithm provided a means for achieving a target threshold interarrival time interval within a mean error of ± 5 s, which equates to approximately 1100 ft at the approach speed of 130 knots. Whether or not this performance level is adequate most likely depends on the specific traffic conditions and what level of throughput a facility is trying to achieve. In this study, it was found that the best results (± 1 s, equivalent to 220 ft) were achieved with closely controlled speed (i.e., speed was carefully controlled to precisely follow the ATAAS command speed), which was achievable with the ATAAS Autothrottle-coupled (the Automatic condition).

4.2. Pilot Interaction With Guidance

The number of times during each run that the ATAAS command speed changed was used as a factor to evaluate pilot acceptability, which gave an indication of the additional workload required when working with the ATAAS system. The route segment in which the number of speed changes was assessed started on the downwind leg where ownship was at 210 knots, descending from 8000 ft to 3000 ft. This

Table 4. Number of Commanded Speed Changes

	Mean	Standard deviation
PF Manual	7.3	1.3
PF MCP	7.5	1.5
PF Automatic	5.4	0.6
PNF Manual	6.4	1.3
PNF MCP	6.6	1.7
PNF Automatic	5.0	0.4

path segment ended at the final approach fix, where the ownship altitude was about 2300 ft mean sea level (MSL) and final approach speed was typically 135 knots (landing gear and flaps would be in a landing configuration).

The data summarized in table 4 reflect the number of times that the annunciated ATAAS speed command changed throughout the duration of each run. These data were obtained from videotape recordings of the primary instruments (EADI and ND) during the data runs. In a current-day type operation (using the Memphis arrival traffic area as an example), ATC would typically issue two or more speed reductions during this route segment plus the pilot-initiated deceleration to the final approach speed at the final approach fix.

The pilots in this study made more speed changes with ATAAS than are typically seen in the current-day environment. However, by making more frequent, but smaller speed changes, the more accurate an interarrival runway threshold spacing interval can be. Because the duration of each run was about 20 min, a change occurred, on average, about once every 2.5 to 3 min.

Comparing the conditions in table 4 across PF and PNF roles also shows that for the MCP and Manual conditions, when the subject pilot acted as PNF, there were fewer required changes in commanded speed observed. This result could be attributed to the confederate pilot's following the command speed more closely than did the subject pilots because the confederate pilot knew to more slowly follow the changes in the guidance. The confederate pilot had the same initial training as the subject pilots but had about 2 weeks more experience using the ATAAS system. The confederate pilot's higher performance level might be expected after having used the ATAAS system on a more frequent basis for a period of 2 weeks; however, a larger sample of data would be needed to more accurately quantify this effect.

The data in table 4 indicate that there were more speed changes required in the MCP and Manual conditions than in the Automatic condition. This result is not surprising because the autothrottles incrementally changed the speed to stay close to the ATAAS speed profile during speed reductions and resulted in fewer errors requiring correction. In the MCP and Manual conditions, the manner in which the pilots followed the speed guidance resulted in a greater number of required speed changes because of errors introduced when the ATAAS speed profile was not followed closely. Typically, these errors occurred when ATAAS commanded a large (greater than 10-knot) speed change, and the pilot dialed the MCP speed window or pulled the throttles back quickly enough to produce a greater deceleration rate than the ATAAS profile stipulates. Because the ATAAS deceleration rate was slower than that used in the simulator performance model (to make the ATAAS algorithm compatible with most aircraft types), the result was a steeper deceleration profile than the algorithm expected and often required a subsequent correction of about 5 knots. This effect can be seen by comparing data for a typical MCP condition run and a typical Automatic condition run.

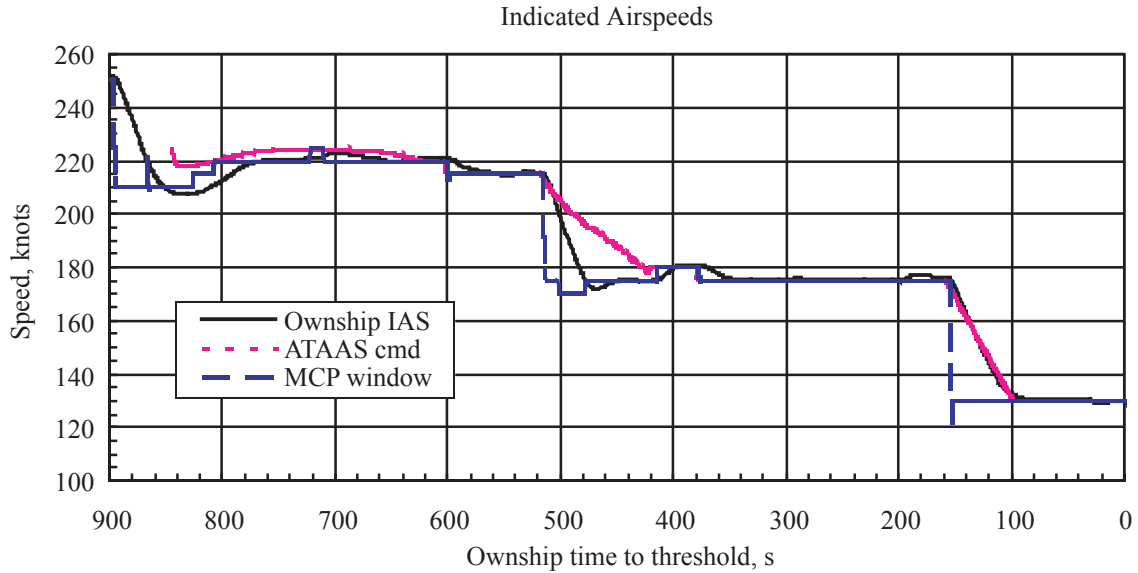

Figure 12(a). Time histories of ATAAS commanded speed, ownship indicated airspeed, and MCP window speed for MCP condition.

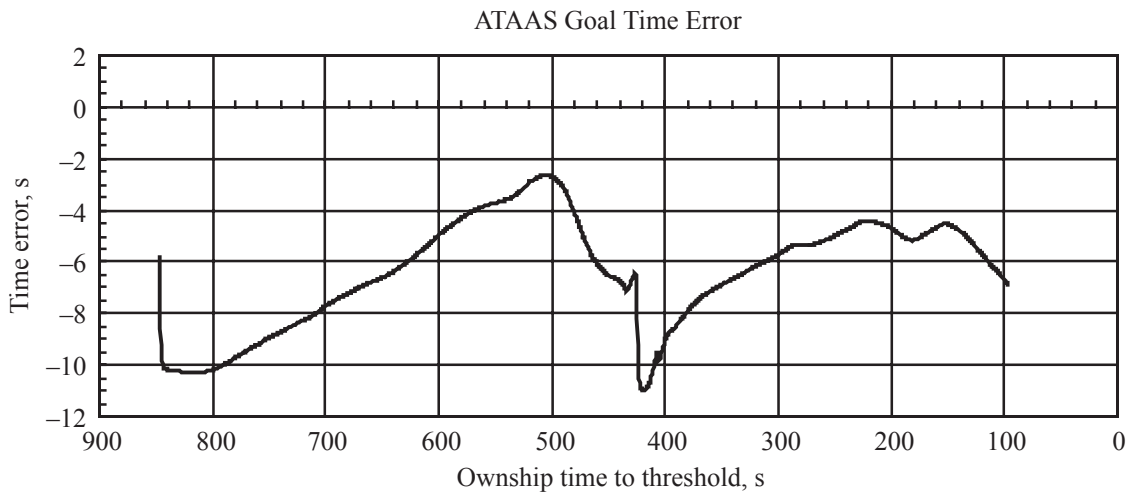

Figure 12(b). Accumulated time error (ATAAS predicted interval minus actual interval) for MCP condition.

