## Preface

---

This technical report is an update to *LPI Technical Report 89-02* (*Schutt et al.*, 1989), which contained data and information that was current to May 1987. Since that time approximately 4000 new meteorites have been collected, mapped, and characterized, mainly from the numerous icefields in the Allan Hills–David Glacier region, from the Pecora Escarpment and Moulton Escarpment in the Thiel Mountains–Patuxent region, the Wisconsin Range region, and from the Beardmore region. Meteorite location maps for icefields from these regions have been produced and are available. This report includes explanatory texts for the maps of new areas and provides information on updates of maps of the areas covered in *LPI Technical Report 89-02*. Sketch maps and description of locales that have been searched and have yielded single or few meteorites are also included. The meteorite listings for all the icefields have been updated to include any classification changes and new meteorites recovered from icefields in the Allan Hills–David Glacier region since 1987. The text has been reorganized and minor errors in the original report have been corrected.

Computing capabilities have improved immensely since the early days of this project. Current software and hardware allow easy access to data over computer networks. With various commercial software packages, the data can be used many different ways, including database creation, statistics, and mapping. The databases, explanatory texts, and the plotter files used to produce the meteorite location maps are available through a computer network. Information on how to access AMLAMP data, its formats, and ways it can be used are given in the User's Guide to AMLAMP Data section. Meteorite location maps and thematic maps may be ordered from the Lunar and Planetary Institute. Ordering information is given in Appendix A.

 Appendix A. Antarctic Meteorite Location and Thematic Map Order Form	

# Introduction

---

Antarctica has been a prolific source of meteorites since meteorite concentrations on bare ice stranding sites were discovered in 1969 (*Yoshida et al.*, 1971). Since 1976 the U.S. has joined Japan and a consortium of European countries (EUROMET) as nations that have sent expeditions specifically to search for meteorites in Antarctica. About 14,000 meteorite specimens have been recovered as a result of these efforts. The U.S. program, currently under the direction of W. A. Cassidy and J. Schutt of the University of Pittsburgh and R. Harvey of the University of Tennessee, is supported by the Office of Polar Programs of the U.S. National Science Foundation. The Antarctic Search for Meteorites (ANSMET) project has been active over much of the Trans-Antarctic Mountain Range. The first ANSMET expedition (a joint U.S.-Japanese effort) discovered what turned out to be a significant concentration of meteorites at the Allan Hills in southern Victoria Land (*Cassidy*, 1977, 1978, 1979). Later reconnaissance in this region resulted in the discovery of meteorite concentrations on icefields to the west of the Allan Hills, at Reckling Moraine, and Elephant Moraine (*Cassidy*, 1980; *Cassidy and Annexstad*, 1981; *Schutt*, 1982; *Cassidy et al.*, 1983; *Cassidy and Schutt*, 1984; *Huss et al.*, 1987).

ANSMET expeditions have also found important concentrations in other regions of Antarctica; the Lewis Cliff-Walcott Névé area in the Beardmore region has proved to be as important as the Allan Hills icefields in numbers of specimens recovered (*Cassidy et al.*, 1986, 1987) and the Thiel Mountains-Pecora Escarpment region has also produced significant numbers of meteorites (*Schutt et al.*, 1983; *Harvey and Schutt*, 1992). Numerous other less productive areas have been identified, as well as a small number of individual meteorite finds (*Cassidy*, 1977, 1979; *Cassidy and Annexstad*, 1981; *Schutt et al.*, 1983; *Cassidy et al.*, 1986; *Harvey and Schutt*, 1992). Additional new and important meteorite stranding sites and individual finds will undoubtedly be found in the future. Figure 1 shows the general location of meteorite concentrations and individual finds in Antarctica. Table 1 is a listing of these areas, the name abbreviations used for identifying meteorites found there, and the locale's geographic coordinates. A summary of Antarctic meteorite field work, overviews of meteoritic and related glaciological investigations, and discussions on concentration mechanisms can be found in *Bull and Lipschutz* (1982), *Annexstad et al.* (1986), *Cassidy and Whillans* (1990), *Huss* (1990), and *Cassidy et al.* (1992).

The mapping of the locations of meteorites found on the Antarctic icesheet can play an important role in meteorite and glaciological investigations. Maps are visual aids in pairing studies, especially when fragments of the same fall are found in a given area during different field seasons. The

spatial distribution of meteorites on a given stranding surface may give insights into the concentration mechanism(s) or define areas in which glaciological studies should be concentrated. Thematic maps and spatial analysis of meteorite types, masses, terrestrial ages, or combinations of those parameters will yield additional clues.

We are preparing Antarctic meteorite location maps for the specimens found by the ANSMET project and others. We have prepared this report to accompany the meteorite location maps that have been produced to date. The report is at once a catalog of meteorite find sites in Antarctica and a brief history of search and recovery efforts. For areas where meteorites have been found in great numbers, large (33" x 44", E-size) maps have been created and are available from the LPI (see Appendix A). Reduced versions of these maps are shown in the following sections. For areas where few or single specimens were found or in areas where meteorites were found outside the bounds of these maps, we have used references in the explanatory texts, air-photos, satellite images, sketch maps, and published U.S.G.S. maps to document the meteorite locations.

The meteorite location maps have been organized into map series and subseries based upon a broad, regional scale and local subseries within regions. For example, the Allan Hills-David Glacier Region Meteorite Location Map Series currently includes the Allan Hills Map Series (ALHA and ALH meteorites) and the Elephant Moraine Map Series (EETA and EET meteorites).

## HISTORY OF METEORITE LOCATION MAPS AND FIELD MAPPING PROCEDURES

*Yanai* (1983, 1984) published meteorite location sketch maps for the Yamato Mountains and the Allan Hills. The Allan Hills map shows the locations of specimens recovered during the 1976-1977, 1977-1978, and 1978-1979 seasons. The Antarctic Meteorite Location and Mapping Project (AMLAMP) grew out of a need to present the location data that had been acquired in subsequent years by the ANSMET expeditions.

The first maps of the Allan Hills Main and Near Western icefields and the Elephant Moraine Icefield were hand-drawn versions. T. Meunier (U.S. Geological Survey) produced a computer-generated map showing meteorites recovered during the 1982-1983 search of the Far Western Icefield. A copy of the Cartographic Automatic Mapping (CAM) program that he used was acquired from the U.S.G.S. and installed, after modification, into the DEC-VAX computer system at the LPI.

The CAM program is a powerful cartographic mapping software package, capable of generating maps in many map

projections. By present standards, however, it is a cumbersome and inelegant program with numerous limitations. Many corrections and enhancements have been made to the CAM program. Because meteorite locations are often close together, a utility program was written so that name placement overprinting is minimized. An interactive editing program is used to finalize name positioning. Numerous other programs have been developed to deal with the different kinds of data and data formats. We have essentially created a crude geographic information system (GIS). Thematic maps may be created within our framework of programs. However, the location data is in geographic coordinates and therefore can easily be imported into a dedicated GIS environment.

Separate databases have been created for each of the icefields from reduced field and survey data and from computer databases at the Antarctic Meteorite Laboratory at the Curatorial Facility, Johnson Space Center (JSC). To date, these databases include specimen names, classifications, masses, locations, and map data. Terrestrial ages of the meteorites will be added when enough have been determined. The AMLAMP databases are updated once a year to include any new information.

A variety of field methods has been used to document and determine the locations of meteorites. Crude surveying methods (with an estimated precision of 10 m) were used from the 1978–1979 season until late in the 1983–1984 season, when a theodolite and electronic distance measuring (EDM) instrument became available. During the 1982–1983 season a TRANSIT satellite surveying instrument was used to make precise position determinations of three base stations at the Allan Hills Far Western Icefield (Cassidy *et al.*, 1983). In the following season, an open-survey traverse was made from these points, crossing the Middle Western and Near Western icefields, and ultimately tying into the network established at the Main Icefield by Nishio and Annexstad (1979). Although subject to the accumulation of a large error, this traverse tied the icefields together and provided base stations to which individual meteorite locations could be tied.

Two base stations at the Lewis Cliff were initially placed by surveyors from the U.S.G.S. during the 1985–1986 season. The geographic position of one of these was determined by resection methods and is the basis for the network of base stations used for surveying in the Lewis Cliff area. At the Texas Bowl Icefield, during the 1990–1991 field season, a TRANSIT satellite surveying instrument was again used to determine, by translocation, the geographic coordinates of two points used as base stations for the local survey network.

During the 1990–1991 season, Global Positioning System (GPS) receivers were acquired. GPS has become the standard means of determining most base station positions and meteorite positions. All the meteorites from the Queen Alexandra Range–Goodwin Nunataks area, the Wisconsin

Range–Upper Reedy Glacier area, the Patuxent Range–Brazitis Nunatak Icefield, and the Thiel Mountains–Moulton Escarpment Icefield were determined by averaged point positioning of GPS determinations. Tests indicate that the accuracy of this method is highly variable, but at worst is around  $\pm 30\text{--}40$  m. In other areas, a differential method of postprocessing GPS data is used to achieve higher positional accuracy of  $\pm 2\text{--}8$  m. The theodolite/EDM is still used to survey meteorites found in high densities.

## AMLAMP METEORITE LOCATION MAPS

Except in a couple of instances, we have been developing large-scale meteorite location maps of meteorite stranding sites for which the detailed, systematic searches by ANSMET field parties is essentially complete. For other sites, meteorite location data exist and maps are in various stages of development, but formal maps and databases have not been produced. Eighteen map sheets for 13 major meteorite stranding surfaces are currently available, with the Allan Hills–David Glacier Region Map Series and the Beardmore Region Map Series most fully developed.

Maps are plotted either in the Universal Transverse Mercator (UTM) Projection or the Polar Stereographic Projection. These are conformal, plane-rectangular coordinate systems. A grid system is placed on the maps as a visual aid in gauging distances and locating specific meteorites. The grid crosses are based on the UTM coordinate system or on geographic latitude and longitude intersections, depending upon the map projection used, and are at various spacings, due to differences in map scales. For maps plotted in the UTM projection, the UTM coordinate values are included on the map for reference. The crosses define grid cells that can be used in locating specific meteorites using an alphanumeric “street map” system. For example, to locate ALH 84113, find its grid cell in the meteorite listing in the Near Western Icefield chapter. F-8 is the coordinate pair of that grid cell. On the map the numbers are found along the north and south margins and the letters along the east and west sides.

Map scales vary as a function of the long dimensions of the icefields, the densities of data points that must be presented, and limitations of the CAM program and plotting facilities. Where very high densities of meteorites were found, insets of the area at a larger map scale have been added. Geographic latitude and longitude tick marks are located along the map borders. North is always toward the top. Geographical features such as bedrock, moraine, and icefield boundaries have been derived from field data, aerial photos, and satellite images. These were added by hand to draft versions of the maps using projection or zoom transfer scope methods. The feature lines were then digitized. These boundaries should be considered as generalized features in most cases, though meteorite

location and survey data provide some control.

Pairing of meteorites found within a given field season has long been a problem. In many instances a meteorite has been found as fragments obviously scattered downwind over the ice. In some cases, upward of 100 fragments are recovered in such a situation. These have been collected using one field number and therefore are given a single name. The collection teams have documented the limits of these scatter fields and their outlines are plotted on the maps. In many cases meteorites have been collected and mapped as individual specimens, but have been paired later and given a single official name upon processing at JSC, based upon field notes and common features (i.e., fragments that fit together, composition, type, etc.). In some cases, members of pairing groups were found great distances apart. This can pose problems in a spatial database where unique identifiers of points are required. We have chosen to use the meteorite name followed by its fragment number as a means of identifying paired specimens. For example, EET 90053,0 and EET 90053,17 are paired fragments, yet were found almost 2.5 km apart on the Texas Bowl Icefield. Other paired specimens have been found up to 35 km apart.

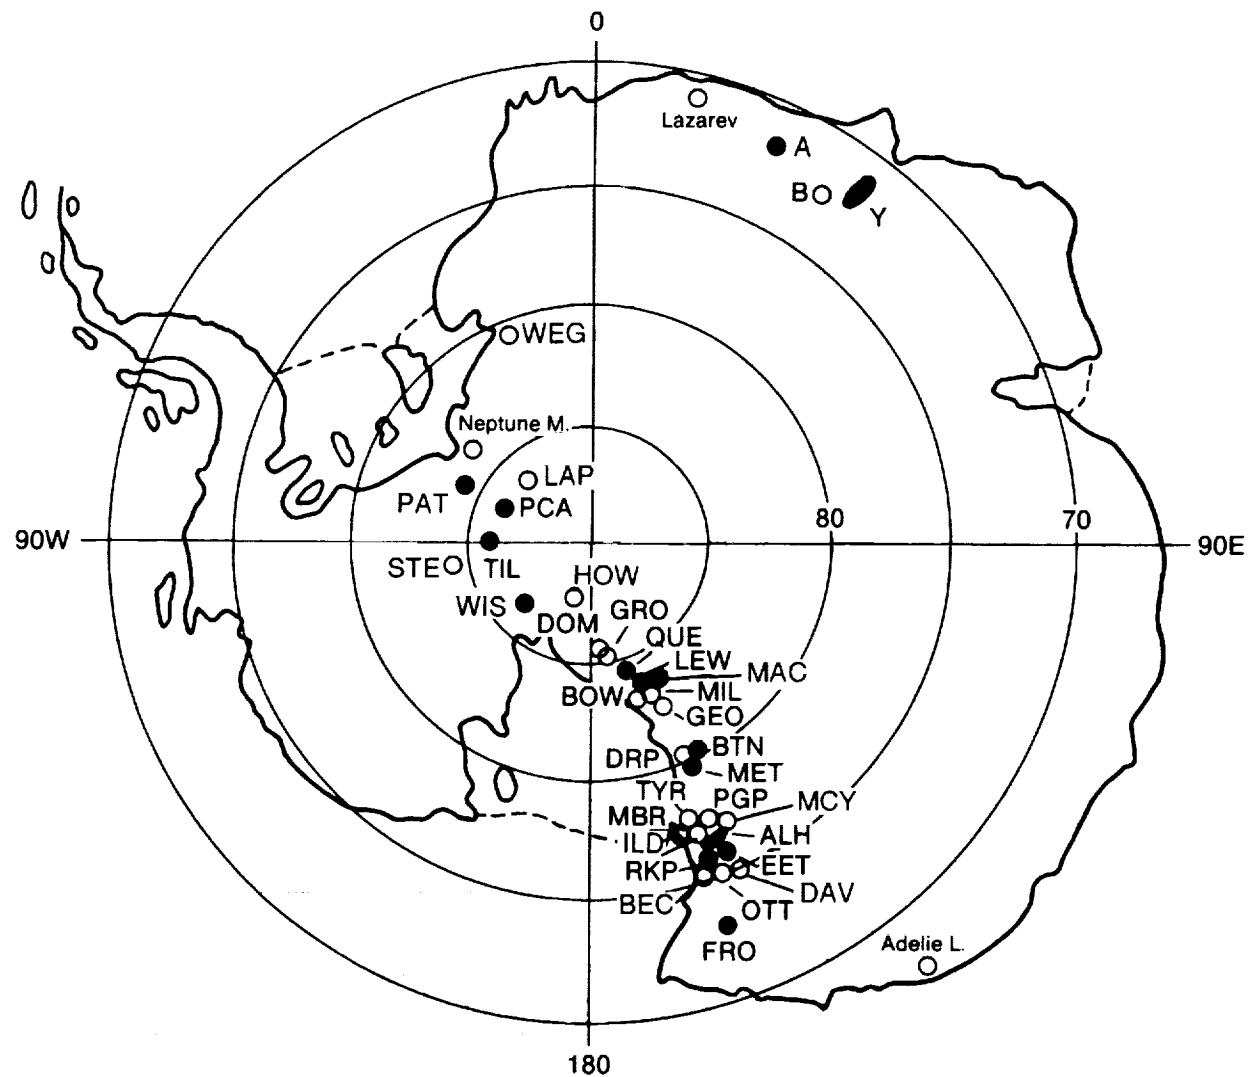

### EXPLANATORY TEXTS

Explanatory texts for the meteorite location maps are found in the following sections. Detailed background, meteorite, and map information are given for each icefield. Included are listings of all meteorites recovered from the given icefield, except for the Allan Hills Main Icefield 1976–1977, 1977–1978, and 1978–1979 collections, which have been documented by Yanai (1983). The listings of meteorites recovered from the different areas contain information current with the date of this publication. Meteorite name, classification, weight, and grid cell coordinate are provided. Also included in the listings is the *Antarctic Meteorite Newsletter* reference [Vol. (No.)] for each meteorite. In some cases there are multiple newsletter references because of classification changes; these listings give only the issue in which the meteorite was first described. Collections for some of the map areas are yet to be completely classified, so this information could not be included. Also included are tables that list the types of meteorites

recovered and their numbers from a particular icefield. Further information on specific meteorites can be obtained from the *Lunar and Planetary Bibliography* maintained on the VAX computer at the LPI as well as the *Antarctic Meteorite Newsletter*.

