FINAL REPORT
Contract NAS5-32483

Augmentation of the IUE Ultraviolet Spectral Atlas
Principal Investigator: Chi-Chao Wu

Under this program, the Principal Investigator (PI) continued observations of normal stars in order to fulfill the following two goals: (1) to provide a stellar library as complete as practical, which will be able to support astronomical research by the scientific community long into the future, and (2) to obtain a sufficient sample of stars to guard against variability and peculiarity, and to allow a finite range of temperature, gravity, and metallicity in a given spectral type-luminosity class combination.

The candidate stars have been selected such that they are not spectroscopic binaries or variables with significant changes in magnitude or color, they have well determined spectral types, and if possible, they have small interstellar reddening. Most of the observations were made with the trail and pseudo-trail techniques, and at optimum exposure, in order to achieve maximum signal-to-noise ratio for the spectra.

The PI and his collaborators have completed the reduction of the data obtained during the IUE twelfth through seventeenth episodes: SALCW, SAMCW, SANCW, SAOCW, SAPCW, and SAQCW. The data are presented in The *IUE Ultraviolet Spectral Atlas, Addendum II*, by C.-C. Wu, F. H. Schiffer, 3rd, and D. M. Crenshaw (see attachment).

This second addendum of the spectral atlas contains 183 stars. Combining with the 315 stars presented in the original spectral atlas (Wu *et al* 1983, *NASA IUE Newsletter* 22), and its first addendum (Wu *et al* 1991, *NASA IUE Newsletter* 43), the stellar library contains 498 stars. It covers spectral types from O3 to M7, with good representation for the main sequence, and reasonably good sample for higher luminosity stars. We believe this porject has fulfilled the two goals mentioned in the first paragraph.

The second addendum contains spectral plots and flux tables (samples are given in the attachment for three stars). Stars earlier that F3 have data from 1150 to 3200 angstroms (have both the SWP and LWP images), and stars later than F6 have data from 1974 to 3200 angstroms (LWP only). The production of Addendum II is essentially complete. Minor cosmetic changes are being made to the plots and tables for a few stars. The paper version will be submitted to the *NASA IUE Newsletter* for publicaiton. The electronic copy will be made available to the IUEDAC and NSSDC.

THE IUE ULTRAVIOLET SPECTRAL ATLAS ADDENDUM II

Chi-Chao Wu , Francis H. Schiffer, 3rd, D. Michael Crenshaw
Science Programs, Computer Sciences Corporation

I. Introduction

The IUE Ultraviolet Spectral Atlas and the first addendum were published by Wu et al. (1983, 1991) in printed and machine readable versions. This atlas and addendum contain UV spectra of 315 stars with spectral types ranging from O3 to M5 and many spectral type-luminosity class combinations. There were three criteria for selecting these stars: (1) they were not spectroscopic binaries or variables with significant changes in magnitude or color, (2) they must have well-determined spectral types (many are MK standards) and (3) the stars should not be heavily reddened.

Further augmentation of the atlas is desirable to provide a more complete coverage of the spectral type-luminosity class combinations and more than one star per combination. The extra spectral type-luminosity class combinations reduce the need for interpolation. The extra stars within a given combination guard against variability and peculiarity, and allow for a finite range of temperature, metallicity and gravity.

The previous atlas and addendum presented data that were obtained through the eleventh episode under IUE programs with C.-C. Wu and D. Burstein as principal investigators. In this second addendum, we present the spectra obtained by Wu's programs during the twelfth through seventeenth episodes: SALCW, SAMCW, SANCW, SAOCW, SAPCW and SAQCW. During the period between July 1989 and September 1994, Wu observed 183 stars under these programs. Most of these observations are high quality trails or pseudo-trails (multiple exposures in the large aperture).