Figure 12(a) shows time histories of three variables for an MCP test run: the ATAAS commanded speed, the ownship's actual indicated airspeed, and the speed dialed into the MCP window. Figure 12(b) shows the cumulative time error for the same data run. The time error is essentially the target spacing interval minus the current spacing interval. Figures 13(a) and (b) show the same plots for an autothrottle test run. The plotted data begin at the time the first valid commanded speed was displayed and end after the algorithm has transitioned to its Approach mode (and is no longer computing a spacing interval).

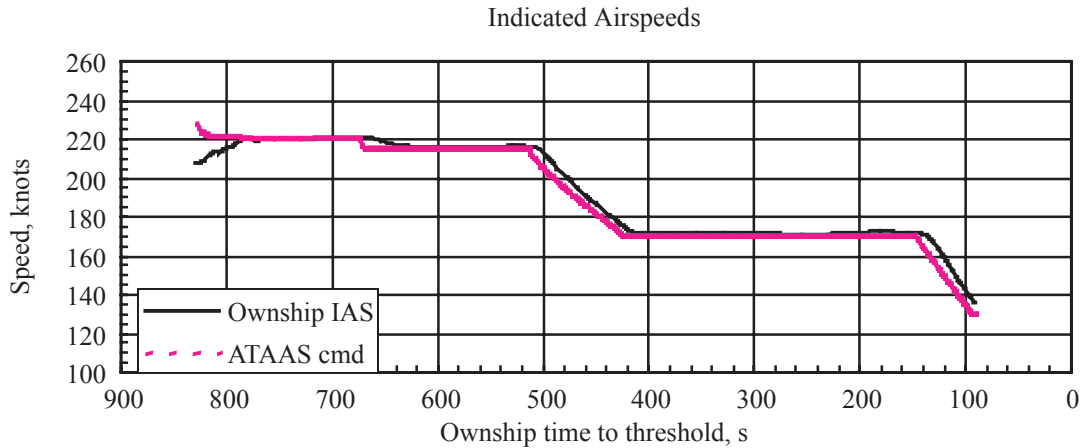

Figure 13(a). Time histories of ATAAS commanded speed, ownship indicated airspeed, and MCP window speed for autothrottle-coupled condition.

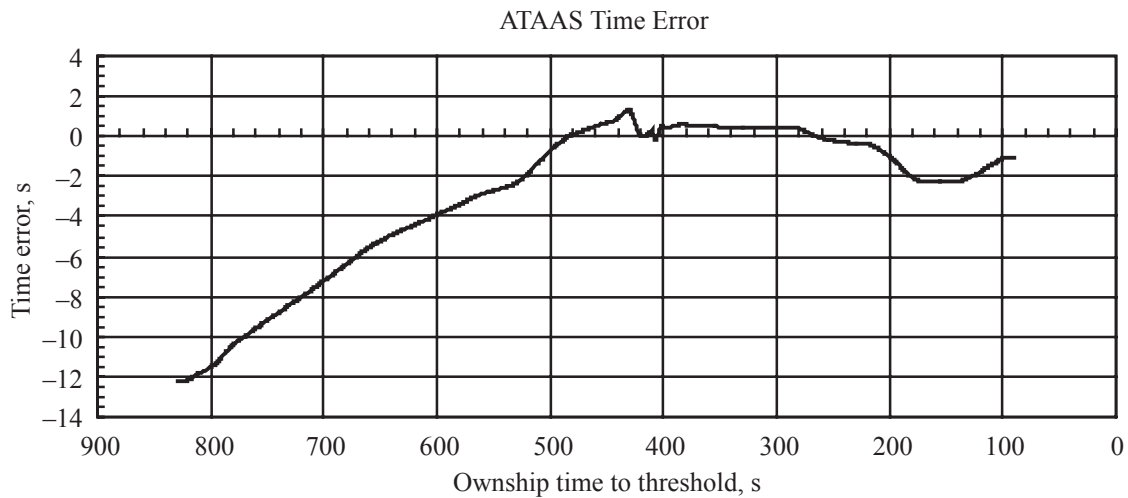

Figure 13(b). Accumulated time error (ATAAS predicted interval minus actual interval) for autothrottle-coupled condition.

At about $t = 510$ s, the ATAAS algorithm commanded a speed change from 215 knots to 170 knots. The deceleration profile used by the ATAAS algorithm shows a deceleration lasting about 100 s. The pilot dialed the MCP window speed quickly down to 170 knots, which initiated a deceleration that was faster than the ATAAS profile, as shown by the solid black line (ownship IAS). This deceleration lasted only about 50 s, leaving the ownship at the target speed much more quickly than predicted by the ATAAS algorithm. To compensate, the ATAAS algorithm then commanded another speed change back up to 180 knots for about 20 s (at $t = 420$) before finally returning to the original commanded speed of 170 knots. All pilots executed the speed changes in the MCP test runs in a similar manner.

This practice is typical of what most pilots do in the current-day environment. When ATC issues a speed change, the pilot typically dials the MCP window speed quickly to the assigned speed, letting the aircraft slow at its own rate, rather than trying to follow a deceleration schedule. To avoid the need for

corrections (as illustrated in this example) would require the pilots to be able to follow the ATAAS command speed more closely. This ability would require changes to the ATAAS display elements that would allow the pilot to follow the ATAAS deceleration profile or to receive additional training for the pilots on what the deceleration profile used by the ATAAS algorithm looks like.

The effect on the spacing interval can be seen clearly in figure 12(b), as the error is at about -3 s and is approaching zero at $t = 520$ s (when the speed change is initiated) but then begins to depart again as the aircraft slows down more quickly than predicted by the ATAAS algorithm. After the ATAAS command speed correction, the error again begins to dissipate towards zero. This effect is seen again on a smaller scale just before the lead aircraft crosses the threshold when the ownship begins to slow to approach speed. The large error at the start of the data is a transient from the initialization of the algorithm and was evident in all the data runs. This transient did not affect the spacing interval results because it dissipated with plenty of time to allow fine-tuning of the spacing interval, regardless of the method used for speed control.