Icefields with meteorite concentrations are always associated with single or multiple escarpments or steplike topographic features. The upper break in slope generally parallels the long dimension of an icefield, and usually strikes perpendicular to the direction of ice sheet flow. Slope profiles are given in the explanatory texts for some of the mapped icefields. These profiles are based on widely spaced survey data and field observations, and are therefore only diagrammatic. The profiles were selected in areas where a reasonable amount of survey data were present and they may not be entirely representative of other sections on that particular icefield. The downslope katabatic wind flow, which is responsible for exposing the ice, preventing snow accumulation, contributing to the ablative effects, and the concentration of small meteorite specimens at the downwind ice edge, is generally normal to the escarpments. More complete descriptions of the field settings of meteorite concentrations can be found in Annexstad *et al.* (1986), Bull and Lipschutz (1982), Cassidy and Whillans (1990), and Cassidy *et al.* (1992).

**Acknowledgments:** The surveying and mapping of the meteorite locations and icefields could not have been accomplished without the assistance and perseverance of ANSMET expedition members, often under adverse conditions. R. Score provided considerable assistance with the JSC meteorite databases. R. Walker provided some of the enlargements of the satellite images used in the explanatory texts and support for AMLAMP and the initial acquisition of GPS equipment. K. Burke, D. Black, K. Leung, and others on the staff of the LPI gave cheerful support and advice to the project. A. Kubala assisted in the production of map and database updates. The LPI Publications and Program Services Department staff contributed significantly to the report. The Meteorite Working Group was also forthcoming with encouragement and support. M. Zolensky offered helpful suggestions and comments on the text. ANSMET field work was conducted under National Science Foundation Grants DPP 77-21742, 78-21104, 83-14496, 88-17083, and 91-17558.

**Fig. 1.** Find localities of Antarctic meteorites. Filled symbols indicate stranding sites with many specimens.

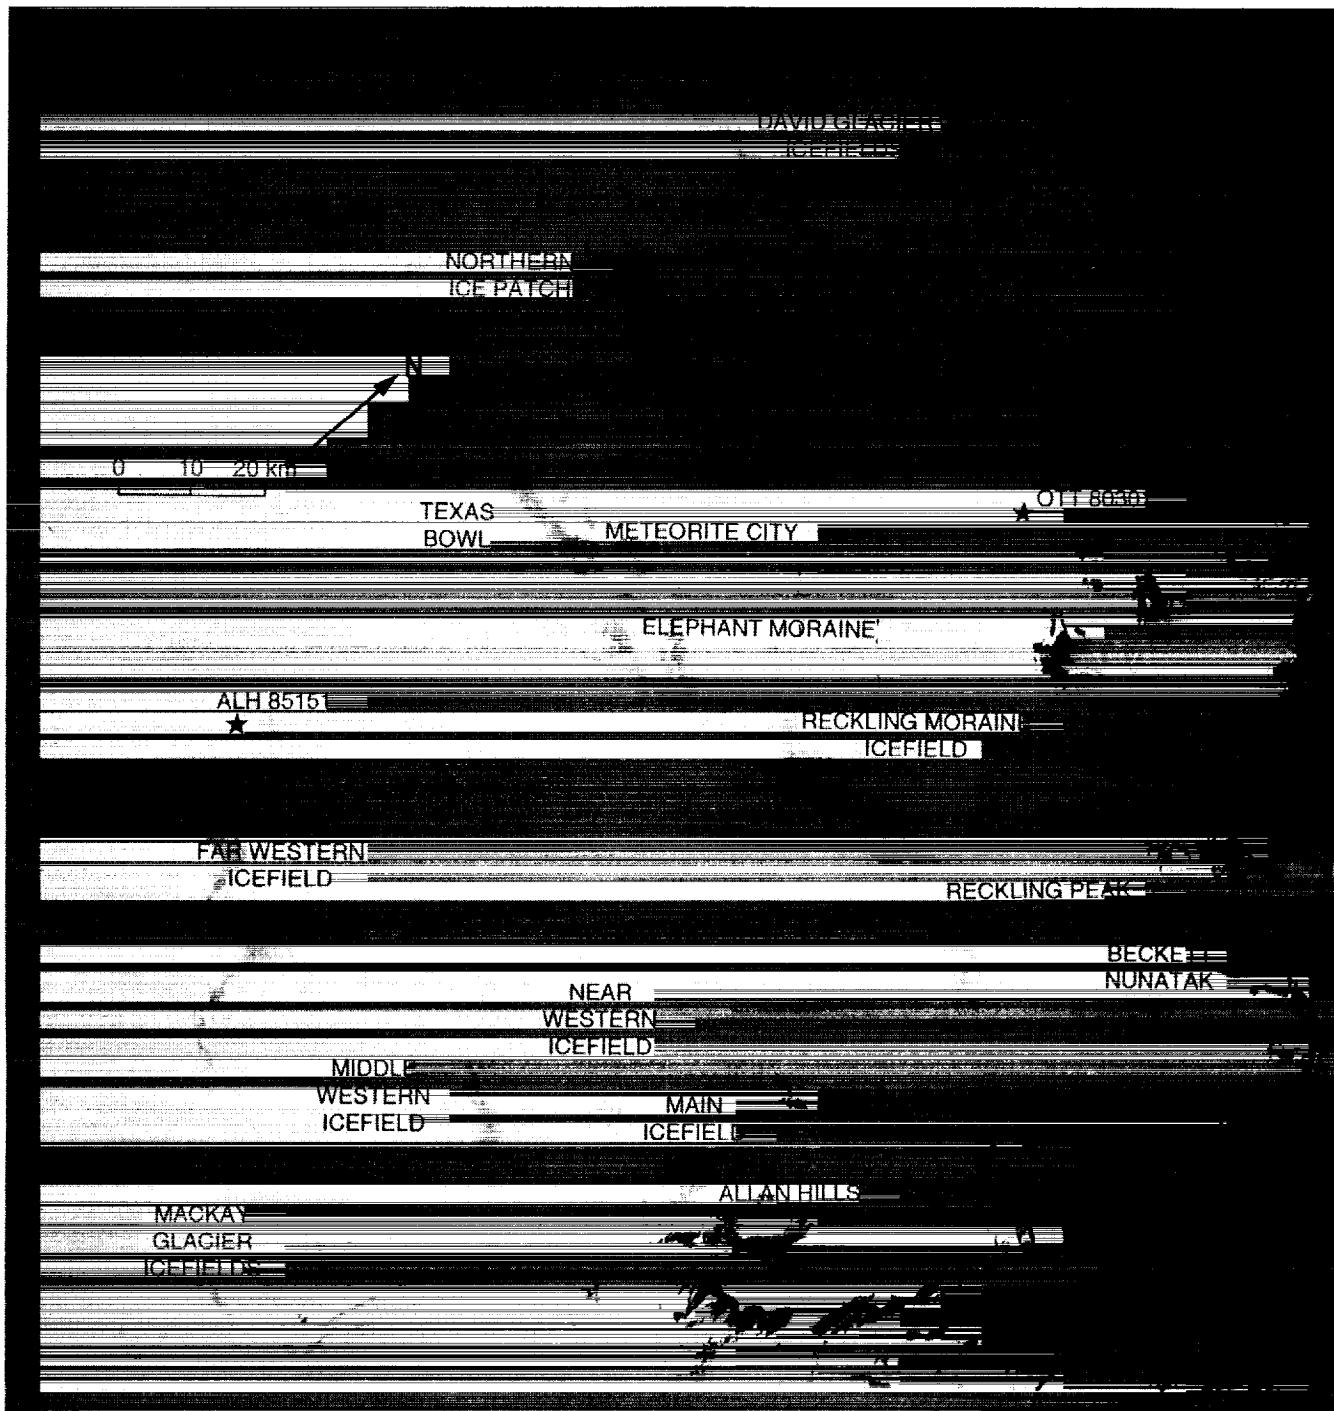

TABLE I. Meteorite name abbreviation and coordinates\* of Antarctic meteorite find localities  
(after Annexstad *et al.*, 1986).

\*The geographic coordinates of the features after which the meteorites are named are derived from *Alberts* (1981) and are not necessarily a representative location coordinate for the meteorite stranding surface or their find sites.

<sup>†</sup>The LaPaz Icefield is a previously unknown geographic feature some distance from any officially named feature. The name is informally used at this time.

<sup>‡</sup>The earlier individual meteorite finds named Adelie Land (1912), Lazarev (1961), Neptune Mountains (1964), and Thiel Mountains (1961) do not have name prefixes. TIL represents the current name prefix for later finds in the Thiel Mountains region.

**Fig. 2.** Satellite image of the Allan Hills David Glacier region, Victoria Land. (Enhanced image courtesy of the U.S.G.S.)

## ALLAN HILLS-DAVID GLACIER REGION METEORITE LOCATION MAP SERIES

The Allan Hills-David Glacier region (covered by the 1:250,000-scale U.S. Geological Survey Convoy Range and Mt. Joyce maps) of Victoria Land has been an important source of meteorite specimens since the initial discovery of meteorites at the Allan Hills in the austral summer of 1976–1977. Approximately 3300 meteorite specimens have been recovered from icefields in the region. Figure 2 shows the major icefields and features in the region. Most of the collection work in the early years of the Antarctic Search for Meteorites project (ANSMET) concentrated on systematic searches of the icefield in the immediate vicinity of the Allan Hills (the Main Icefield), but reconnaissance and subsequent systematic searches of ice patches lying some distance to the west and southwest indicated meteorites in significant numbers. These are geographically distinct from the Main Icefield and are now called the Allan Hills Near Western Icefield, the Allan Hills Middle Western Icefield, and the Allan Hills Far Western Icefield. Reconnaissance of the Reckling Moraine Icefield and Elephant Moraine Icefield in 1978–1979 and 1979–1980, respectively, showed there was good potential for meteorite concentrations at those sites. Subsequent systematic searches there resulted in the recovery of significant numbers of meteorites. In 1982–1983 and 1987–1988, reconnaissance of icefields to the west and north of Elephant Moraine resulted in the discovery of local areas with abundant meteorites, now informally referred to as Texas Bowl, Meteorite City, and the Northern Ice Patch.

The following maps (with the latest edition) of the Allan Hills-David Glacier Region Meteorite Location Map Series have been developed and are currently available.

*Allan Hills Main Icefield Meteorite Location Map, North Section (1993 edition)*

- Allan Hills Main Icefield Meteorite Location Map, South Section (1993 edition)*
- Allan Hills Near Western Icefield Meteorite Location Map (1987 edition)*
- Allan Hills Middle Western Icefield Meteorite Location Map (1987 edition)*
- Allan Hills Far Western Icefield Meteorite Location Map, West Section (1987 edition)*
- Allan Hills Far Western Icefield Meteorite Location Map, East Section (1991 edition)*
- Elephant Moraine-Elephant Moraine Icefield Meteorite Location Map (1991 edition)*
- Elephant Moraine-Texas Bowl Icefield Meteorite Location Map (1993 edition)*
- Elephant Moraine-Northern Ice Patch Meteorite Location Map (1993 edition)*
- Reckling Peak-Reckling Moraine Icefield (1993 edition)*

There have been finds of single or limited numbers of meteorites from other locations in the region. One specimen (OTT 80301) was found mixed in with abundant terrestrial material on ice near Outpost Nunatak. Another specimen (ALH 85151) was recovered from a small, isolated icefield 15 km north of the Allan Hills Far Western Icefield. These locations are indicated in Fig. 2. During reconnaissance in 1992–1993 two specimens were found on small ice patches north of Beckett Nunatak. North of the Elephant Moraine Northern Ice Patch, at the head of the David Glacier, eight specimens were recovered from some of the David Glacier icefields. Four meteorites were discovered on small, isolated ice areas at the head of the Mackay Glacier, southeast of the Far Western Icefield, again during reconnaissance in 1992–1993.

**Fig. 3.** Enlarged portion of satellite image showing the Allan Hills Main Icefield and the area covered by the north and south sections of the meteorite location maps. Locations of slope profiles are also shown.

## ALLAN HILLS MAIN ICEFIELD

The Allan Hills Main Icefield is located immediately west of the Y-shaped Allan Hills nunatak (Fig. 2). Approximately 75 km<sup>2</sup> of ice is exposed on this northward-trending icefield. Nearly 22 km long and 7.5 km at the widest point, this icefield has yielded approximately 1200 named meteorites. Figure 3 shows the area covered by the Main Icefield map sheets and the locations of two slope profiles (Fig. 4). *Annexstad* (1983) and *Faure and Buchanan* (1987) provide detailed descriptions of the Main Icefield area, and attempt to explain the meteorite concentration mechanism(s). *Delisle et al.* (1989) conducted a radio-echo sounding survey across the Main Icefield.