II. Observations and Reductions

The observations for this atlas were made with the IUE using the Short Wavelength Prime (SWP) and Long Wavelength Prime (LWP) cameras in low dispersion mode. The SWP camera covered the 1150-1974 Å region. The LWP camera covered the 1974-3200 Å region. The IUE cameras have a spectral resolution of about 6 Å in low-dispersion mode. Boggess et al. (1978a, b) presented the first discussion of the IUE scientific instrument and its performance. For more recent updates, readers should consult Sonneborn et al. (1987), Harris and Sonneborn (1987), and Grady and Taylor (1989).

Most of the observations used the trail or pseudo-trail technique to increase the signal-to-noise ratio. These techniques increased the exposure time by moving the target star along the major axis of the large aperture, which is nearly perpendicular to the dispersion direction. In a trailed exposure, the star moves at a constant rate through the large aperture. Generally, we used this method when the total exposure time was less than 10 minutes and the star was within 100

degrees of the Sun. When a star was more than 100 degrees from the Sun or the exposure time for trailing was more than 10 minutes, the pseudo-trail technique provided the increased exposure time. This pseudo-trail technique places the star at several discrete locations (generally 3) along the major axis. The camera takes an exposure at each location without reading out the data while a guide star stabilizes the spacecraft. The widened spectra obtained by these techniques improved the signal-to-noise ratio by collecting more photons and by recording the spectra on more image pixels. The use of more image pixels improved the chance of averaging out the fixed-pattern noise. Spectra through the small aperture provided data in wavelength regions, which contained saturation, low exposure levels, reseaux or other blemishes in the large aperture spectra.

The input for this atlas was the merged spectra, which the IUESIPS production software created on the date of the processing. Turnrose and Thompson (1984), Harris and Sonneborn (1987), and Grady and Taylor (1989) provide detailed discussions of this IUE image processing system. Bohlin and Holm (1980) provided the absolute calibration for the SWP spectra. This calibration was described in more detail by Holm et al. (1982). Cassatella, Lloyd, and Gonzalez Riestra (1987) were the source of the calibration for the LWP data.

The IUE Data Analysis Center (IUE DAC) in the Laboratory for Astronomy and Solar Physics at Goddard Space Flight Center (GSFC) provided the facilities and software for further custom reductions. These reductions included corrections to all fluxes for exposure time and temperature effects. The fluxes of the small aperture spectra are not on an absolute scale due to the uncertainty in the small aperture throughput. The ratio of the large to small aperture fluxes for the same star provided a correction for this uncertainty. This ratio used only the fluxes in regions unaffected by bad data and with measurable signal. The correction placed the fluxes and exposure time of the small aperture spectrum on the same absolute scale as the large aperture spectrum. Multiple spectra of the same star and in the same wavelength range were combined into an averaged spectrum. The combination weighted each spectrum by its exposure time. These averaged spectra excluded any data that contained saturation, reseaux, flagged bright spots or microphonic noise. The final step in the custom reductions was to bin the spectra at 2 Å intervals.

This addendum contains spectra for 183 stars and spectral types from O7 to M6. Stars earlier than F3 have both SWP and LWP data. For stars later than F6, only LWP spectra are presented. Table I catalogues the stars in order of spectral type-luminosity class. Columns (1) and (2) give the HD number and name of the star, respectively. Column (3) gives the spectral type as published in the reference, a code for which appears in Column (4). An explanation of these codes appears at the end of Table I. Columns (5) and (6) contain the right ascension and declination (1950 epoch) for the star. Columns (7) and (9) give V and B-V respectively. The primary source of these photometric data was Mermilliod and Mermilliod (1994). For HD 216399, O'Connell (1973) provided the V magnitude and SIMBAD the B-V. The photometry for HD 219188 came from Turon et al. (1992). In Column (8), an "A" shows that the star has a close neighbor and that the V

magnitude is only for the brighter component. On the other hand, an "AB" in Column (8) indicates that the V magnitude is the combined brightness of both components. The entries in Column (8) are from Mermilliod and Mermilliod (1994). The E(B-V) value, which appears in Column (10), is the observed B-V from Column (9) minus the intrinsic B-V from FitzGerald (1970). The E(B-V) values assume that the intrinsic B-V's for higher luminosity O stars are the same as main sequence stars of the same spectral type. The computations of E(B-V) for spectral types and luminosity classes, which have no intrinsic B-V in FitzGerald, used interpolated values of B-V.