In figure 13(a), the ATAAS command speed profile is seen leading the ownship IAS by a few seconds, showing the close coupling between the ATAAS deceleration profile and the ownship speed when the autothrottle guidance follows the ATAAS command speed (in the Automatic test runs). This type of behavior was seen in all Automatic test runs. Because the speed control task did not involve interaction from the pilots, there were no pilot-specific differences. The effect on spacing interval error can be seen in figure 13(b), in which the time error remains within ± 2 s throughout most of the latter half of the run.

4.3. Eyetracker Results

An eyetracker recorded the subject pilots' eye movements to ascertain that the introduction of the ATAAS tool on the flight deck was not detrimental to the pilots' out-the-window scan. It was noted during the data collection that all pilots attempted to see the other traffic that was visible out the window. The eye movement results of this study address issues related to the effect of ATAAS on pilot visual attention and can offer objective support for pilot judgments of ATAAS acceptability under the varying levels of automation. The complete analysis results are published separately (ref. 8). A summary of the results pertaining to differences in out-the-window scan attributed to the use of ATAAS are presented in this section.

The dwell or duration of fixations was defined as the time between entering and exiting an area of interest (AOI). The following AOIs were defined, as shown in figure 14: (1) EADI, (2) ND, (3) Airspeed Indicator, (4) Altimeter, (5) MCP, (6) Window, (7) Left side CDU, (8) instruments on the right side, and (9) Right side CDU.

4.3.1. Eyetracker Data Analysis

Prior to analysis, data were segmented through review of the eyetracker videotapes into sets labeled "Downwind" and "Final Approach." The Downwind segment comprised the period from the start of the run to completion of the turn onto the base leg of the arrival pattern (but not including the full base leg). Final Approach started with transmission of the Final Approach clearance as the aircraft began to turn onto the Final Approach leg and concluded with touchdown.

Figure 14. Definition of eyetracker AOIs.

4.3.2. Pilot Scan Pattern

The effect of ATAAS on pilots' visual scan patterns was examined through a link analysis, a method of assessing the pattern of how a person's gaze transitions from one area of interest to another, such as from the EADI to the airspeed indicator. Link values represent the percentage of unidirectional eye movements between defined AOIs (i.e., movement from one AOI to another). The link analysis was conducted separately on the Downwind and Final Approach data sets. Comparisons were made among all ATAAS conditions and the Baseline condition, and also between each of the ATAAS conditions to examine the effect of ATAAS in conjunction with the different methods of speed control.

Overall, the pilots' scans did not appear to exhibit a definable sequence of eye movements from one AOI to another because the link values were nearly equivalent in either direction—equally true of both ATAAS and baseline conditions. The strongest link in nearly all conditions was from EADI to Airspeed, which was expected, since the additional task required with the use of ATAAS is to follow the airspeed. This increase was higher in all ATAAS conditions than in the comparable (PF or PNF) baseline conditions for both the Downwind and Final Approach flight segments. However, the difference was only 1 or 2 percent, which is not a significant change. The introduction of ATAAS did not result in any pilot eye scans between instruments that were different from those recorded for the Baseline conditions.

4.3.3. Allocation of Visual Attention

The pilots' allocation of visual attention is inferred from the proportional distribution of dwell time, that is, the proportion of simulation run time in each flight segment (Downwind or Final Approach) that the pilot's gaze remained within an area of interest. An 8×8 within subjects Analysis of Variance (ANOVA) was conducted on percent dwell time by Condition, Subject, and Run for each of the seven AOIs. For this study, the AOI of prime concern was what effect the ATAAS command and pilot tasks have upon the out-the-window eye scan.

An analysis was conducted to determine whether there were statistically significant differences in the effects upon the out-the-window scan caused by the differences in the test conditions, differences among the pilots, and the order in which the test runs were conducted. In the downwind segment, no significant effects were found for the allocation of attention to the window AOI, although there were significant effects for other AOIs. For the Final Approach segment, the ANOVA conducted on proportion of time allocated to the Window AOI showed significant differences among test conditions. The amount of attention given to the Window was significantly higher in PF Auto (18 percent) than in PF Manual (10 percent), which was expected, because the pilot has more time to look out the window when he does not have to manually control the speed.

4.3.4. Dwell Time

Dwell time is the length of time that the pilot's gaze remained within an AOI without moving outside of that area. The analysis performed on dwell time was the same as in the preceding section for allocation.

The mean dwell time for pilots looking out the window was greater on the final approach segment than on downwind for all test conditions. This result was expected because the pilots had visual reference to the runway on which they were landing. For the downwind segment, the Manual and MCP conditions showed lower mean dwell times than the Baseline condition, and Automatic showed higher mean dwell times, meaning that the pilots had less time to dwell on looking out the window during the Manual and MCP conditions than during the Baseline condition, and more time during the Automatic condition than during the Baseline condition. However, on final approach, a different effect is seen, with longer dwell times for the Manual and MCP conditions than Baseline and slightly higher dwell times for the Automatic condition versus Baseline. The dwell times for the Automatic condition are very similar to the Baseline condition, with slightly higher variation.

4.3.5. Summary of Eyetracker Results

The effects of the ATAAS guidance were analyzed through comparisons between the MCP and Baseline conditions because for these two conditions, speed changes were made in the same manner (the pilot dialed the desired speed into the MCP speed window). Few differences in visual attention were found that could clearly be attributed to ATAAS. The only statistically significant effect was that the percentage allocation of attention to the MCP was significantly greater (by 4 percent) in PF MCP than in PF Baseline during the Final Approach flight segment. This effect was most likely due to a greater number of speed changes during this segment on ATAAS runs versus baseline runs. No significant differences in dwell time were found in comparisons between the PF MCP or PNF MCP and the comparable Baseline conditions in either the Downwind or Final Approach data sets, indicating that the pilots' scans were not changed significantly by the addition of the ATAAS tool. Also, few differences in pilot scan patterns were evident. Small decreases in eye movements from all instruments to the Window can also be attributed to ATAAS (indicating that less time was available to spend looking out the window), but none of the individual links decreased by more than 1 percent. In all, ATAAS reduced eye movements to the Window by 3 percent during Downwind and by 2 percent during Final Approach.