The Allan Hills Main Icefield was the first meteorite concentration locality found in the Transantarctic Mountains. At the close of the 1976–1977 field season a helicopter reconnaissance visit resulted in the recovery of 45 specimens representing 9 individual meteorites. Detailed foot searches in the next two seasons produced nearly 560 specimens. Eighty-five specimens were recovered in random searches during visits to the Main Icefield in the 1979–1980 and 1980–1981 seasons. Systematic searching was continued during the 1981–1982 season when nearly all the exposed ice area of the Main Icefield was searched in detail or visited on reconnaissance traverses, resulting in the recovery of 261 specimens. Brief periodic return visits by ANSMET expeditions have resulted in additional finds in the 1983–1984 (28), 1984–1985 (35), 1985–1986 (17), 1986–1987 (13), 1987–1988 (6), and 1990–1991 (6) seasons. During the 1988–1989 season a German expedition (GANOVEX) conducting radio-echo sounding studies in the area recovered 163 specimens from the Main Icefield (*Delisle et al.*, 1989). These meteorites were transferred to the EUROMET group for curation. Table 2 is a tabulation of types of meteorites and their numbers from the Allan Hills Main Icefield.

Yanai's meteorite location map (1984) shows the locations of meteorites recovered during the 1976–1977, 1977–1978, and 1978–1979 seasons. With certain exceptions, detailed in the next paragraphs, the specimens recovered from the Main Icefield in the following seasons for which we have reliable location data are plotted on the Allan Hills Main Icefield Meteorite Location Map, North and South Sections. Because of the size of the icefield and the high density of meteorite specimens, two map sections had to be produced. Reduced-scale examples of the North and South map sections are shown in Figs. 5 and 6. The maps are plotted in the UTM (zone 57) projection at a scale of 1:10,000. Grid cells are at 1-km intervals.

A small number of meteorites have been found in the vicinity of the Allan Hills or on the Main Icefield areas not covered by the map sections. One specimen (ALH 84243) was found on bedrock in Man Haul Bay, far removed from any ice (Fig. 3). Only one meteorite has been found on the ice in Man Haul Bay (see Yanai, 1984). Seven meteorites (ALHA 81037, ALHA 81093, ALHA 81100, ALH 84056, ALH 84071, ALH 84101, and ALH 85122) have been found on ice during random traverses and searches north of the mapped area. Other meteorites have been found on outcrop, apparently stranded by retreating ice. Three specimens (ALH 85037, ALH 85048, ALH 85123) were found on bedrock 2–4 m above the present ice surface near the south end of the icefield.

Most of the meteorite locations on the Main Icefield have been referenced to the survey network established by *Nishio and Annexstad* (1979) or to surveyed geographic features. Field note and sketch map data were used to document the locations of meteorites found during the 1979–1980 and 1980–1981 seasons. Crude locating or surveying methods (pelorus and snowmobile odometer) were used in the 1981–1982 season. In the 1983–1984 season we began to use a theodolite and EDM to precisely survey meteorite locations. The locations of the 1986–1987 meteorites were obtained from sketch map data provided by G. Faure. All meteorites that were not surveyed with the theodolite/EDM were plotted on a hand-drawn base map. The data points were then digitized along with the geographic features. The map was generated from merged databases of digitized and computed meteorite locations. Therefore, even though most of the meteorite locations not derived from the theodolite/EDM survey are not precisely determined, the locations of those meteorites found within a given season are accurately shown relative to one another. Since there are many precise control stations, the meteorite locations determined by the different location methods can be constrained so that the map accurately shows the distribution of meteorites on the icefield.

Several updated editions of the meteorite location maps have been produced since 1987. The latest edition (1993) of the Main Icefield meteorite location maps corrects the improper placement of several meteorites from the 1988 collection (ALH 88024, ALH 88054, and ALH 88135) and adds two meteorites for which data were not available earlier (ALH 88051 and ALH 88052). Icefield features were redigitized with better techniques.

For additional information on the meteorites from the 1988 collection, refer to *Meteoritical Bulletin* 69, 70, and 72 (Wlotzka, 1990, 1991, 1992).

TABLE 2. Tabulation of meteorite types from the Allan Hills Main Icefield (1979–1990 collections).

**Acknowledgments:** We thank J. Annexstad, F. Nishio, and L. Rancitelli (1979–1980); J. Annexstad, H. McSween, L. Rancitelli, L. Schultz (1980–1981); G. Crozaz, R. Fudali, and U. Marvin (1981–1982); R. Fudali, A. C. Hitch, K. Nishiizumi, P. Pellas, L. Schultz, and P. Sipiera (1983–1984); C. King-Frazier, S. Sandford, R. Score, R. Walker, and C. Thompson (1984–1985); L. Schultz, E. Zinner, and M. Zolensky (1985–1986); S. Iveson, M. Jackson, S. Traub-Metlay, and P. Wasilewski (1990–1991) for their contributions to the Allan Hills Main Icefield Meteorite Location Map. We also thank D. Buchanan, G. Faure, E. Hagen, and M. Strobel for contributing to the Main Icefield meteorite collection and mapping project in the 1986–1987 season. Their efforts were supported by NSF Grant DPP 83-14136. L. Schultz provided location data for meteorites recovered in the 1988–1989 season. We appreciate the continuity of effort by J. Annexstad, G. Delisle, L. Schultz, and J. Sievers in determining the positions of the meteorites recovered by the GANOVEX expedition.

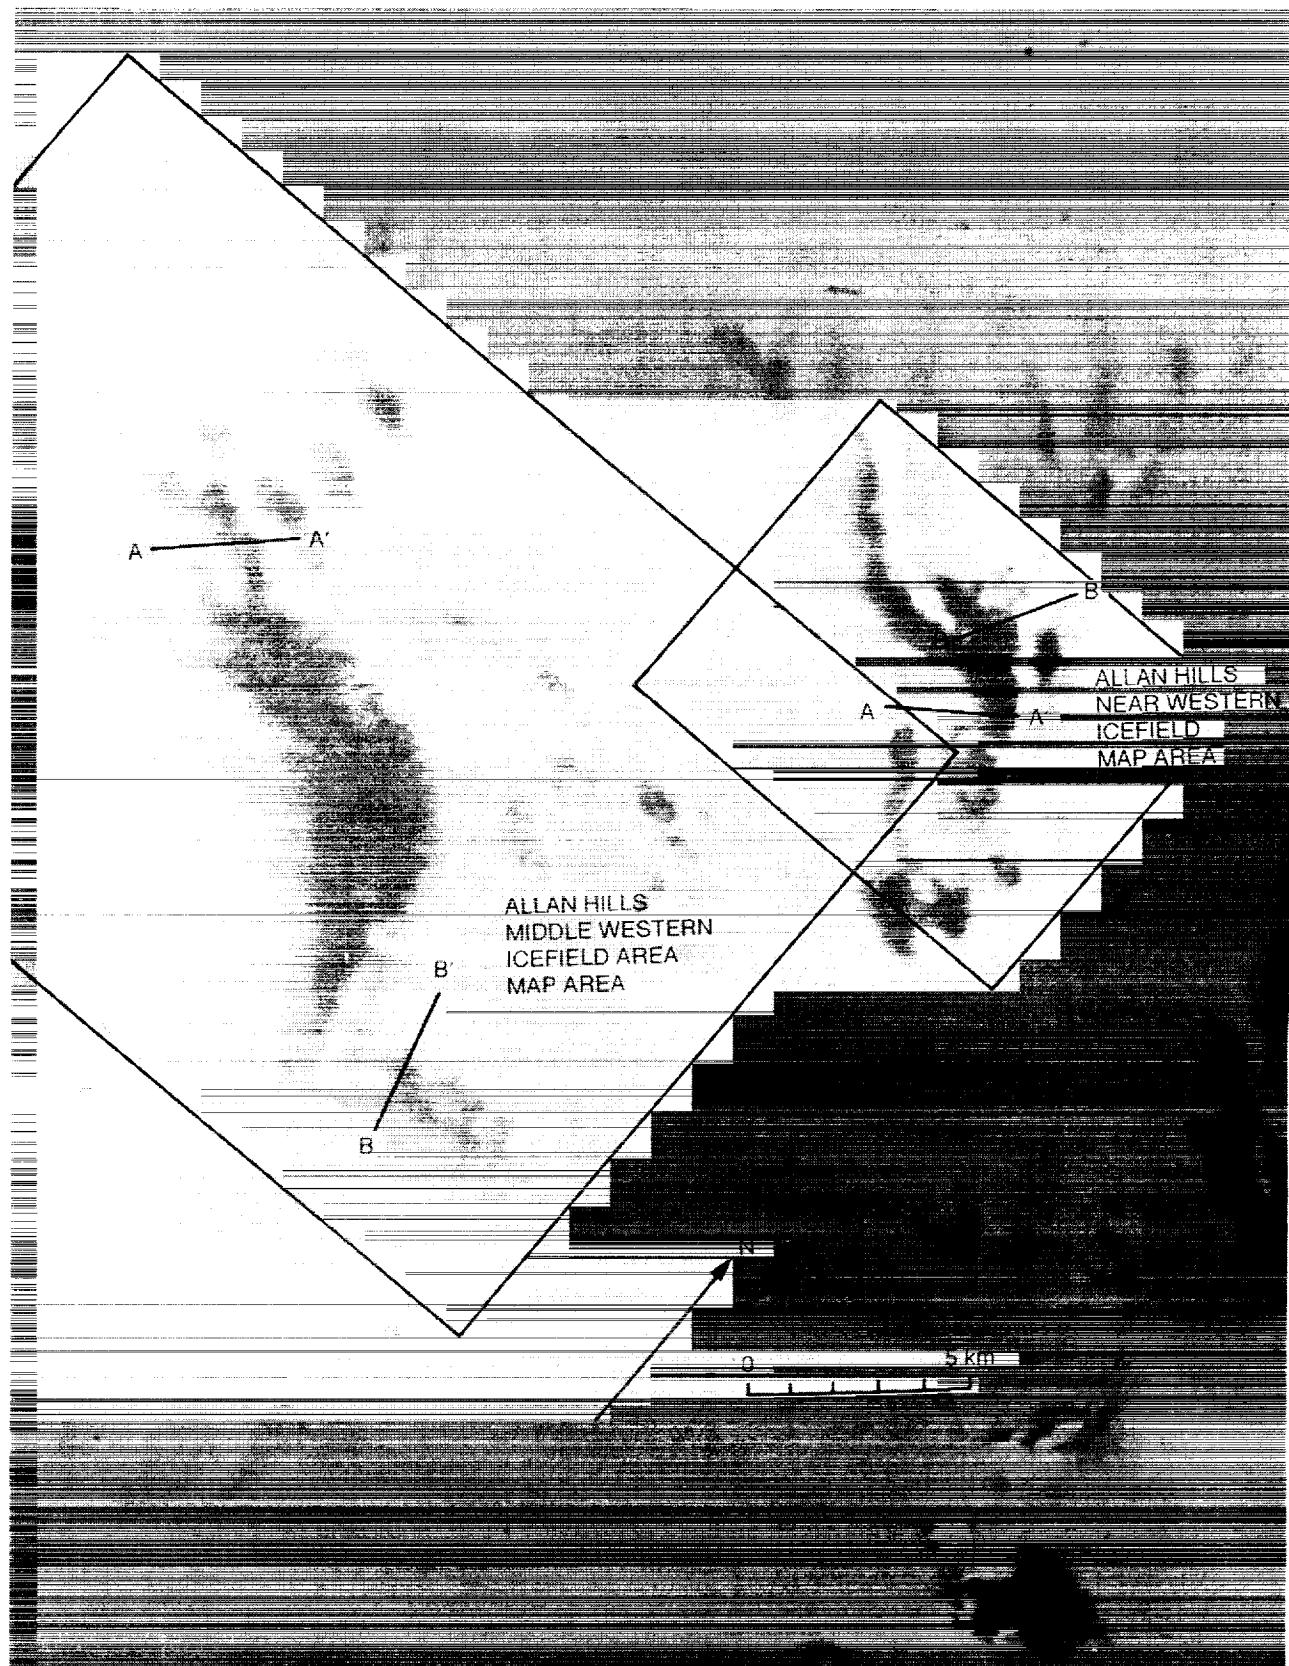

Fig. 7. Enlarged portion of satellite image showing the Allan Hills Near Western Icefield and the Middle Western Icefield and the area covered by the respective meteorite location maps. Location of slope profiles are also shown.

## ALLAN HILLS NEAR WESTERN ICEFIELD

The Allan Hills Near Western Icefield ( $76^{\circ}44'S$ ,  $158^{\circ}48'E$ ) lies approximately 12 km west of the Main Icefield (Fig. 2). This northwest-trending icefield is nearly 14 km long and up to 4 km wide. All areas of exposed ice have been systematically searched, and outliers and peripheries visited on a reconnaissance basis. Figure 7 shows the area covered by the Near Western Icefield map and the location of the two slope profiles diagrammed in Fig. 8.

During the 1977–1978 season, 21 meteorites were recovered from the Near Western Icefield. The location map published by Yanai (1984) gives the names and indicates the locations of these specimens. Since these specimens are not referenced to our survey base station network they are not included on our map. The positions of the 162 meteorites recovered from the Near Western Icefield during the 1981–1982, 1983–1984, 1984–1985, and 1988–1989 seasons are plotted on the Allan Hills Near Western Icefield Meteorite Location Map. A reduced version of the map is given as Fig. 9. Table 3 is a tabulation of meteorite types and their numbers from the Allan Hills Near Western Icefield.

Crude location methods were used during the 1981–1982 season. Most of the specimens found in subsequent seasons were surveyed using the more precise theodolite/EDM system. A preliminary location map was generated using survey data. The data from the 1981–1982 season were then “fitted” to a preliminary map and UTM coordinates scaled off, entered into the database, and a new location map was generated. Therefore, the map depicts accurately the relative locations of meteorites found in the same season, but somewhat less precisely the locations of specimens from different seasons. The map of the Allan Hills Near Western Icefield is plotted at a scale of 1:12,500 in the UTM (zone 57) projection. The grid cells are at 1-km intervals.

Three editions of the location map have been produced. The 1987 version had minor formatting and cosmetic changes and ALHA 81316 was added to the map and the database. The 1990 edition has the locations of the meteorites recovered by the 1988–1989 German GANOVEX expedition in the course of a radio-echo sounding survey (Delisle, 1989). These meteorites are curated by the EUROMET group. In the meteorite listing, under Newsletter, the *Meteoritical Bulletin* citation is given for the 1988 collection (Wlotzka, 1990, 1991, 1992).

The location of ALH 88043 is in error on the latest

version of the map. The actual UTM coordinates should be 1484363N 493325E. This will be corrected in future versions.

TABLE 3. Tabulation of meteorite types from the Allan Hills Near Western Icefield (1977, 1981, 1983, 1984, and 1988 collections).