Table I contains information about the IUE images for each star as well. The IUE image number appears in Column (11). Column (12) contains a flag for the aperture, where "L" is the large aperture and "S" is the small aperture. Column (13) defines the observing technique. A "T" in Column (13) means trailed. A number represents the number of exposures in the single image. A value greater than one (like 3 or 4) in the large aperture implies that the image used the pseudo-trail technique. The total exposure time in seconds appears in Column (14). A correction to the exposure time was necessary for the single and multiple (pseudo-trail) exposure spectra, if the time for the individual exposure was 60 seconds or less. The correction accounted for two factors, which can cause errors in the exposure time of 0.5 percent or higher (Schiffer 1980; Crenshaw 1986). First, the IUE on-board computer controls the exposure time in discrete steps of 0.4096 seconds each. Second, the camera takes 0.120±0.015 seconds to turn on at the start of an exposure. Therefore, the actual exposure time is

$$\text{Actual Exposure Time} = [\text{Integer}(t_c/0.4096) \times 0.4096] - 0.120,$$

where t_c is the commanded exposure time in seconds from the IUE observing script. Column (14) contains the exposure time, which is the sum of the actual exposure times from the above equation. For trailed spectra, the exposure time is equal to the trail length in arcseconds divided by the trail rate in arcseconds per second. The actual trail length is 21.4 and 20.5 arc seconds for the short and long wavelength spectrographs, respectively (Panek 1982). The observing script records the trail rate. The result from the exposure time computation, which used the actual trail length, the trail rate and the number of passes, appears in Column (14). The exposure time that is on the observing script and in the IUE image header assumes a trail length of 20 arcseconds and so is not accurate. Column (15) records the temperature of the camera head amplifier during the exposure. This temperature determined a small correction of camera sensitivity (Garhart and Teays 1989).

An indicator of the exposure level appears in Column (16). The values are either a data number (DN) or an overexposure level. The DN values range from 0 to 255. At a DN of 255, the spectrum contains at least one overexposed pixel. The estimated level of overexposure appears as a number followed by "x". For example, 3x means approximately three times overexposed. Three exposure level values are given in Column (16): "E" is for the strongest emission line, "C" is for the continuum, and "B" is for the background regions, which are immediately adjacent to the

spectrum. The Telescope Operator measured these levels during the quick-look analysis of the images and recorded them on the observing script. They serve as a rough indicator of the quality and utility of the data. The emission line indicators do contain errors. For instance, the emission level may be missing for a weak emission component of a P-Cygni profile or Mg II line at 2800 Å. Another common error was to misidentify a less absorbed region in the heavily absorbed spectrum of a late type star as an emission line.

In this addendum, there is a plot for each averaged spectrum. The scales of these plots are the same as in the earlier installments (Wu et al. 1983, 1991). On the page facing each plot, there is a table of average fluxes in 2 Å wavelength bins. In the spectral plots, the regions with bad data (nearly saturated data, reseaux or blemishes) are blank. The values in the flux tables also omit these bad data. The omission of the nearly saturated data is a change from the earlier atlas and addendum. This change is due to the realization that the responses of the cameras are very nonlinear for data values near saturation. In spectral regions where the signal-to-noise ratio is low (e.g., the short wavelength end of the LWP spectra), negative fluxes can appear in the tables.

The merged files for the individual spectra in this addendum have been sent to the IUE DAC and the National Space Science Data Center (NSSDC) at GSFC. If you have an interest in receiving a copy of the data, requests should be sent to the IUE Observatory or the NSSDC.

We thank Dr. Conrad Sturch for his helpful discussions on the stellar photometry. This work was supported by the NASA IUE research contracts NAS5-28749, NAS5-31846, NAS5-32478 and NAS5-32483 to the Computer Sciences Corporation.