4.4. Workload Results

4.4.1. TLX Workload Estimates

The NASA Task-Load Index (TLX) method (ref. 6) was used to obtain a perceived workload rating from each test subject after each test run. The NASA TLX is a multidimensional workload rating scale that uses six different dimensions to assess a test subject's perceived workload when performing a given

task. For the current study, each dimension of the TLX rating was scored on a scale with a range from 0 (low difficulty/demand) to 20 (high difficulty/demand). The six TLX scales used for rating the workload (Mental Demand, Physical Demand, Temporal Demand, Effort, Performance, and Frustration) are described in appendix D. The TLX measure was a composite created by averaging the six TLX scale values for each participant. The composite score was used because the individual TLX scales were highly correlated with one another and thus provided redundant information. A 2 x 4 [(Pilot Position: Flying, Not Flying) by (Condition: Baseline, Automatic, MCP, Manual)] within subjects ANOVA on the TLX workload estimates showed a significant difference in reported workload for pilot position, $F(1, 7) = 7.80$, $p < .05$. As expected, flying the aircraft (Mean (M) = 14.68, Standard Deviation (SD) = 10.55) elicited higher workload estimates than not flying the aircraft (M = 9.60, SD = 6.04). No significant differences were found for condition, $F(3, 21) = 1.82$, $p > .05$. Thus, none of the methods of speed control that were used differed significantly from the baseline workload estimates or from one another (see fig. 15). This result indicates that the pilots did not perceive a significant increase in workload while using the ATAAS system compared with standard procedures. The speed control methods used for following the ATAAS commands covered three different levels of pilot involvement in adjusting aircraft speed. Even with the additional piloting task required to follow the ATAAS commands, plus the additional CDU interface required for setting up the ATAAS system, the workload level perceived by the pilots did not show statistically significant differences from baseline conditions.

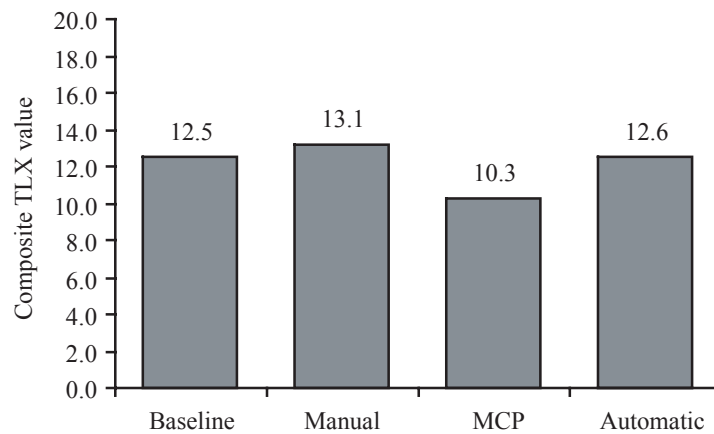

Figure 15. Mean TLX workload estimates (PF) for each condition.

4.4.2. Post-Run Workload Questionnaire

The post-run questionnaire had the participants compare their level of mental, physical, and overall workload produced by the task to the workload level for a standard (non-ATAAS) approach. The responses for these scales correlated very highly with one another (table 5) and were combined into a

Table 5. Pearson Correlations Among Post-Run Workload Comparisons

	Physical	Mental	Overall
Physical		.71*	.82*
Mental	.71*		.86*
Overall	.82*	.86*	

* $p < .05$

Figure 16. Mean post-run workload comparisons for mode as function of pilot position.

single composite workload measure by averaging the three scores for each participant. A 2 x 3 [(Pilot Position: Flying, Not Flying) by (Mode: Automatic, MCP, Manual)] within subjects ANOVA on the composite workload scores showed no significant differences for any of the effects. Because the questionnaire asked the pilots to compare the ATAAS conditions with the Baseline, the questionnaire was not administered for the Baseline conditions.

Figure 16 illustrates the post-run composite workload comparisons for the experimental conditions. The scores were adjusted to illustrate perceived workload comparisons relative to nominal ILS approach procedures. Positive values for an experimental condition indicate higher workload than a nominal ILS approach procedure, while negative values indicate lower workload (values for the comparisons were between -3 and 3). Note that the original scale was from 1 to 7; the adjustment to a scale of -3 to +3 was done for better visualization of differences in the figure, while preserving a 7-point scale.

Table 6 shows that the workload estimates given for the TLX appear to correlate well with the workload comparisons given for the post-run questionnaire. These correlations serve as a rough reliability check and confirm that the mental and physical scales of the TLX are significantly correlated with the mental and physical scales of the post-run questionnaire, respectively.

Table 6. Pearson Correlations Between TLX Scales and Post-Run Workload Comparisons

	Physical workload (post-run)	Mental workload (post-run)	Overall workload (post-run)

TLX Frustration	.151	.335*	.241

*p < .05

4.5. Post-Run Questionnaire

4.5.1. Overall Acceptability

Pilot acceptability ratings for the ATAAS tool were examined separately for downwind, base, and final approach segments from questions that used a 7-point scale (1 = not at all acceptable, 4 = borderline, and 7 = very acceptable). Pilots responded to the question, “How acceptable was the ATAAS tool during the following phases of the approach procedure?”

A separate 2 x 3 [(Pilot Position: Flying, Not Flying) by (Condition: Automatic, MCP, Manual)] within subjects ANOVA was performed on each approach segment and showed no significant differences for any of the effects. The means for overall ratings of acceptability for the ATAAS tool, across all conditions, were quite high, as can be seen in table 7. These results indicated an overall acceptability of the ATAAS tool by the subject pilots.

Table 7. Mean Overall Acceptability of ATAAS Tool by Flight Segment Across All Conditions

Phase of approach	Mean	Standard deviation
Downwind	6.38	.96
Base	6.62	.53
Final	6.49	.66

4.5.2. Acceptability of Head-Down Time

The acceptability of the amount of head-down time was examined with the question, “How acceptable was the amount of head-down time for the following phases of the approach procedure?” A 2 x 3 [(Pilot Position: Flying, Not Flying) by (Condition: Automatic, MCP, Manual)] within subjects ANOVA showed no significant differences for any effects for any of the phases of approach (downwind, base, final). Subject pilots across all conditions rated the amount of head-down time quite acceptable (table 8).

Table 8. Mean Acceptability of Head-Down Time Across All Conditions

Phase of approach	Mean	Standard deviation
Downwind	6.00	1.37
Base	6.23	1.07
Final	6.38	.80

4.5.3. Confidence With the ATAAS Tool

Confidence ratings with the ATAAS tool’s guidance were examined by using a 7-point scale (1 = not at all confident, 4 = borderline, and 7 = very confident). Participants responded to the question, “How confident were you with the guidance provided by the ATAAS tool during the following phases of the approach procedure?” A 2 x 3 [(Pilot Position: Flying, Not Flying) by (Condition: Automatic, MCP, Manual)] within subjects ANOVA on the confidence ratings was performed on each phase of approach (downwind, base, and final). No significant effects were found in any of the three ANOVAs. Participants across all conditions rated their level of confidence quite high for all phases of the approach (table 9).

Table 9. Mean Confidence in Guidance Provided by ATAAS Tool
Across All Conditions

Phase of approach	Mean	Standard deviation
Downwind	6.35	1.06
Base	6.64	.57
Final	6.62	.58

The statistical power (a result of the observed power calculated in the ANOVAs performed on the workload data) in all of the previously described analyses was too low to detect any true differences among the conditions.