**Acknowledgments:** We thank G. Crozaz, R. Fudali, and U. Marvin (1981–1982); R. Fudali, A. C. Hitch, K. Nishiizumi, P. Pellas, L. Schultz, and P. Sipiera (1983–1984); C. King-Frazier, S. Sandford, R. Score, C. Thompson, and R. Walker (1984–1985) for their contributions to the Allan Hills Near Western Icefield Meteorite Location Map. L. Schultz provided location data for meteorites recovered in the 1988–1989 season. We appreciate the continuity of effort by J. Annexstad, G. Delisle, L. Schultz, and J. Sievers in determining the positions of the meteorites recovered by the GANOVEX expedition.

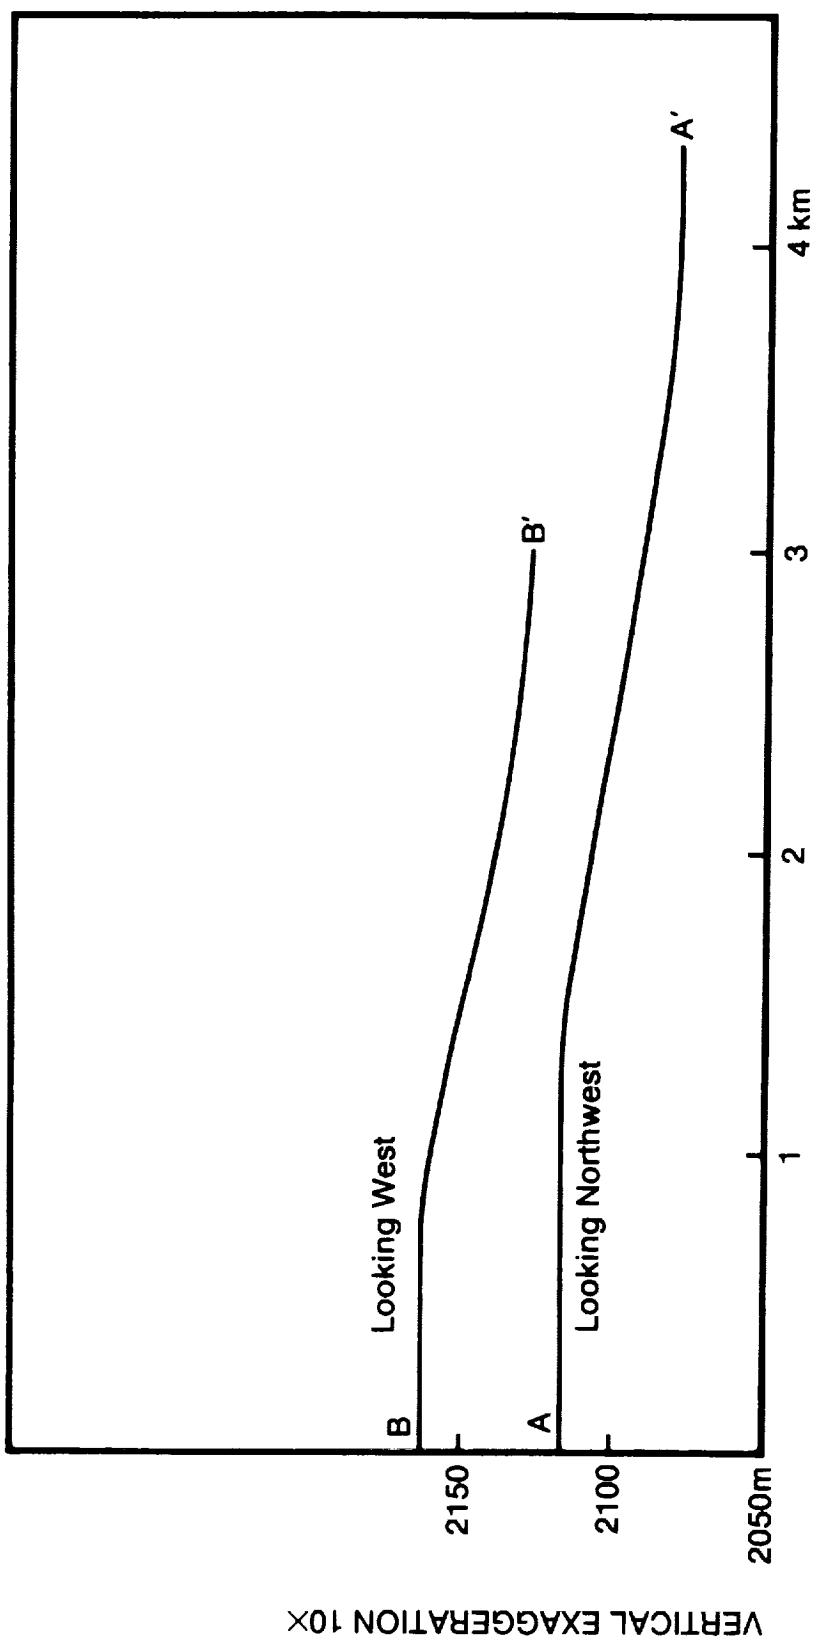

Fig. 10. Slope profiles of the Allan Hills Middle Western Icefield.

## ALLAN HILLS MIDDLE WESTERN ICEFIELD

The Allan Hills Middle Western Icefield ( $76^{\circ}50' S$ ,  $158^{\circ}26'E$ ) is situated approximately 25 km southwest of the Allan Hills Main Icefield (Fig. 2). This northwest-trending icefield is nearly 20 km long and up to 3.5 km wide. Approximately  $30 \text{ km}^2$  of ice is exposed. Figure 7 shows the area covered by the Middle Western Icefield map and the location of two slope profiles diagrammed in Fig. 10.

Five meteorites were reportedly recovered from the Middle Western Icefield on a helicopter reconnaissance search during the 1978–1979 season. No field numbers or location information were recorded for these specimens. The positions of the 80 meteorites recovered from the Middle Western Icefield during the 1981–1982, 1983–1984, and 1984–1985 seasons are plotted on the Allan Hills Middle Western Icefield Meteorite Location Map. A reduced scale version of the map is given as Fig. 11. One meteorite, ALH 87906, was recovered from the northernmost ice patch at the northwest end of the icefield area during a brief visit by an ANSMET expedition during the 1987–1988 field season. The location for this meteorite was not determined and does not appear on the map. Table 4 is a tabulation of types of meteorites and their numbers from the Allan Hills Middle Western Icefield.

Most of the meteorite locations on the Middle Western Icefield were determined using theodolite/EDM methods. Thus, the relative locations of specimens found and surveyed in different seasons is precisely shown.

The map of the Allan Hills Middle Western Icefield is plotted at a scale of 1:25,000 in the UTM (zone 57) projection. The grid crosses are spaced 2 km apart. Two earlier editions of the Allan Hills Middle Western Icefield Meteorite Location Map have been produced. The second, or 1987, edition has only minor formatting and cosmetic enhancements and no additions or deletions of meteorite locations.

## ALLAN HILLS FAR WESTERN ICEFIELD

The Allan Hills Far Western Icefield ( $76^{\circ}54'S$ ,  $157^{\circ}01'E$ ) is a large bare ice area lying approximately 70 kilometers southwest of the Allan Hills (Fig. 2). This sinuous icefield, trending northwest, is nearly 45 km long and up to 8 km across at its widest point. Approximately 100  $\text{km}^2$  of ice is exposed. Figure 12 shows the area covered by the meteorite location maps and indicates the location of three slope profiles (Fig. 13).

The Far Western Icefield was first visited during the 1982–1983 season. Systematic searches were made in selected areas and 45 meteorites were recovered. One meteorite (ALH 82102) was discovered in the process of emerging from the ice as the surface was ablating. A satellite surveying instrument was employed during this season to determine three base station locations used in the meteorite location surveys. These points potentially can be used in the study of ice movement rates. A brief visit was made during the 1983–1984 season, mainly to collect ice samples and begin the survey traverse that connected all the Allan Hills icefields. Systematic searches of virtually the entire blue ice area were made in the following two field seasons. During the 1990–1991 season the southeastern end of the Far Western Icefield was visited for the purpose resurveying ice motion points using satellite positioning methods. Some of the areas systematically searched in previous seasons were again searched in detail. Nine additional meteorites were recovered. Table 5 is a tabulation of types of meteorites and their numbers from the Allan Hills Far Western Icefields.

The positions of the 326 named meteorites collected from the Far Western Icefield are plotted on the Allan Hills Far Western Icefield Meteorite Location Map. Because of the desired map scale and the size and orientation of the icefield, two map sections had to be generated. These are designated the West and East sections. Figure 12 shows the areas covered by the map sections. Figures 14 and 15 are reduced versions of the two map sections. The map is plotted at a scale of 1:25,000 in the UTM (zone 57) projection. The UTM grid cell crosses are spaced 2 km apart.

Crude surveying methods were used to determine meteorite positions during the 1982–1983 season. In subsequent seasons most of the meteorite locations and the 1982–1983 base stations were surveyed with the theodolite and EDM. Thus, the relative locations between the 1982–1983 specimens and all the others are not precise. The locations of eight meteorites (ALH 82109, ALH 82116, ALH 82137, ALH 83105, ALH 83108, ALH 84221, ALH 85004, and ALH 85012) were determined only very generally, and placements on the map are therefore approximate. In the 1983–1984 season two carbonaceous chondrite scatter fields were found near the southern end of the icefield. In

the larger of the two, 56 fragments were recovered. These have been paired, and are named ALH 83100. The general outline of this scatter field is shown on the map. The location of ALH 83102 was the site of a smaller scatter field consisting of 21 paired fragments. It was located approximately 50 m from the larger one and both sets of specimens probably are parts of the same pairing group.

Different editions of the Allan Hills Far Western Icefield Meteorite Location Map have been generated. The following changes were made on the 1987 edition, East and West sections:

- Minor format and cosmetic changes.
- Deletion of the ALH 85116 specimen location, which turned out to be a terrestrial rock.
- Correction of the ALH 83100 strewn field designation in the legend and addition of ALH 83100 to the map.
- Elimination of the 7.5-cm overlap between the East and West sections.

An updated edition (1991) of the East map section, which includes the 1990 collection, was produced. No up-

date was required for the West section since this area was not visited during the 1990–1991 season.

**Acknowledgments:** We thank T. Meunier and C. Thompson (1982–1983); R. Fudali, A. C. Hitch, K. Nishizumi, P. Pellas, L. Schultz, and P. Sipiera (1983–1984); C. King-Frazier, S. Sandford, R. Score, C. Thompson, and R. Walker (1984–1985); L. Schultz, E. Zinner, and M.

Zolensky (1985–1986); S. Iveson, S. Traub-Metlay, and P. Wasilewski for their contributions to the Allan Hills Far Western Icefield Meteorite Location Map. T. Meunier of the U.S. Geological Survey provided location data for the 1982–1983 meteorites and satellite positioning-derived base station coordinates.

**Fig. 12.** Enlarged portion of satellite image showing the Allan Hills Far Western Icefield and the area covered by the east and west sections of the meteorite location maps. Dotted line is overlap area of 1986 map editions. Locations of slope profiles are also shown.

## ELEPHANT MORaine METEORITE LOCATION MAP SERIES

What has become known as the Elephant Moraine area of the Allan Hills–David Glacier region actually comprises a series of large, discontinuous, and separate bare ice areas in the vicinity of the Elephant Moraine ( $76^{\circ}11'S$ ,  $157^{\circ}10'E$ ) (Fig. 2). Meteorites that have been recovered from these areas have all been named with prefix EET in the same way that, for example, the meteorites from the Far Western Icefield have been designated as ALH meteorites. Meteorites have been found on many of these icefields, sometimes in high concentrations. As a result, we have given informal names to some of these local areas with high meteorite densities. Meteorite location maps have been produced for two areas that so far have been searched in detail: the area in the immediate vicinity of Elephant Moraine and an icefield known as Texas Bowl. The areas covered by the Elephant Moraine–Elephant Moraine Icefield Meteorite Location Map and the Elephant Moraine–Texas Bowl Meteorite Location Map are shown in Fig. 16. Other icefields, such as the Meteorite City area, have produced significant numbers of meteorites. Meteorite locations have been determined there, but maps of these areas will not be produced until systematic searches have been completed.

Most of the Elephant Moraine icefields are colinear and are associated with an ice escarpment extending westward from Reckling Peak for 100 km. A large bare ice area 35 km northwest of Elephant Moraine is not colinear with this system. We have called it the Elephant Moraine Northern Ice Patch, and it does not appear to be directly associated with the Reckling Moraine–Elephant Moraine escarpment. The topography is complex along these features, with many escarpments, steps, and basins. Elephant

Moraine itself is an unusual, isolated surficial moraine lying along the escarpment (Fig. 2). No other moraines are present in the area that we refer to as the Elephant Moraine icefields.

Meteorites were first discovered on the ice immediately surrounding Elephant Moraine during a reconnaissance traverse in the 1979–1980 season (Cassidy, 1980). Systematic searches of the area and brief visits by ANSMET expeditions and others resulted in numerous recoveries during the 1982–1983, 1983–1984, 1984–1985, 1986–1987, and 1987–1988 field seasons. During the 1982–1983 season a reconnaissance trip was made to the icefields located 20–35 km west of Elephant Moraine. From this area six meteorites (EET 82604, EET 82609, EET 82610, EET 82614, EET 82615, and EET 82616) were recovered. The Northern Ice Patch was also briefly visited and two meteorites (EET 82608 and EET 82612) were collected.

The 1987–1988 ANSMET expedition conducted comprehensive reconnaissance surveys west and north of Elephant Moraine that included detailed searches of local areas in Texas Bowl, Meteorite City, and at the Northern Ice Patch. During the 1992–1993 field season the Northern Ice Patch was completely searched. Only preliminary editions of the Elephant Moraine–Northern Ice Patch Meteorite Location Map are available at this time. Since this field season has only recently been completed, no meteorites have been characterized and thus no text is included in this report.

Note that the meteorite listings for the Elephant Moraine and Texas Bowl map areas only include those EET specimens that were found within the map area or general vicinity.