4.6. Post-Experiment Questionnaire

The Post-Experiment Questionnaire was divided into the following sections: Acceptability, Procedures, Flight Management Computer-Control/Display Unit, Navigation Display, Electronic Attitude Director Indicator, Training, and Comments. Selected questions from each of the sections are included in the discussion to give a picture of the overall pilot opinions. The questions that required selecting a rating used a seven-point scale, in which the descriptors for the midpoint (4) indicated neutral conditions (i.e., borderline, unchanged, or moderate). Descriptors for the high end of the scale (7) indicated the more desirable condition (i.e., completely effective, completely comfortable, extremely clear, and very easy), and for the low end (1) were the more undesirable conditions (i.e., completely ineffective, completely uncomfortable, extremely unclear, and very difficult). Responses to these questions are summarized in table 10 as means and standard deviations. The pilots were also free to insert comments to help clarify their responses. In addition to these questions, a number of open-ended, essay-type questions were asked. The more common or significant pilot responses to these questions are also summarized in the discussion.

4.6.1. Acceptability

The pilots gave high ratings to the Approach Spacing concept in all questions (Qs) in the Acceptability section. Generally, they answered that they were comfortable using the ATAAS tool to maintain the assigned spacing in the terminal area (Question 1), and that it was effective in helping maintain the assigned spacing (Q2). The pilots' perception of level of safety was that it was slightly enhanced when using the ATAAS tool over nominal ILS approach procedures (Q3). The pilots also responded that the approach spacing procedures and tools could be effectively integrated into the current flight deck operational environment (Q7), and that they had confidence in the speed guidance provided by the tool (Q4).

The subject pilots were also asked if they could think of any real-world situations in which the ATAAS procedures and tools might not be effective. The most common responses were in adverse weather conditions that required deviations and in gusty wind conditions. Two pilots mentioned that variations in speed control of the lead aircraft could possibly cause a ripple effect on all following aircraft, and one pilot mentioned the airspace limitations as a potential problem. One pilot also mentioned, as a possible problem, a "last minute" insertion of an aircraft into the flow.

4.6.2. Procedures

The subject pilots gave high ratings to the overall procedure for using the ATAAS guidance system (Q9), as well as the clarity of the phraseology used for the approach spacing clearance (Q11). The subject pilots indicated how comfortable they were accepting the assigned spacing interval (Q12). When asked to

Table 10. Summary of Post-Experiment Questionnaire Responses

Section	Question	Mean	Standard deviation
Acceptability			
	Q1	6.19	.65
	Q2	6.31	.46
	Q3	5.44	1.40
	Q4	5.94	.86
	Q5	5.56	.62
	Q6	5.63	1.19
Procedures	Q7	6.13	.83
	Q9	6.38	.74
	Q10	6.38	.92
	Q11	6.38	1.06
	Q12A	6.50	.53
FMC-CDU	Q13	3.00	.93
	Q15	6.75	.46
	Q16	6.75	.46
	Q17	6.00	1.83
	Q18	6.63	.52
	Q19	6.50	.53
	Q20	6.38	.52
Navigation display	Q21	6.38	.74
	Q24	5.06	1.66
	Q26	6.25	.71
	Q27	6.00	.76
	Q29	6.00	.93
EADI	Q30	6.13	.64
	Q35	4.50	1.69
	Q36	5.75	1.04
	Q37	6.13	.83
Training	Q38	6.31	.80
	Q41	6.25	.71
	Q42	2.50	1.77
	Q43	3.38	1.60
	Q44	5.00	1.85

compare the amount of time spent looking at displays for the approach spacing procedure with the amount of time spent looking at displays with standard procedures, the responses indicated that it was slightly higher for the ATAAS approach spacing procedure (Q13). None of the pilots made any comments that an unacceptable level of head-down time was required when using the ATAAS commands.

4.6.3. Flight Management Computer-Control Display Unit (FMC-CDU)

The subject pilots were asked how well the CDU ATAAS pages provided clear (i.e., unambiguous) and consistent labeling, and the responses indicated that they found the information to be very clear

(Q16). The methods for selecting the lead aircraft and for entering the spacing interval were also rated highly for adequacy (Q18 and Q19, respectively), as was the acceptability of the amount of time spent working with the CDU ATAAS pages (Q21).

When asked which piece of information they would add to the CDU pages, only half the pilots responded, and no single item of significance stood out (Q22). When asked which piece of information they would remove from the CDU pages (Q23), two pilots responded that surface winds would likely be “out of date” by the time they got to the outer marker, and were too dynamic to be useful, and therefore not necessary.

One pilot commented that the actual time interval displayed on the Approach Spacing page seemed to lag and sometimes seemed to contradict the commanded speed. To understand why these two pieces of information sometimes did not appear to be in agreement requires an in-depth understanding of how the ATAAS algorithm computes these parameters. For a pilot who might not be very familiar with the system, this “apparent” inconsistency could lead to believing that these two sources of information were conflicting. Since the actual clearance from ATC is to “follow ATAAS speeds,” and the crew is not required to actually maintain a given time interval, the spacing interval at any time is not a necessary piece of information for the pilots to have. In a data link environment, it would not be necessary for the pilots to manually enter data through the CDU. The identification and final approach speed of the aircraft to follow, and the spacing interval to maintain would be uplinked, which would lower the workload for the nonflying pilot.

4.6.4. Navigation Display

The subject pilots were asked how effective the “spacing position indicator” was in communicating whether they were fast or slow, relative to the lead aircraft (Q24). The mean value for this question indicated that the subject pilots judged this display symbology to be slightly effective, but the high standard deviation indicated that there was wide variation in opinions among the subject pilots. When asked to comment on its effectiveness, the responses were also varied. These comments about the effectiveness of the spacing position indicator were positive: it provided excellent situation awareness; the pilot relied on it for “proof” that the system was working; it was a very good, clear symbol; it was a better indicator of relative position than closure or separation. Other pilots indicated that they could have flown without it, and it was only included in their instrument scan at a low level.

All subject pilots gave high ratings to the effectiveness of the commanded speed in communicating whether the ownship was fast or slow relative to the lead aircraft (Q26), and the “flashing box” used to communicate a speed change (Q29), although one pilot commented that it should be bigger to avoid confusion with ground speed. Most pilots also gave high ratings for the effectiveness of the green outline used to highlight the lead aircraft symbol (Q27). Two additional comments were received, one stating that it might pose a problem with a lot of green from weather radar in the background. Another commented that it would be better to display the lead aircraft speed under its call sign to make it easier to determine the relative speed.

High ratings were given for the acceptability of the amount of symbology on the display (Q30), indicating that they did not consider it cluttered. When asked what information they would add to the display, three pilots asked for the speed of the lead aircraft, two for the actual time in-trail, and one for wind data. When asked what information they would remove from the display, two pilots indicated that they would remove the spacing interval target (because it is the target speed only; in a nominal case, it does not change unless the spacing clearance changes), and one pilot mentioned the spacing position indicator.

4.6.5. Electronic Attitude Director Indicator (EADI)

The pilots were asked to rate the effectiveness of the F/S Indicator on the EADI in communicating the relative speed of the two aircraft. The mean value for this question indicated that the subject pilots judged this display symbology to be borderline effective, but the high standard deviation indicated that there was much variation among the ratings. One pilot commented that he thought it had some “glitches.” When asked which piece of symbology they would remove, two pilots mentioned the F/S Indicator.

Most pilots rated the effectiveness of the commanded speed (above the F/S Indicator) considerably higher (Q36, $M = 5.8$, $SD = 1.0$), with only one “borderline” rating, and the rest rated it higher. Two of the pilots indicated that they would like to see the commanded speed blink longer, and one of them suggested it blink until the speed was changed.

4.6.6. Training

The subject pilots gave high ratings to the effectiveness of the training received. They indicated that they did not think ATAAS training could be accomplished with only paper or video instructions or without practice in a high-fidelity simulator. When asked specifically what would be the minimum training needed to accomplish the task, most pilots indicated that they at least wanted video or computer-based (interactive) training. More than half also said they would include fixed-base or procedures simulator training. The amount of display symbology (Q37) and the effectiveness of the symbology annunciating the current mode of operation (Q38) were both judged by the subject pilots as very effective.

4.6.7. General Comments

This section summarizes some of the general written comments from the subject pilots.

“Overall really liked the concept; but I think more time should be spent during pre-brief on the subject of mode switching, capture logic.” (This pilot also had questions about ATC acceptance/notification of speeds higher than the profile speed.)

“...felt that there was a great increase in flight crew situation awareness, and system would provide for much more accurate speed and in-trail spacing planning...” (this pilot also noted that he hoped the program would be fully implemented, with RNAV arrivals that have hard airspeed and altitude restrictions).

One pilot suggested making data input (on CDU) a 2-step procedure (concur-execute), and was concerned that the other pilot might not catch an error.

Pilot was somewhat confused with paper-only information until he saw it in action, but then thought it was “...a great tool and should be used.”

Pilot commented that the “system would require minimal training from a pilot’s viewpoint...” and “thought ATAAS was very user friendly.”

Pilot thought that “the program was right on target.” Pilot also commented that you need to “integrate the ATC clearances without reinventing” the procedures.

Pilot suggested that the flashing box around the newly commanded airspeed could remain flashing until the MCP speed was moved to match, thus ensuring the change didn’t occur while the crew’s attention is diverted. He also suggested including flap speed protection.

Another pilot thought the concept and software were good, but expressed doubts about how the system would operate in the real world with “6 or 12 aircraft changing speeds at various rates.” This pilot also expressed concern about having speed protection as the flap configuration changes, and suggested that the MCP speed window should blank during the Automatic mode. Pilot also mentioned that the workload on PNF would increase a great deal if the runway is changed, and the ownship is required to start spacing off a new aircraft.

4.7. Recommendations for Further Improvements

Implementing the ATAAS tool with a data link interface for receiving clearance data (lead aircraft identification (ID) and final approach speed, spacing interval) would help simplify necessary interactions with the automation. Modifications could be made to the ND display to simplify training, and would eliminate the minor aspects of the tool that some pilots found confusing.

Addition of wind data to the ADS-B message could improve the accuracy and consistency of the algorithm’s performance in the presence of changing winds. In an actual flight test, the ATAAS performance results could be degraded from those achieved in this study due to the presence of sometimes rapidly changing winds.

Addition of a capability to merge aircraft from different arrival streams into a single stream would expand the usefulness of the ATAAS tool because it is very common in today’s environment for aircraft to arrive from different directions into a common merge point.

5.0. Concluding Remarks

A concept for providing airborne-managed, in-trail spacing in the terminal area was developed and evaluated in a full-workload simulator with airline subject pilots. This concept included procedures for flight crew interaction with air traffic controllers as well as with the onboard algorithm that provides speed commands for achieving a target spacing. Three methods of speed control were evaluated through comparison with a baseline case, in which current-day flight procedures were used.

The main objectives of this study were to evaluate the concept from the standpoint of pilot acceptability, head-down time and workload, and to validate the results seen in a Monte Carlo analysis of the Advanced Terminal Area Approach Spacing (ATAAS) algorithm. The subject pilots generally rated the workload level with the ATAAS procedure as similar to that with standard procedures. They also rated most aspects of the procedure highly in terms of acceptability (though it should be noted that the scenarios reflected a nominal environment, with no winds or abrupt changes in lead aircraft speed).

The subject pilots indicated that the head-down time was slightly higher but acceptable when using the ATAAS tool. Eyetracker data showed no significant change in the amount of time spent looking out the window when ATAAS commands were used.

Data showed the aircraft was able to consistently achieve the target spacing interval when the ATAAS speed command was autothrottle-coupled (Automatic condition). With the speed controlled by the pilot through the Mode Control Panel or manual throttle inputs, the mean spacing interval was slightly greater, but the consistency (standard deviation) was on the same order as in the Automatic condition. This effect is a result of pilot response to the annunciated speed commands and could be mitigated by training or display changes to encourage the pilots to follow the ATAAS speed guidance more closely.

The subject pilots indicated that the simple pilot and controller procedures developed to accompany the tool were highly acceptable. Subject pilots felt that training in a fixed-base simulator is necessary to provide them with the knowledge and capabilities needed to perform this type of procedure.

INSTRUCTIONS TO SUBJECT PILOTS, ATAAS, OCTOBER, 2001

FLIGHT MANUAL BULLETIN

ADVANCED TERMINAL AREA APPROACH SPACING (ATAAS)

BACKGROUND INFORMATION

A method for airborne management of spacing between arriving aircraft in the terminal area has been developed and is being tested in simulation. This method employs an airborne algorithm known as the Advanced Terminal Area Approach Spacing (ATAAS) algorithm, that compares flight profiles of two aircraft and computes a target speed for the following aircraft to maintain. The ATAAS algorithm allows the flight crew to accurately maintain an assigned interval from the aircraft sequenced ahead of it, and has the potential to increase arrival capacity because of increased spacing accuracy. Use of this algorithm requires the flight crew to follow a set of procedures that includes adhering to ATAAS-generated speed guidance cues.

The Air Traffic Service Provider (ATSP) Approach Control will issue a clearance for approach spacing after entry into the terminal area. The crew will be responsible for selecting the assigned traffic to follow from a displayed list, activating the system, and maintaining the commanded speed guidance.

A charted arrival procedure that includes a transition to an ILS approach is used to define the lateral path for the aircraft to maintain. This arrival procedure is defined such that it can also be used by aircraft that are not ATAAS-equipped. Non-equipped aircraft cleared for this arrival must follow the charted speed profile and their spacing will be managed by ATSP.

The ATAAS algorithm is based on a profile similar to the charted speed profile, which emulates the speeds Approach Control normally issues to arriving aircraft. This nominal speed profile may be enabled by engaging the ATAAS system without first selecting a target.

PHRASEOLOGY

Unlike most ATC clearances, the approach spacing clearance requires the use of two call signs, that of the following aircraft and that of the lead aircraft. To reduce the possibility for confusion when an approach spacing clearance is issued, the recommended phraseology should be strictly followed.

Clearance for approach spacing:

ATC: “*(Following AC ID)* spacing interval is ___ seconds behind *(Lead AC call sign)* maintain ATAAS speeds”.