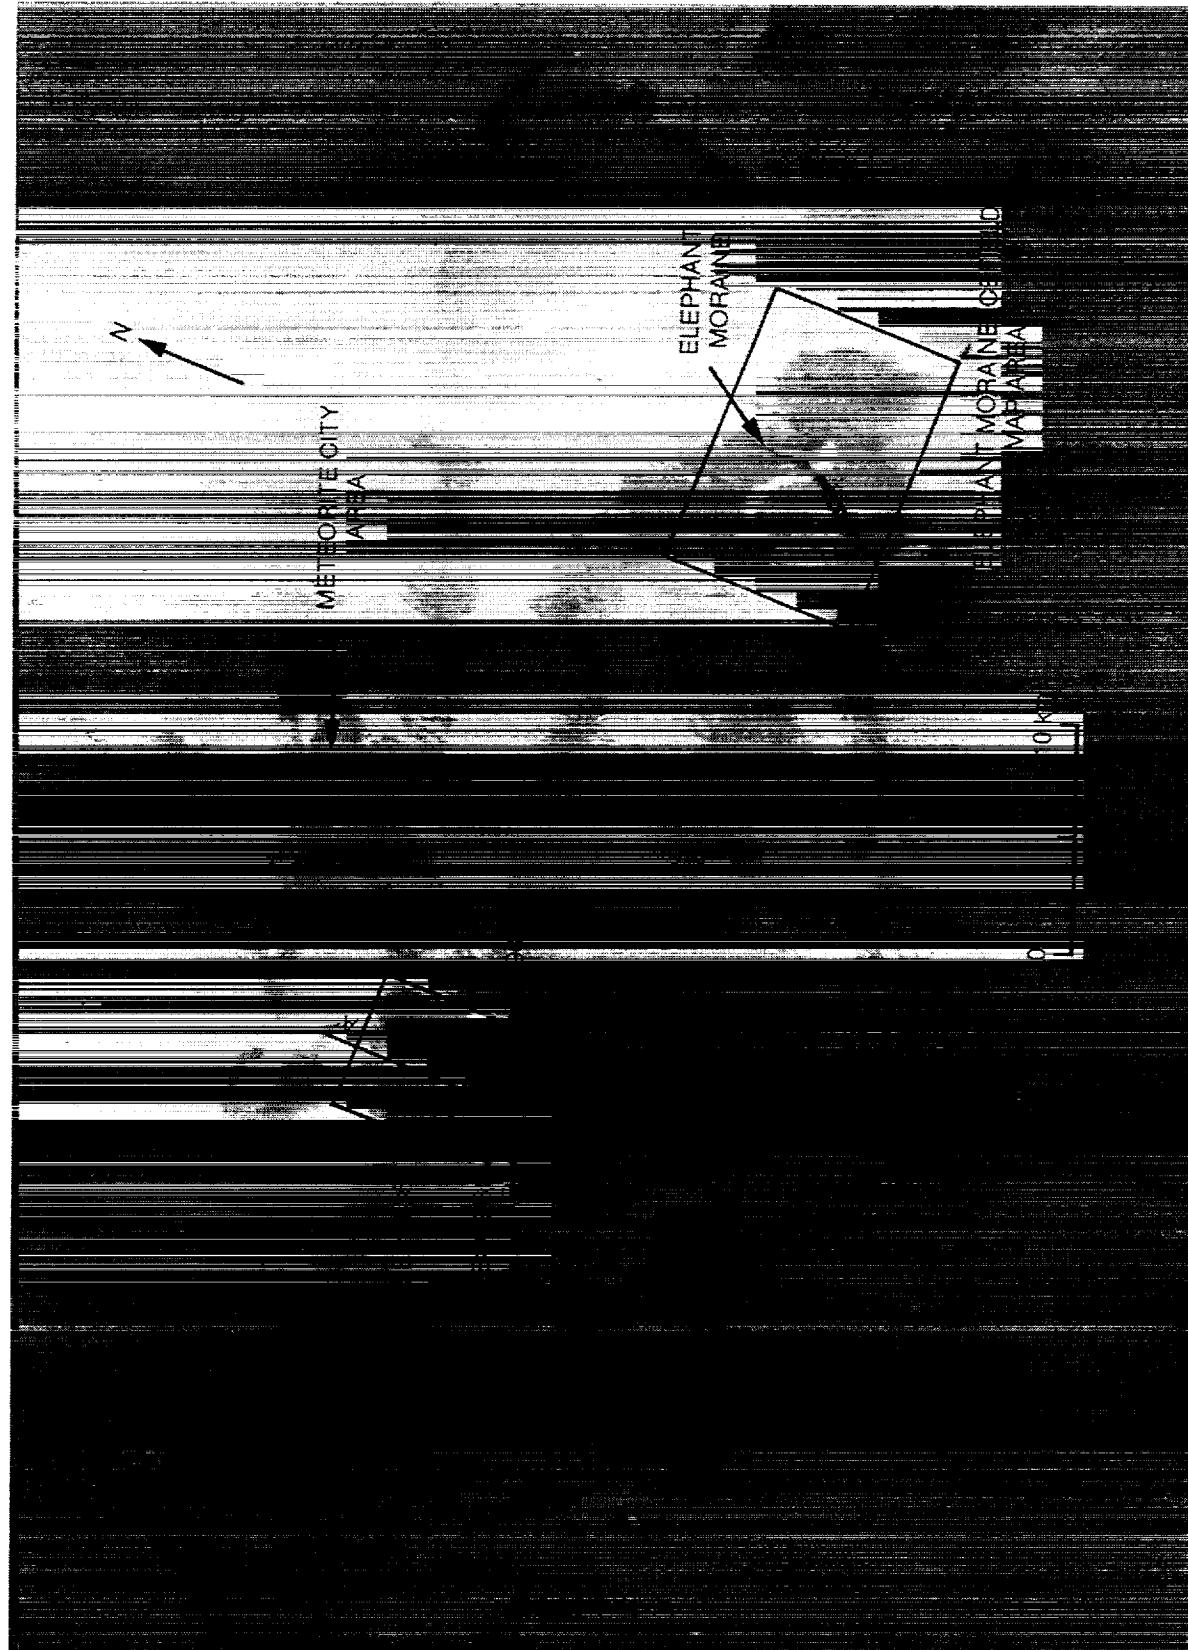

Fig. 16. Enlarged portion of a satellite image showing part of the Elephant Moraine Icefield area. Areas covered by the Elephant Moraine–Elephant Moraine Icefield Meteorite Location Map and the Elephant Moraine–Texas Bowl Meteorite Location Map are indicated. Location of the slope profile in the Texas Bowl area is also shown, as well as the locations of the meteorites from the Texas Bowl area not within the meteorite location map area.

## ELEPHANT MORaine-ELEPHANT MORaine ICEFIELD

Elephant Moraine is an unusual, isolated, surficial moraine not associated with exposed bedrock, which lies along an escarpment running westward from Reckling Peak (Fig. 2). Bare ice areas surround the moraine. In the vicinity of the moraine, upwards of 50 km<sup>2</sup> of ice is exposed. Elephant Moraine consists of a thin veneer of rocks lying on ice. The moraine tails out toward the north, normal to the escarpment and following the ice flow toward the David Glacier (Fig. 17). Elephant Moraine and the similar Reckling Moraine have been the focus of studies by Faure and co-workers (*Faure and Taylor, 1985; Faure et al., 1987*).

Ten meteorites were collected on a reconnaissance visit to Elephant Moraine in the 1979–1980 field season. A brief period during the 1982–1983 season was spent in systematic searching. Virtually the entire bare ice area covered by the location map was systematically searched or visited on a reconnaissance basis during the 1983–1984 season. Small collections were made in the 1984–1985 and 1986–1987 seasons by the parties studying the moraine. During the 1987–1988 season the area around the moraine was again visited and 35 meteorites were recovered from the area covered by the Elephant Moraine–Elephant Moraine Icefield Meteorite Location Map. Table 6 is a tabulation of types of meteorites and their numbers from the Elephant Moraine Icefield.

The locations of 261 of the 263 meteorites collected from the vicinity of Elephant Moraine in the 1979–1980, 1982–1983, 1983–1984, 1984–1985, and 1986–1987 seasons are plotted on the Elephant Moraine–Elephant Moraine Icefield Meteorite Location Map. The area covered by the map is shown in Fig. 16. A reduced-scale example of the map is shown in Fig. 18. The map is plotted at a scale of 1:12,500 in the UTM (zone 57) projection. The grid crosses are on 1 km spacings. Three editions of the map have been produced. The following changes have been made to the 1987 edition:

- Addition of the three 1986 specimens.
- Deletion of terrestrial samples EET 83313, EET 83327, EET 83332, and EET 83381 from the map and meteorite databases.
- Addition of EET 83403 to the map and meteorite databases.
- Combined location of two mapped fragments of EETA 79007 to one representative location.
- Minor format and cosmetic enhancements.

The 1991 edition includes the 1987 meteorite collection.

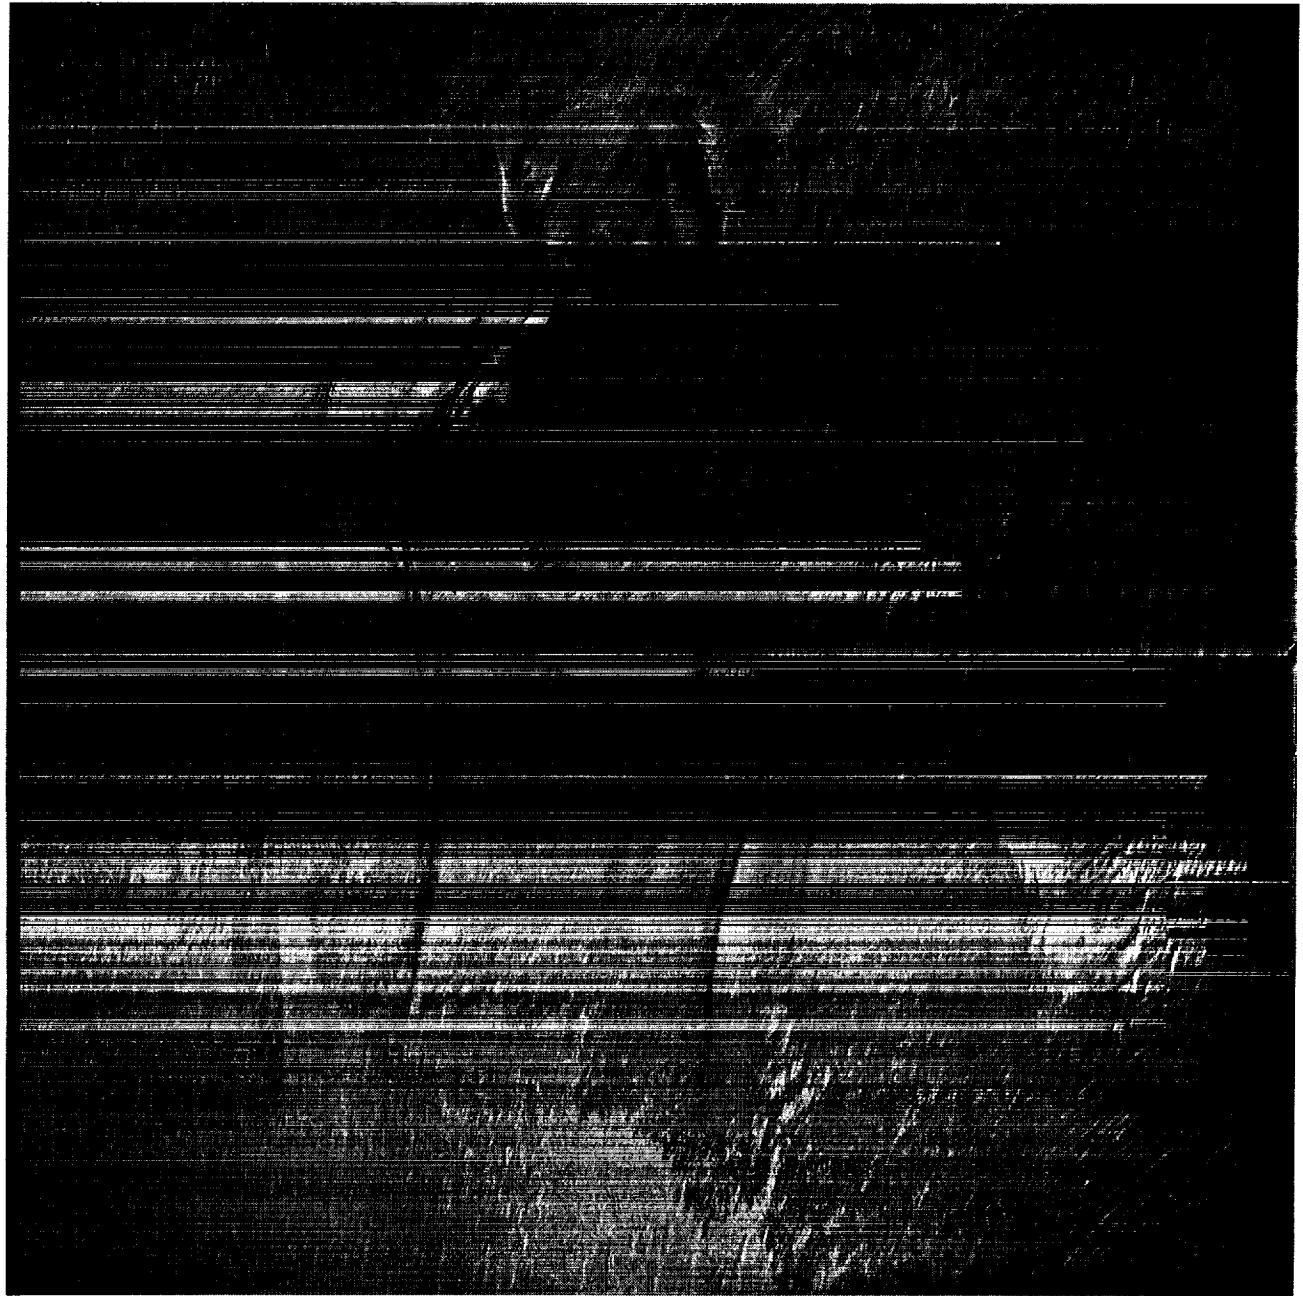

The locations of meteorites found on the 1979–1980 reconnaissance trip were plotted approximately on aerial photographs. The locations of meteorites found in succeeding seasons were determined by a variety of surveying methods. Thus, only the relative positions of meteorites found within a given season are shown accurately. A theodolite and EDM were used to establish precise control po-

sitions of the 110, 115, and Elephant stations relative to the satellite-surveyed Dr. Seuss base station.

TABLE 6. Tabulation of meteorite types from the Elephant Moraine–Elephant Moraine Icefield 1979, 1982, 1983, 1984, and 1987 collections.

?No meteorite position was determined or location information was recorded. See text.

## ELEPHANT MORaine-TEXAS BOWL ICEFIELD

The Texas Bowl Icefield area of the Elephant Moraine Icefield complex has proved to be one of the densest concentrations yet discovered, with 1212 specimens recovered from a restricted 15-km<sup>2</sup> area. This local bare ice patch lies 26 km west-northwest of Elephant Moraine and is a continuation of the Reckling Moraine-Elephant Moraine ice escarpment feature (Fig. 2). Figure 16 shows the main portion of the Elephant Moraine Icefield complex and the part of that area covered by the Texas Bowl Icefield Meteorite Location Map. Figure 19 shows a slope profile across the Texas Bowl Icefield.

Meteorites were first found in the Texas Bowl Icefield area during reconnaissance and systematic searches in the 1987-1988 field season (Huss *et al.*, 1988). A total of 185 specimens was recovered. During the 1990-1991 season the entire bare ice area covered by the Elephant Moraine-Texas Bowl Icefield Meteorite Location Map was systematically searched, yielding 1027 meteorite specimens. Only two meteorites from this collection, EET 90488 and EET 90350, fall outside the Texas Bowl map area; Fig. 16 indicates the locations of these two specimens.