*Appendices A–C are the unedited original versions given to participants.

A/C: “**Approach**, (Following AC ID), spacing interval is ___seconds behind (Lead AC call sign) maintain ATAAS speeds”.

CREW PROCEDURES

There are two separate procedure clearances related to the approach spacing operation. The first is for a Standard Terminal Arrival Route (STAR) charted procedure that transitions onto the ILS approach and is normally issued by the ATSP well before entry into the terminal area. This clearance requires the flight crew to follow a lateral and vertical path, and follow a speed profile. The second clearance is for the approach spacing operation, as discussed in the phraseology section. The flight crew enters the appropriate inputs on the CDU, assesses the commanded speed guidance, advises ATC, and follow the ATAAS speed guidance (assuming the clearance is accepted).

The crew interfaces with the ATAAS algorithm through the Approach Spacing pages on the FMC CDU. These pages are accessed by pressing the ATC function key. There are two pages associated with this operation. The first of these is used to select whether to operate in spacing mode or profile speed mode (see Figure 1). If operating in spacing mode, the lead aircraft identification and time interval to maintain is also entered on this page. The second page is used to enter additional data needed to improve the performance of the ATAAS algorithm (see Figure 2). Data may be entered on this page at any time.

Data to be entered on this page are:

- Own aircraft final approach speed
- Lead aircraft final approach speed
- Minimum distance (if different from minimum wake vortex separation distance)
- Airport surface winds (obtained from ATIS).

The ATAAS speed guidance is coupled to autothrottles with the ATAAS Speed button located on the left side Navigation Display control panel, or can be left in advisory mode and flown with speed controlled either from the Mode Control Panel or manually.

Figure 1. Approach spacing CDU page

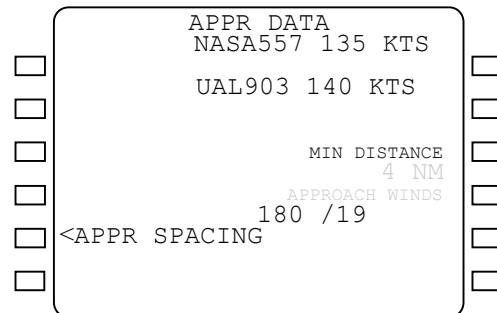

Figure 2. Approach Data CDU page

To operate in profile speed mode, the crew selects the prompt for PROFILE SPEED on the APPROACH SPACING page. Additional data can be entered on the APPROACH DATA page. However, since the aircraft is not maintaining spacing from a lead aircraft, there is no entry for lead aircraft final approach speed or minimum spacing distance.

ATAAS MODE ANNUNCIATION

The ATAAS system is an additional speed mode and will be annunciated on the EADI in the conventional manner:

ATAAS guidance armed “PDA” – mode annunciation in white

ATAAS guidance active “PDA” – mode annunciation in green

Note that if the current aircraft speed is greater than the commanded ATAAS speed, the ATAAS mode will go immediately to “active”.

ALERTS

No EICAS error messages are associated with the ATAAS system

There are no aural alerts associated with the ATAAS system.

If an aircraft is actively spacing behind another aircraft and the ATAAS system determines that the minimum separation standard will be lost, the crew will be alerted on the ND with an amber “Minimum Distance” arc ahead of the aircraft depicting the minimum separation distance and the words “MIN DIST”.

ATAAS APPROACH

NOTE

- ATAAS approaches are not authorized with an engine inoperative or any system irregularity that might compromise the operation
- Maintain speed guidance with autothrottle coupled, with MCP control of autothrottle, or with manual control of throttles
- Expect normal approach clearance

PNF ATIS information.....SS ARR/APPR

C, FO ARRIVAL/APPROACH BRIEF

PNF SPACING CLEARANCE.....SET

- Select traffic to follow
- Enter spacing interval
- Enter own and traffic Final Approach Spds
- Enter minimum distance (if different from standard wake-vortex separation)
- Enter airport winds

PF determines if spacing clearance can be accepted (current interval between -30 sec and +90 sec)

PF, AUTOTHROTTLE (AS DESIRED).....ON

PF ATAAS GUIDANCE.....SELECTED

ND shows traffic ID and spacing interval. EADI shows "PDA", commanded speed

PNF, SPACING CLRNCE....ACKNOWLEDGE

PF, PNF.....MONITOR

If amber MIN DIST arc appears, ensure close adherence to ATAAS speed guidance and notify ATC

This bulletin will be removed when the information is incorporated into the Flight Manual

6. How **confident** were you with the guidance provided by the ATAAS tool during the following phases of the approach procedure:

	Not at all Confident			Borderline			Very Confident
	1	2	3	4	5	6	7
Downwind							
Base							
Final							

7. How **comfortable** were you with using the ATAAS tool during the following phases of the approach procedure:

	Not At All Comfortable			Borderline			Very Comfortable
	1	2	3	4	5	6	7
Downwind							
Base							
Final							

8. Please consider the information sources you used while performing self-spacing related tasks. Estimate the relative amount of time you spent obtaining ATAAS spacing guidance information using each of the four display features listed below. The total should equal 100%.

Feature	% Time
Spacing position indicator with lead aircraft and ownship symbols on ND	
Commanded speed on ND	
Fast/slow indicator with speed bug on EADI	
Commanded speed on EADI	
Total	100%

Appendix B2

Post-Experiment Questionnaire

Advanced Terminal Area Approach Spacing (ATAAS)

January 2002

Katrin Helbing, Paul Mafera, and Rich Adams
Booz Allen Hamilton

For:

Rosa Oseguera-Lohr, Gary Lohr, and Terence Abbott,
NASA Langley Research Center

Acceptability/Feasibility

1. Overall, how comfortable were you in using the ATAAS tool to maintain the assigned spacing in the terminal area?

Completely Uncomfortable			Borderline			Completely Comfortable
1	2	3	4	5	6	7

2. Overall, how effective was the ATAAS tool in helping you maintain the assigned spacing?

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

3. Overall, how does the level of safety provided by the ATAAS tool compare to standard approach procedures?

Compromised			Unchanged			Enhanced
1	2	3	4	5	6	7

4. Overall, how confident were you in the speed guidance provided by the ATAAS tool?

Not at all Confident			Borderline			Very Confident
1	2	3	4	5	6	7

5. How comfortable do you think *other* pilots would be using a tool similar to ATAAS to maintain assigned spacing in the terminal area?

Completely Uncomfortable			Borderline			Completely Comfortable
1	2	3	4	5	6	7

6. How effective do you think a tool such as the ATAAS will be at increasing arrival capacity?

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

7. How well do you think the approach spacing procedures and tools could be integrated into the current flight deck operational environment?