The Elephant Moraine-Texas Bowl Meteorite Location Map is plotted in the UTM (zone 57) projection at a scale of 1:5000. Figure 20 is a reduced version of the Elephant Moraine-Texas Bowl Icefield. The meteorites have been given a grid cell address based upon the UTM grid. The UTM grid cells are spaced 500 m apart. All meteorite positions within the map area were determined using conventional surveying methods. A Magnavox MX-1502 TRANSIT satellite surveying instrument was used to determine the position of two baseline survey stations by translocation from an established survey point occupied by another field project in the region.

As can be seen from the meteorite listing and Table 7, a high percentage of meteorite samples from Texas Bowl are L-6 chondrites. This may be an example of a meteorite shower that has been reconcentrated by glacial motion. Since it was apparent that many of these were paired, a number of samples were arbitrarily paired at JSC without regard to their spatial distribution. As a result, the name EET 90053 has been assigned to a number of specimens that are spread over a wide area of the icefield. EET

90053,0 is the farthest north and most downwind of the chosen fragments. This is significantly different from all other situations where multiple specimens are paired and given the same name.

## BEARDMORE GLACIER REGION METEORITE LOCATION MAP SERIES

The Beardmore Glacier region of the Transantarctic Mountains contains numerous meteorite stranding surfaces and meteorite finds. The area was first explored for meteorites during the 1985–1986 field season (*Cassidy et al.*, 1986; *Cassidy*, 1992). In the upper reaches of the Beardmore Glacier and Mill Glacier drainage system, meteorites were found on icefields in the Dominion Range and the Grosvenor Mountains areas. Sketch maps showing the meteorite locations have been produced for these areas (*Cassidy*, 1992) and are included in this report. The Queen Alexandra Range lies west of the Beardmore Glacier. Meteorite stranding surfaces have been found along the southwestern edge of the range and at the head of the Walcott Névé. A meteorite location map of the Goodwin Nunataks area of the Queen Alexandra Range has been produced and is currently available, even though the area is incompletely searched. Further along the western side of

the Walcott Névé lies the Lewis Cliff area. This is the largest meteorite stranding site in the area and the most thoroughly searched icefield to date. A total of 1752 meteorite specimens have been collected from the Lewis Cliff icefields. Three meteorite location maps have been produced for the Lewis Cliff meteorite stranding surfaces. West of the Lewis Cliff, at the head of the Law Glacier, significant numbers of meteorites have been produced from icefields in the MacAlpine Hills area. A meteorite location map for the MacAlpine Hills area will not be produced until the area has been completely and systematically searched. The location of these areas and the areas covered by the published meteorite location maps are shown on Fig. 26. One meteorite, BOW 85800, has been found on the Bowden Névé of the Law Glacier and is approximately located in Fig. 21.

**Fig. 22.** Map 1: Locations of meteorites found in the Dominion Range area, Beardmore region.

## DOMINION RANGE AND GROSVENOR MOUNTAINS ICEFIELDS

The Grosvenor Mountains ( $85^{\circ}40'S$ ,  $175^{\circ}00'E$ ) and the Dominion Range ( $85^{\circ}20'S$ ,  $166^{\circ}30'E$ ) are relatively small groups of mountains and nunataks situated at the head of the Beardmore Glacier. Many bare ice areas are adjacent to the nunataks and along other ice escarpments. The area is covered by the 1:250,000-scale U.S.G.S. Plunket Point quadrangle. The upper reaches of the Beardmore Glacier were explored for meteorites during the 1985–1986 field season. A full account of the activities from that season can be found in *Cassidy* (1992). Thirty-two meteorites were found in widely scattered areas. Figure 22 shows the area explored by the field team and their traverse route.

The locations of the meteorites were not determined by survey or GPS methods and must therefore be considered approximate.

Sketch maps, with meteorite locations indicated, are found in Figs. 23–26. These maps, originally published in *Cassidy* (1992), have been corrected based upon information that became available subsequent to when the original maps were produced. The meteorite listing indicates on which maps the specimen locations can be found.

**Acknowledgments:** P. Englert, T. Thomas, and C. Thompson were involved in the 1985–1986 reconnaissance searches.

## QUEEN ALEXANDRA RANGE-GOODWIN NUNATAKS AREA

The Queen Alexandra Range is an impressive range of mountains situated in the Beardmore Region of the Transantarctic Mountains with peaks rising to 4000 m. The Beardmore Glacier lies to the east and parallels the range; the Walcott Névé and Lewis Cliff areas are to the west. At the head of the Walcott Névé, some 40 km southeast of the Lewis Cliff Ice Tongue, is a series of ice patches, ice-cored moraines, and nunataks extending a distance of 15 km southwestward from the Queen Alexandra Range to the Goodwin Nunataks (Fig. 21). The ice escarpment along which these features are situated turns northward at Goodwin Nunataks and continues to the Lewis Cliff, marking an apparent cirque rim that defines the Walcott Névé. Figure 27 is an aerial photo of the Goodwin Nunataks area.

The Goodwin Nunataks area was first visited during a reconnaissance search in the 1986–1987 field season. Only one meteorite was recovered at that time, but many were seen. In the 1988–1989 season searches were made of bare ice in the Gordon Valley area along the eastern edge of the Walcott Névé, 32 km northeast of the Goodwin Nunataks. Two meteorites, QUE 88400 and QUE 88401, were discovered and collected. Their approximate locations are shown on Fig. 21. Systematic searching of the ice in the Goodwin Nunataks area began in the 1990–1991 season. A total of 86 meteorite specimens was recovered from the nunataks around the Foggy Bottom site (an informal name) and from the next series of ice patches to the northeast. To date the area has not been completely searched. Table 8 is a tabulation of types of meteorites and their numbers from the Queen Alexandra Range Icefields.

The Queen Alexandra–Goodwin Nunataks Meteorite Location Map is plotted at a scale of 1:20,000 in the polar stereographic projection. The area covered by the map is shown in Fig. 21 and a reduced example of the map is given in Fig. 28. The grid cells are defined by latitude and

longitude intervals of 1 minute of latitude and 10 minutes of longitude. All the meteorites recovered from the 1986–1987 and 1990–1991 seasons are plotted on the map. No ice/firn boundaries delineating the bare ice areas could be plotted due to the lack of appropriate air photos, satellite images, or ground control. The topographic contours and the moraine and outcrop areas were digitized from the 1:250,000-scale U.S.G.S. Buckley Island quadrangle, and are very generalized.

The locations of the meteorites were determined by using GPS receivers and averaging 30 fixes. The accuracies of these positions about  $\pm 20$  m at worst.

## LEWIS CLIFF ICEFIELDS

The icefields of the Lewis Cliff area have proved to be one of the most prolific meteorite stranding sites in the Transantarctic Mountains and one of the most difficult ones to search. Because of the high density of terrestrial rocks on the ice surface, two-thirds of what we refer to as the Lewis Cliff Ice Tongue was searched on foot over four field seasons. (It is interesting to note that the density of meteorites on the Ice Tongue correlates well with the area of highest terrestrial rock density.) Ice appears to flow off the polar plateau over the Lewis Cliff escarpment and into Walcott Névé. Some of this ice is funneled into the narrow channel of the Lewis Cliff Ice Tongue. Approximately 30–35 km<sup>2</sup> of ice is exposed in the Lewis Cliff area. About 2.5 km at its widest and approximately 8 km long, the Ice Tongue terminates against a vast expanse of undulating ice-cored moraines below Mt. Achernar. Figure 29 shows an aerial view of the Ice Tongue. A topographic step with 75-m relief divides the Ice Tongue into two sections, which we refer to as the lower Ice Tongue and the upper Ice Tongue. A north-south longitudinal profile down the center of the Ice Tongue is shown in Fig. 30.

One area of ice-cored moraine situated below a steep ice slope to the east of the Ice Tongue had abundant meteorite fragments intermixed with the terrestrial rocks. We refer to this area as Meteorite Moraine. To date, 259 meteorite fragments have been found within or immediately adjacent to the moraine and upwind of it. From the South Lewis Cliff Icefield, south and upstream of the Ice Tongue, 137 meteorite specimens were recovered. A scattering of meteorites was found on other smaller ice patches in the area. The locations of meteorites that were found either outside the area covered by the meteorite location maps or out of the survey area are indicated on Fig. 26. The listing is a tabulation of the 1752 meteorites from the Lewis Cliff icefields. All but two of the Lewis Cliff meteorites have been described and classified to date. Additional descriptions of the Lewis Cliff area can be found in *Cassidy et al.* (1992). Table 9 is a tabulation of meteorite types and their numbers from the Lewis Cliff Icefields.

Three meteorite location maps show the distribution of meteorites recovered during the 1985–1986, 1986–1987, 1987–1988, 1988–1989, and 1990–1991 field seasons from the Lewis Cliff stranding surfaces. The area covered by these maps is shown on Fig. 26 and reduced examples of the maps are given in Figs. 31–33. The maps are plotted in the polar stereographic projection. Except for the Meteorite Moraine specimens, nearly all the meteorites were surveyed using theodolite and EDM methods. Most of the meteorites from Meteorite Moraine were located relative to a local grid tied to the survey network.

### Lewis Cliff Ice Tongue Map, North and South Sections

Most of the meteorites recovered from the Lewis Cliff area have been found on the Lewis Cliff Ice Tongue. Because of the density of meteorite occurrence, two maps at a scale of 1:5000 were required to show the detail. The North Section map covers the lower Ice Tongue and the South Section the upper Ice Tongue. The "street map" grid cell feature is slightly different from other maps of areas farther north. On the Lewis Cliff maps, the grid cells are defined by geographic latitude and longitude instead of a metric UTM grid as those in the Allan Hills/David Glacier Region Map Series. The interval between the grid cells is 15 seconds of latitude and 2.5 minutes of longitude. The letter component of the grid cell designation for the two maps is prefixed by N or S depending on whether the meteorite is located on the North or South section maps. These letters are found on the left or right sides of the map and begin with NA at the top of the North Section Map and run continuously to SR at the bottom of the South Section Map. No names have been plotted for most of the meteorites found in the high-density occurrence at Meteorite Moraine. These meteorites are indicated by an asterisk next to the grid cell reference in the meteorite listing table.

### Lewis Cliff Area Map

The Lewis Cliff Area Meteorite Location Map shows the names and locations of meteorites found outside the area covered by the Lewis Cliff Ice Tongue, North and South Sections. Most of these were found on the South Lewis Cliff Icefield. This map is plotted at a scale of 1:20,000. The grid cell "distance" for this map is an interval of 1 minute of latitude and 10 minutes of longitude. The grid cell letter designations are prefixed with an A to separate them from the N (north) and S (south) designations of meteorites found on the Ice Tongue maps. Therefore, if a meteorite has a grid cell designation of AE-4 it can be found on the Area Map. If it has an NF-4 it will be found on the Ice Tongue, North Section Map. None of the names of meteorites found on the Ice Tongue maps are plotted, but all locations of those meteorites are indicated.

One meteorite, LEW 87016, actually consisted of two specimens found approximately 195 m apart. The name LEW 87024 was originally given to the northerly, or downwind specimen. This is shown on the present map edition. Subsequently the samples were paired and a common name, LEW 87016, was given. No weight data for each individual specimen was preserved. Therefore the name of

2	Metal fragment
1	Metal from H chondrite
1	Shergottite
10	Ureilite
1752	Total

the meteorite is duplicated as LEW 87016,0 and LEW 87016,0 as is shown in the meteorite listing and the database. The duplicate name will be indicated as such on future editions of the map. The total mass of the combined specimens is 16.8 g.

**Acknowledgments:** We thank ANSMET field party members P. Englert, T. Thomas, and C. Thompson who helped conduct the initial reconnaissance searches and mapping in the 1985–1986 season; A. Marden, L. Lindner, K. Yanai, and C. Koeberl (1986–1987); J. Fitzpatrick, R. Fudali, R. Harvey, and F. Vilas (1987–1988); D. Blewett, M. Grady, R. Harvey, R. Korotev, S. Sandford, and R. Score (1988–1989). We appreciate the contribution to the 1990 meteorite collection by G. Faure and E. Hagen. G. Parasso, E. Eckel, M. Hower, and G. Sandul of the U.S.G.S. established the primary survey stations in 1985–1986.

?No meteorite position was determined or location information was recorded. See text.

\*Specimen is from Meteorite Moraine and no name has been plotted.

<sup>†</sup>See Fig. 26 for locations.

<sup>‡</sup>See text for information regarding these specimens.

**Fig. 34.** Map of the Thiel Mountains region showing the location of the meteorites found along the Davies Escarpment and the area covered by the Moulton Escarpment Meteorite Location Map. Base maps are the U.S.G.S. 1:250,000-scale Thiel Mountains and Moulton Escarpment quadrangles.

## THIEL MOUNTAINS METEORITE LOCATION MAP SERIES

One of the earliest meteorite finds in Antarctica was from the Thiel Mountains (*Ford and Tabor*, 1971). The Thiel Mountains pallasite was found in the vicinity of Mount Wrather ( $85^{\circ}23'S$ ,  $87^{\circ}14'W$ ). Exploration for meteorite concentrations in that area failed to yield additional specimens or a concentration; however, meteorites were found along the Davies Escarpment, approximately 25 km westward, and at the Moulton Escarpment, 70 km to the northwest (*Schutt et al.*, 1983; *Schutt*, 1985). The area is covered by the U.S.G.S. 1:250,000-scale Thiel Mountains and Moulton Escarpment quadrangles. Figure 34 shows the general location of the Thiel Mountains pallasite. Also shown are the locations of the meteorites found along the Davies Escarpment and the area covered by the Moulton Escarpment Meteorite Location Map.

A total of seven meteorite specimens representing five meteorites were found along the Davies Escarpment, an ice escarpment some 70 km in length extending southward from the Bermel Escarpment. Blue ice areas of limited

extent are located at the north and south ends of the escarpment. At one point along the escarpment near Lewis Nunatak a small area of bedrock is exposed. Six specimens were found at the northern end and one was found mixed in with terrestrial rock near the south end. A listing of the Davies Escarpment meteorites is included below.

Listing of meteorites recovered from the  
Davies Escarpment icefields (1982 collection).

## MOULTON ESCARPMENT

The Moulton Escarpment trends east-west with outcrops rising above the ice for 4.5 km. This is the westernmost nunatak in the Thiel Mountains. Approximately 25 km<sup>2</sup> of ice is exposed in the area. Ice appears to flow from south to north. The larger ice areas are situated upstream and downstream of the escarpment, but smaller ice patches occur to the west and east along the ice escarpment. A number of ice-cored moraines are "stacked" below the escarpment. Figure 35 is a vertical aerial photograph mosaic of the Moulton Escarpment.

Reconnaissance during the 1982–1983 season failed to find meteorites on the upstream icefield. One meteorite was found on the isolated ice patch to the east. The rest of the meteorites were found in a restricted area below the escarpment and east of the ice-cored moraines. A total of 11 meteorite specimens were recovered in that season. A Twin Otter-supported team was able to visit the area briefly during the 1991–1992 season and systematically search the ice where this concentration was found. This resulted in another 25 finds. Table 10 is a tabulation of types of meteorites and their numbers from the Moulton Escarpment Icefield.

The Moulton Escarpment Meteorite Location Map is plotted at a scale of 1:10,000 in the polar stereographic projection. The grid cells are defined by latitude and longitude intervals of 30 seconds of latitude and 5 minutes of longitude. A reduced example of the map is given in Fig. 36.

All the meteorites recovered from the Moulton Escarpment are plotted on the map. The locations of specimens from the 1982 collection were surveyed using snowmobile

odometer and pacing for distance, and compass for relative bearings and triangulation. All the 1991 meteorites were located using a GPS receiver averaging 35–100 fixes.

## PECORA ESCARPMENT METEORITE LOCATION MAP SERIES, PECORA ESCARPMENT

The Pecora Escarpment, an isolated series of nunataks trending southeast-northwest, is situated at 85°38'S, 68°42'W. Figure 37 is an aerial view looking southward. Extensive bare ice areas of approximately 120 km<sup>2</sup> occur both on the upstream and downstream sides of the escarpment in the immediate vicinity of the nunataks. Meteorites have been recovered from nearly all these bare ice areas. Informal names have been given to local basins and ice patches for the purposes of referring to the areas in the field. Some of these names appear on the map. Numerous smaller isolated and geographically distinct icefields are present in the immediate region, and meteorites have been recovered from some of these during reconnaissance searches.

The icefields at the Pecora Escarpment were first searched for meteorites during a reconnaissance traverse from the Thiel Mountains, some 160 km to the west, in the 1982–1983 field season (Schutt *et al.*, 1983; Schutt, 1985). A significant meteorite concentration was discovered and 32 meteorites were collected. During the 1991–1992 season an ANSMET team systematically searched much of the most promising icefields and conducted reconnaissance searches of some of the nearby icefields (Harvey and Schutt, 1992). A total of 490 numbered meteorite specimens were recovered. Table 11 is a tabulation of the types of meteorites and their numbers from the Pecora Escarpment Icefields.

Most of the locations of the meteorites from the 1982–1983 and the 1991–1992 seasons are plotted on the Pecora Escarpment Meteorite Location Map. The area covered by the map can be seen in Fig. 38 and a reduced example of the map is given in Fig. 39. The map is plotted at a scale of 1:20,000 in a polar stereographic projection. The grid cells for this map are defined by latitude and longitude intervals of 1 minute of latitude and 10 minutes of longitude. The 1992 edition of the map was produced as a preliminary edition with the 1991–1992 season's field numbers plotted. On the 1993 edition the field numbers are replaced with the final meteorite names.

The locations of the meteorites from the 1982–1983 season were surveyed from base stations on bedrock using the snowmobile odometer or pacing for distance and a compass for relative bearings or triangulation. The locations of the 1991–1992 specimens were determined using a combination of GPS and traditional theodolite/EDM surveying methods. Most of the meteorites surveyed using GPS were determined by differential GPS techniques.

No exact location information is available for PCA 82515, PCA 82523, PCA 82524, and PCA 82527. These

four meteorites were found on one of the isolated ice areas approximately 16 km east of Lulow Rock, an area not included on the map. No location information was recorded for PCA 82521. During the 1991–1992 season an icefield about 40 km north of the Pecora Escarpment, referred to as the North Forty Icefield, was briefly visited and meteorites were found there. The three meteorites recovered there, PCA 91235, PCA 91253, and PCA 91248, are not within the map area. Another specimen, PCA 91020, was found on a small ice patch called the Halfway Icefield, which is located approximately 16 km northwest from the Pecora Escarpment. This find site is also not within the map area. The locations of these four specimens, determined using a GPS receiver, are available in the database and are indicated on Fig. 38.

A large meteorite fragment, PCA 91009, was found with many additional paired fragments scattered about in close proximity, and along a path at least 400 m downwind. Many of these fragments were mapped. The following meteorites found within the strewn field are probably paired with PCA 91009, but were not mapped: PCA 91047, PCA 91386, PCA 91432, PCA 91370, PCA 91367, PCA 91368, PCA 91361, and PCA 91360. No exact location information is available for PCA 91074, PCA 91431, and PCA 91264, but PCA 91074 is known to have been found

in the general area of PCA 91102 and PCA 91026 at the south end of the Northeast Steppes Icefield area. PCA 91431 was found within 0.5 km of PCA 91118 on the Main Icefield.

**Acknowledgments:** R. Crane, U. Krähenbühl, and L. Rancitelli were involved in the field work in the 1982–1983 field season. F. Anguita, R. Harvey, A. Krot, P. Wasilewski, and M. Zolensky were members of the 1990–1991 ANSMET field party. We appreciate their efforts in the field in acquiring meteorite location data.

?Meteorite location not on map area or not determined. See text for more information.

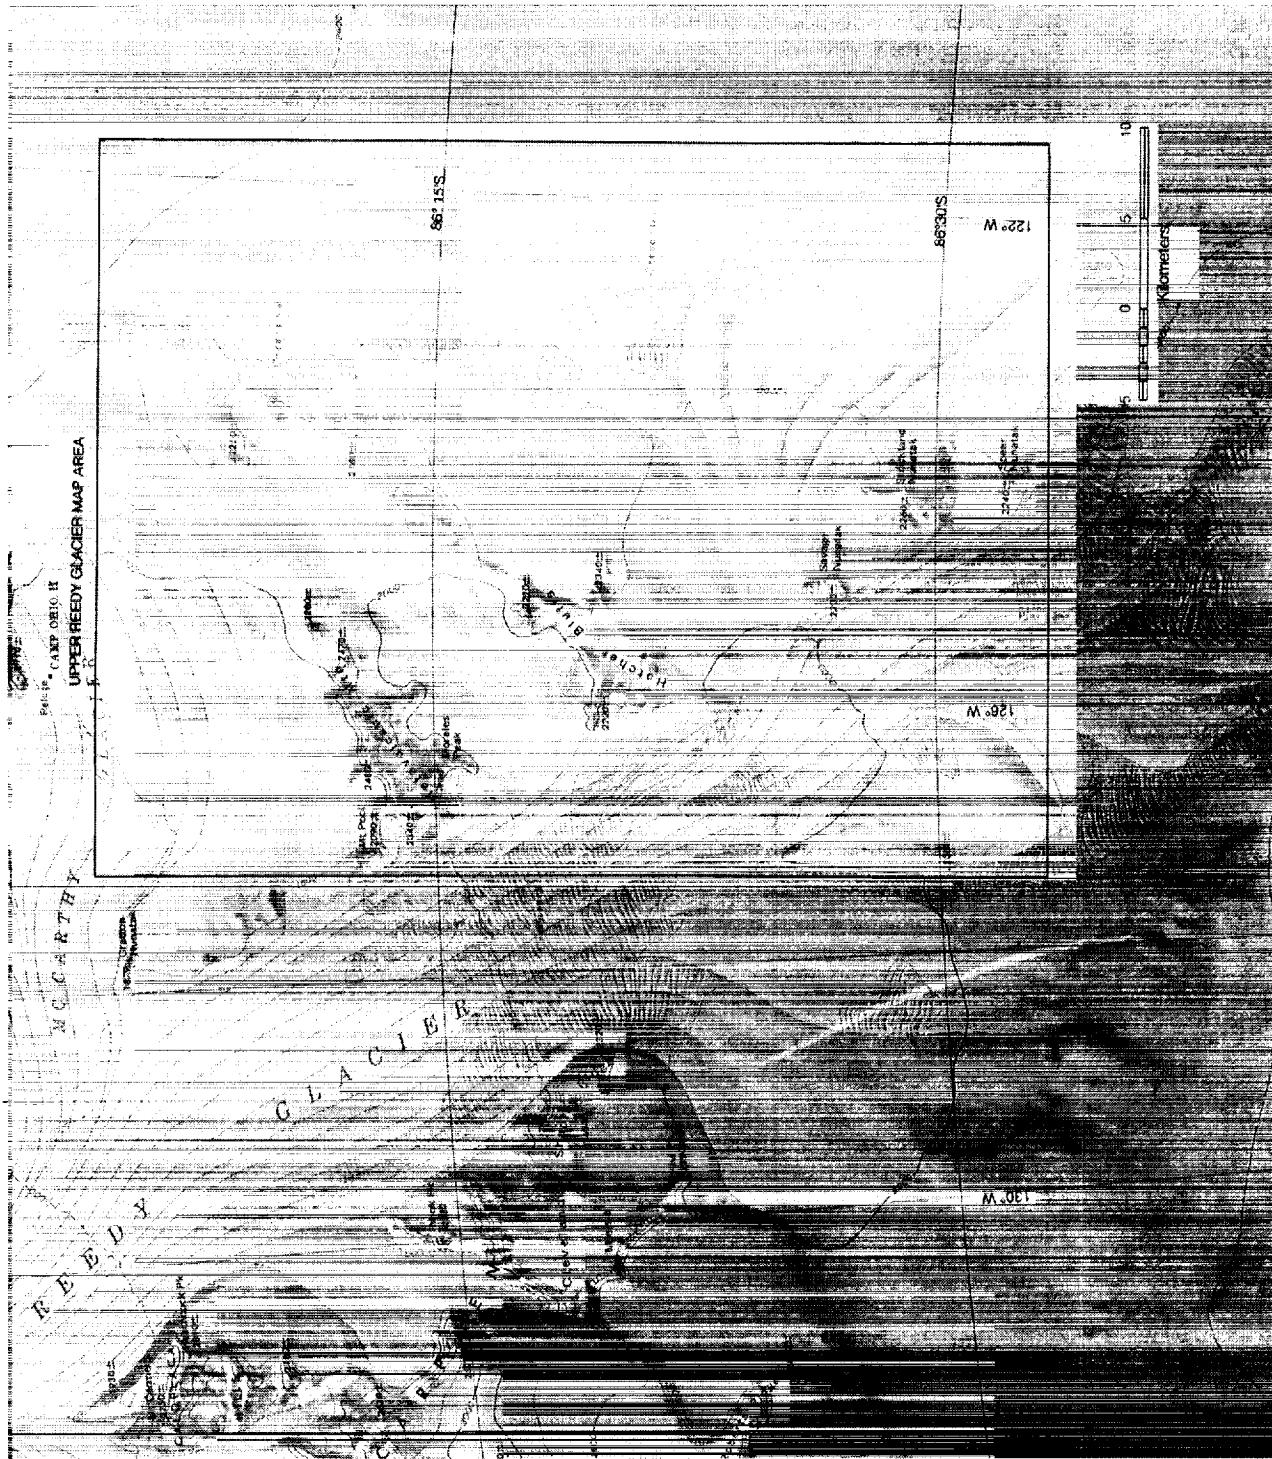

Fig. 40. Map of the Upper Reedy Glacier area of the Wisconsin Range showing the area covered by the Upper Reedy Glacier Area Meteorite Location Map. The base map is the U.S.G.S. 1:250,000-scale Calopaca Hills quadrangle.

## WISCONSIN RANGE METEORITE LOCATION MAP SERIES, UPPER REEDY GLACIER AREA

The Upper Reedy Glacier Area Meteorite Location Map covers the southernmost extent of the Wisconsin Range in the Horlick Mountains. Ice from the Polar Plateau flows through the Wisconsin Range down the Reedy Glacier, one of the larger outlet valley glaciers in the region. An ice escarpment and isolated nunataks are situated along the east side at the head of the glacier, from Spear Nunatak at the south, trending northward for 50 km. Numerous bare ice areas are present along the escarpment and adjacent to the nunataks. The area covered by the meteorite location map is shown on Fig. 40.

Four meteorite specimens were discovered in the Wisconsin Range by a Twin Otter-supported geological party visiting Spear Nunatak during the 1990–1991 season. A two-person search team returned to the area for three days during the 1991–1992 season and recovered 29 meteorites from the icefields around Spear Nunatak, Strickland Nunatak, and Point 2250. Table 12 is a tabulation of the types of meteorites and their numbers from the Wisconsin Range Icefields.

The meteorite location map is plotted at a scale of 1:50,000 in a polar stereographic projection. The grid cells for this map are defined by latitude and longitude intervals of 2.5 minutes of latitude and 30 minutes of longitude. Topographic contours and outcrop areas were digitized from the 1:250,000-scale U.S.G.S. Caloplaca Hills quadrangle and are very generalized. No icefield ice/firn boundaries are plotted on the map due to the lack of appropriate air photos or satellite images from which that information is derived. Figure 41 is a reduced example of the Wisconsin Range–Upper Reedy Glacier Area Meteorite Location Map. The locations of the 1991–1992 meteorites were determined using a single GPS receiver and averaging 25–100 fixes.

Except for the 1990 collection, the meteorite listing also

groups specimens according to the icefield area in which they were found. Exact locations of the meteorites found in 1990–1991 are not available. It is known, however, that three specimens were found in close proximity to Spear Nunatak and one was found on the East Spear Nunatak Icefield.

**Acknowledgments:** We thank S. Borg and his field party members for contributing the four 1990 meteorite specimens to the collection. We also thank P. Wasilewski for his field work in the 1991–1992 season. The support of the aircraft crew, J. C. Armstrong, C. Boutin, and H. Perk of Kenn Borek Air, Ltd., is much appreciated.

<sup>?</sup>No meteorite position was determined or location information was recorded. See text.

**Fig. 42.** Map of the Patuxent Range region showing the locations of the meteorites from the Main Icefield area, Mt. Tolchin, and Lekander Nunatak. Also shown is the area covered by the Brazitis Nunatak map (Fig. 46). The base maps are the U.S.G.S. 1:250,000-scale Thomas Hills and Pecora Escarpment quadrangles.

## PATUXENT RANGE

During the 1991–1992 field season a reconnaissance traverse was made through the Patuxent Range of the Pensacola Mountains in search of meteorite concentrations (*Harvey and Schutt, 1992*). Figure 42 is a portion of the 1:250,000-scale U.S.G.S. Thomas Hills and Pecora Escarpment quadrangles, which covers the Patuxent Range area that was investigated.

At the vast bare ice area referred to as the Patuxent Main Icefield a total of 20 specimens was recovered. Figure 43 is an aerial photo, looking southeast, which shows most of the Patuxent Range Main Icefield. All 20 meteorites from this area were found to the left (eastward) of the sinuous moraine (in the center-right of the photo) on ice that was free of terrestrial rocks. In the vicinity of the moraines the ice is littered with black rocks that induce extremely poor searching conditions. No meteorite location map has been produced for this area. Table 13 is a tabulation of types of meteorites and their numbers from the Patuxent Main Icefield. Two isolated finds, PAT 91500 and PAT 91509, were made at Lekander Nunatak (85°04'S, 064°29'W) and Mt. Tolchin (85°06'S, 065°12'W) respectively. These areas are shown in an aerial photo looking northwest (Fig. 44).