Not At All Effectively			Borderline			Very Effectively
1	2	3	4	5	6	7

13. Compared to standard approach procedures, the amount of time spent looking at displays for the approach spacing procedure was:

Much higher				The same				Much lower
1	2	3		4	5	6		7

14. Can you think of any way of improving the approach spacing clearance procedure?

Flight Management Computer (FMC) Control Display Unit (CDU)

Please answer the following questions as they pertain to your simulator experiences with the CDU ATAAS pages.

15. How confident were you in the process of entering data into the CDU ATAAS pages?

Not At All Confident				Borderline				Completely Confident
1	2	3		4	5	6		7

16. How well do the CDU ATAAS pages provide clear (i.e., unambiguous) and consistent labeling?

Completely Inadequate				Borderline				Completely Adequate
1	2	3		4	5	6		7

17. How well do the CDU ATAAS pages allow for recovery from input errors?

Completely Inadequate				Borderline				Completely Adequate
1	2	3		4	5	6		7

18. The method for selecting the lead aircraft was:

Completely Inadequate				Borderline				Completely Adequate
1	2	3		4	5	6		7

19. The method for entering the spacing interval was:

Completely Inadequate			Borderline			Completely Adequate
1	2	3	4	5	6	7

20. The method for entering additional data (e.g., final approach speed, minimum distance, surface winds) was:

Completely Inadequate			Borderline			Completely Adequate
1	2	3	4	5	6	7

21. How acceptable was the amount of time spent working with the CDU ATAAS pages?

Completely Unacceptable			Borderline			Completely Acceptable
1	2	3	4	5	6	7

22. If you could add one piece of information that is not currently available to the CDU ATAAS pages, what would it be?

23. If you could remove one piece of information from the CDU ATAAS pages, what would it be?

Navigation Display

Please answer the following questions as they pertain to your simulator experiences with the Navigation Display (ND). Refer to the figure provided.

24. How effective was the *spacing position indicator* in communicating whether ownship was 'fast' or 'slow' with regard to the Lead aircraft?

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

25. If the *spacing position indicator* posed a problem, or if some aspect of the indicator stands out as being particularly effective, please comment on how it impacted acceptability, performance, and/or workload.

26. How effective was the *commanded speed* in communicating whether ownship was 'fast' or 'slow' with regard to the Lead aircraft?

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

27. How effective was the highlighting of the *lead aircraft* (i.e., green outline of the aircraft symbol)?

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

28. If you marked 3 or lower on Question 28, please indicate how the highlighting posed a problem or how it may be improved.

29. The method used to indicate a required speed change (flashing box around *commanded speed*) was:

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

30. The amount or density of symbology (too much is called 'clutter') on the ND was:

Completely Unacceptable			Borderline			Completely Acceptable
1	2	3	4	5	6	7

31. If clutter was a problem on the ND, please comment on what was responsible for the clutter.

32a. Did you ever see the minimum distance warning?

No _____ Yes ____ If so:

32b. How effective was the display in communicating a minimum distance warning?

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

33. If you could **add** one piece of information that is not currently available on the ND, what would it be?

34. If you could **remove** one piece of information from the ND, what would it be?

Electronic Attitude Director Indicator

Please answer the following questions as they pertain to your simulator experiences with the Electronic Attitude Director Indicator (EADI). Refer to the figure provided.

35. How effective was the *fast/slow indicator with speed bug* on the EADI in communicating whether ownship was 'fast' or 'slow' with regard to the Lead aircraft?

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

36. How effective was the *commanded speed* on the EADI in communicating whether ownship was 'fast' or 'slow' with regard to the Lead aircraft?

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

37. The amount or density of symbology (too much is called 'clutter') on the EADI was:

Completely Unacceptable			Borderline			Completely Acceptable
1	2	3	4	5	6	7

38. How effective was the method (e.g., color coding, 'speed bug' shape) for indicating the current mode (e.g., armed, engaged) of operation?

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

39. If you could **add** one piece of information to the EADI that is not currently available, what would it be?

40. If you could **remove** one piece of information from the EADI, what would it be?

Training

41. How effective do you feel the training was that you received on the ATAAS tool?

Completely Ineffective			Borderline			Completely Effective
1	2	3	4	5	6	7

42. Do you think ATAAS training could be accomplished with only paper instructions (e.g., user's manual, display diagrams and approach charts, screen shots of sample scenarios, etc.)?

Definitely Not			Maybe			Definitely
1	2	3	4	5	6	7

43. Do you think ATAAS training could be accomplished with only video instructions (e.g., introduction to displays and approach charts, video of sample scenarios, etc.)?

Definitely Not			Maybe			Definitely
1	2	3	4	5	6	7

44. Do you think ATAAS training could be accomplished without practice in a high fidelity aircraft simulator?

Definitely Not			Maybe			Definitely
1	2	3	4	5	6	7

45. If a system similar to the one you just used were to be integrated into your aircraft, what is the minimum training you would need to accomplish the task (think in terms of paper, video and simulator instruction)?

Appendix C

NASA TLX Scale

Mental Demand- How much mental and perceptual activity was required (e.g., thinking, deciding, calculating, remembering, looking, searching, etc.)?

Physical Demand - How much physical activity was required (e.g., pushing, pulling, turning, controlling, activating, etc.)?

Temporal Demand - How much time pressure did you feel due to the rate or pace at which the tasks or task elements occurred?

Performance - How successful do you think you were in accomplishing the goals of the task set by the experimenter (or yourself)? How satisfied were you with your performance in accomplishing these goals?

Effort - How hard did you have to work (mentally and physically) to accomplish your level of performance?

Frustration - How insecure, discouraged, irritated, stressed and annoyed versus secure, gratified, content, relaxed and complacent did you feel during the task?

MENTAL DEMAND

PHYSICAL DEMAND

TEMPORAL DEMAND

EFFORT

PERFORMANCE

<p>The public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Department of Defense, Washington Headquarters Services, Directorate for Information Operations and Reports (0704-0188), 1215 Jefferson Davis Highway, Suite 1204, Arlington, VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to any penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.</p> <p>PLEASE DO NOT RETURN YOUR FORM TO THE ABOVE ADDRESS.</p>

14. ABSTRACT The Advanced Terminal Area Approach Spacing (ATAAS) tool uses Automatic Dependent Surveillance-Broadcast aircraft state data to compute a speed command for an ATAAS-equipped aircraft to follow and obtain a required time interval behind another aircraft. The ATAAS tool and candidate operational procedures were tested in a high-fidelity, full mission simulator with active airline subject pilots flying an arrival scenario to obtain pilot perceptions of acceptability and workload for the concept. The aircraft consistently achieved the target spacing interval within 1 s when the ATAAS speed guidance was autothrottle-coupled and a slightly greater (4–5 s) but consistent interval with pilot-controlled speed changes. The subject pilots rated the ATAAS workload as similar to one with standard procedures for a nominal Instrument Landing System (ILS) approach. They also rated highly various procedural aspects (including amount of head-down time required). Eyetracker data showed only slight changes in instrument scan patterns for ATAAS versus standard ILS procedures.					
15. SUBJECT TERMS Approach spacing; Air traffic control; ADS-B; Flight deck tool