At Brazitis Nunatak (84°58'S, 067°23'W) a number of specimens were found in a small section of a larger ice patch downstream of the nunatak. Brazitis Nunatak can be seen in the distance in Fig. 44. The area was systematically searched, resulting in the recovery of 34 meteorite specimens. A scatter field of paired fragments, collected and mapped as PAT 91501,0, consisted of approximately 15 fragments strewn about 130 m downwind from the main mass, which measured 18 × 14 × 15 cm in three dimensions. Four additional fragments were found a considerable distance downwind, near the icefield edge. Table 14 is a tabulation of types of meteorites and their numbers from the Brazitis Nunatak Icefield. A map showing the relative location of the Brazitis Nunatak meteorites is shown in Fig. 45. The approximate area covered by the map is shown in Fig. 42.

The location data for the Patuxent Range meteorites are available in the AMLAMP database as latitude and longitude. The locations were determined using single GPS receivers and averaging 25–75 fixes. The stated accuracy of the fixes is ±100 m, but is probably better in practice.

**Acknowledgments:** F. Anguita, R. Harvey, A. Krot, P. Wasilewski, and M. Zolensky were members of the 1990–1991 field party. We appreciate their efforts in acquiring meteorite location data.

\*Total mass of approximately 15 fragments from a scatter field.

**Fig. 46.** Map of the Stewart Hills area indicating the location of STE 91800. The base map is the U.S.G.S. 1:250,000-scale Stewart Hills quadrangle.

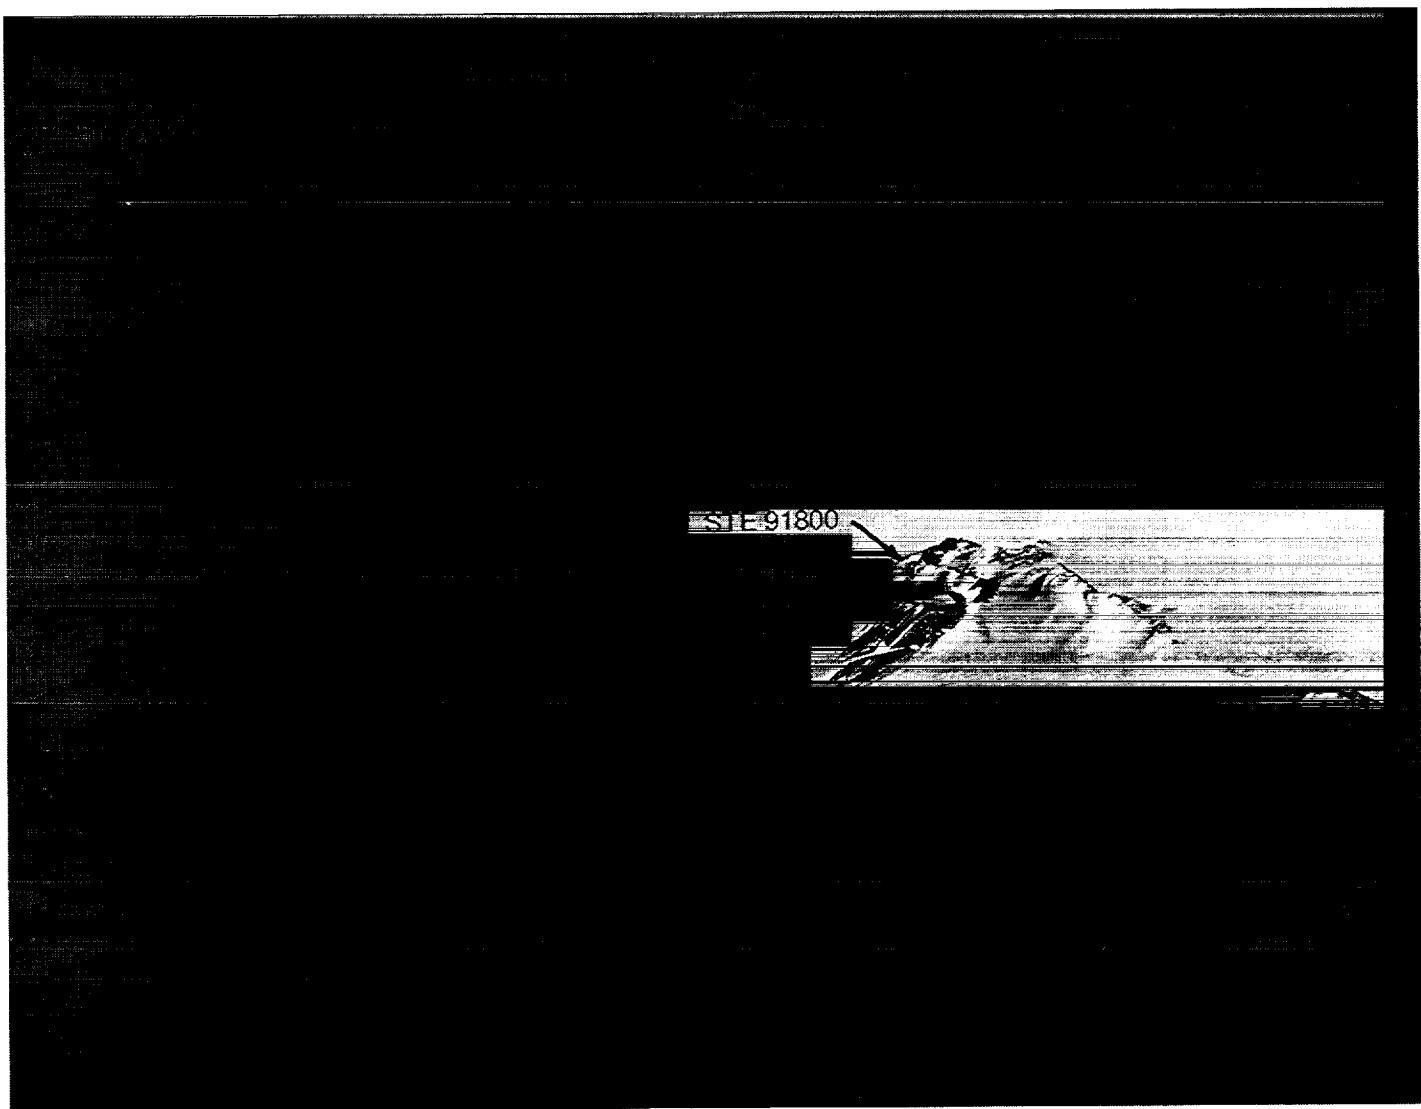

## STEWART HILLS

During the 1991–1992 field season the small icefield around Stewart Hills ( $84^{\circ}12'S$ ,  $086^{\circ}00'W$ ) was investigated during aircraft-based reconnaissance (Fig. 46). The Stewart Hills are small isolated nunataks located approximately 80 km northeast of the Thiel Mountains and are only one of two bedrock exposures on the 1:250,000-scale U.S. Geological Survey Stewart Hills quadrangle. Searches across the bare ice areas yielded no meteorites. However, one specimen, STE 91800, was discovered lying in an ice-cored moraine at the base of a talus slope at the northeast end of the nunatak. Figure 47 is an oblique aerial photo of the Stewart Hills indicating the location of this specimen.

**Acknowledgments:** We thank P. Wasilewski for his field work in the 1991–1992 season. The support of the Twin Otter aircraft crew, J. C. Armstrong, H. Perk, and C. Boutin of Kenn Borek Air, Ltd., is much appreciated.

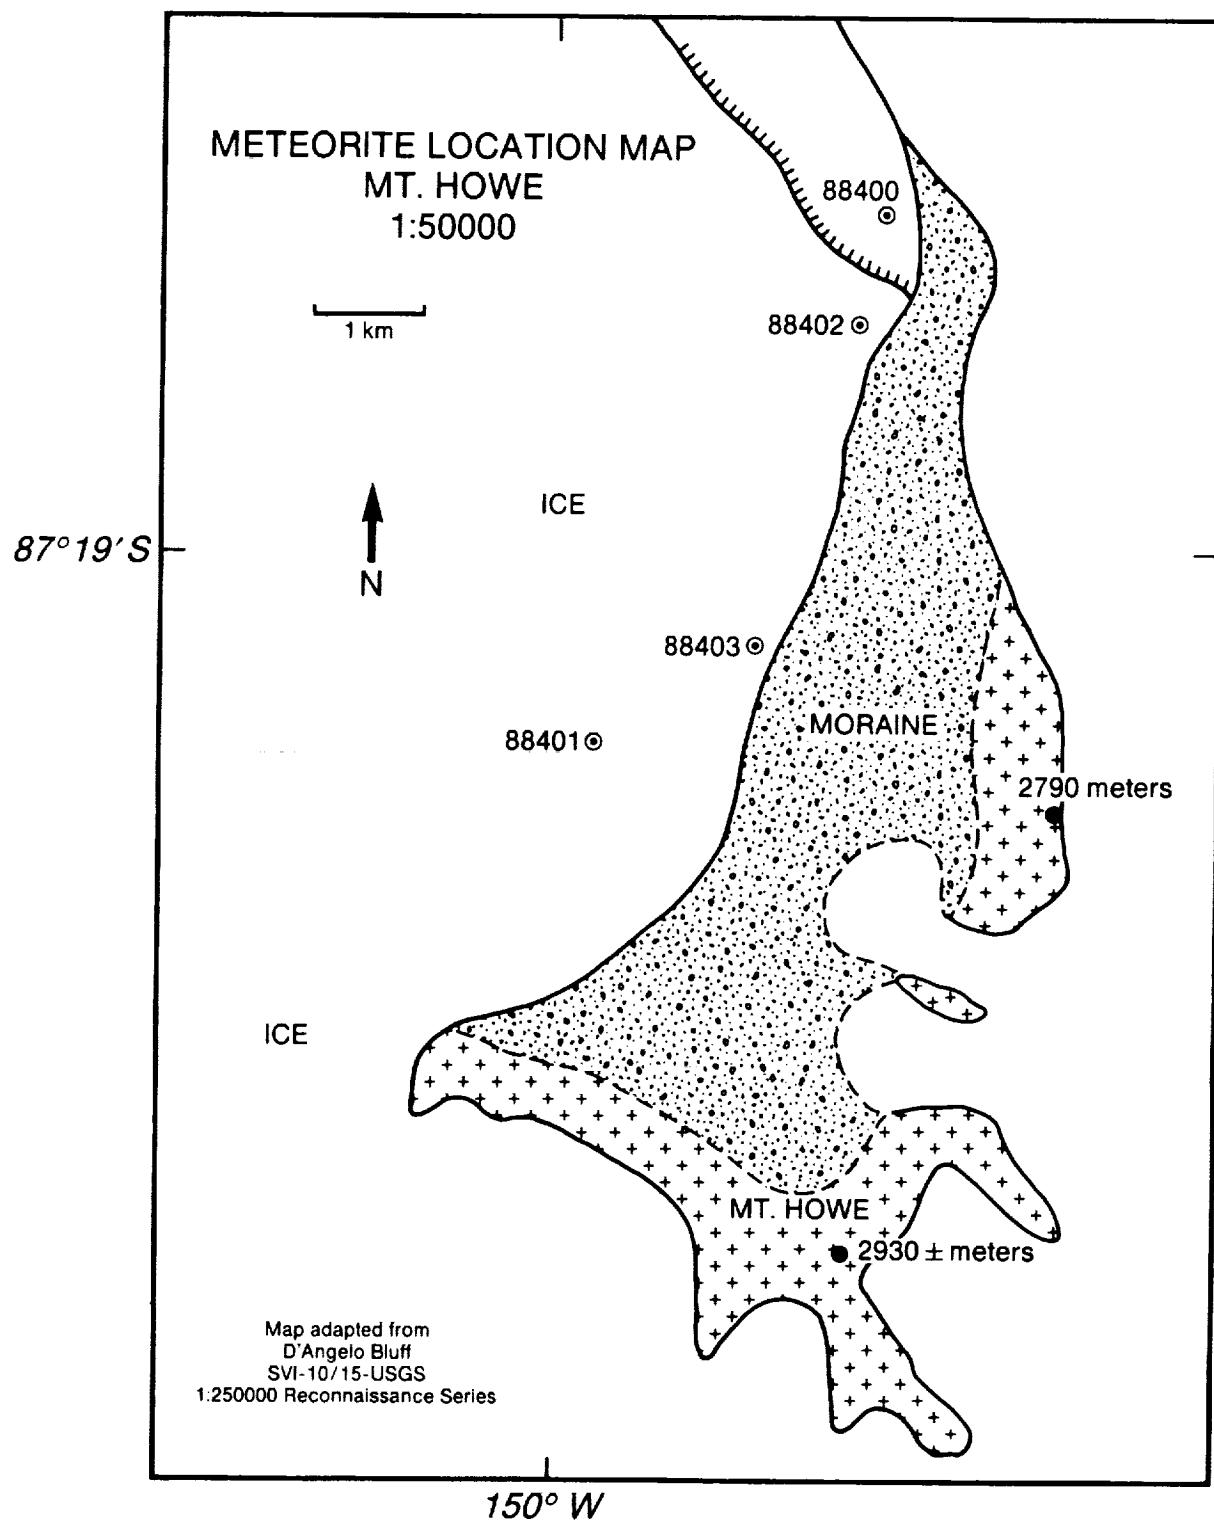

Fig. 48. Sketch map of the Mt. Howe area indicating the general locations of the four meteorites recovered during the 1988–1989 season.

## MOUNT HOWE

Mount Howe (87°22'S, 149°30' W) is located some 420 km from the South Pole, making it the southernmost exposed bedrock on the Antarctic continent. A bare ice area of approximately 30 km<sup>2</sup> is situated along the western side of the nunatak and downwind of an extensive ice-cored moraine. Flow lines and ice structures indicate that the ice is moving northward past Mount Howe down the Scott Glacier. The area is covered by the 1:250,000-scale U.S.G.S. D'Angelo Bluff quadrangle.

During the 1988-89 field season a group led by C. Swithinbank was at Mount Howe evaluating the icefield as a possible blue ice runway for large, wheeled aircraft. One of the members found HOW 88403 during the survey. A two-person ANSMET search team was sent to see if additional specimens could be found. Several days were spent in a detailed evaluation of the site. Only three additional meteorites were discovered (*Cassidy*, 1989). Figure 48 is a

sketch map of the area indicating the approximate locations of the Mount Howe meteorite specimens.

**Acknowledgments:** We thank C. Swithinbank and members of the ice runway survey group for contributing the specimen and providing logistics for the ANSMET reconnaissance team. Ralph Harvey assisted in the search for other meteorites.

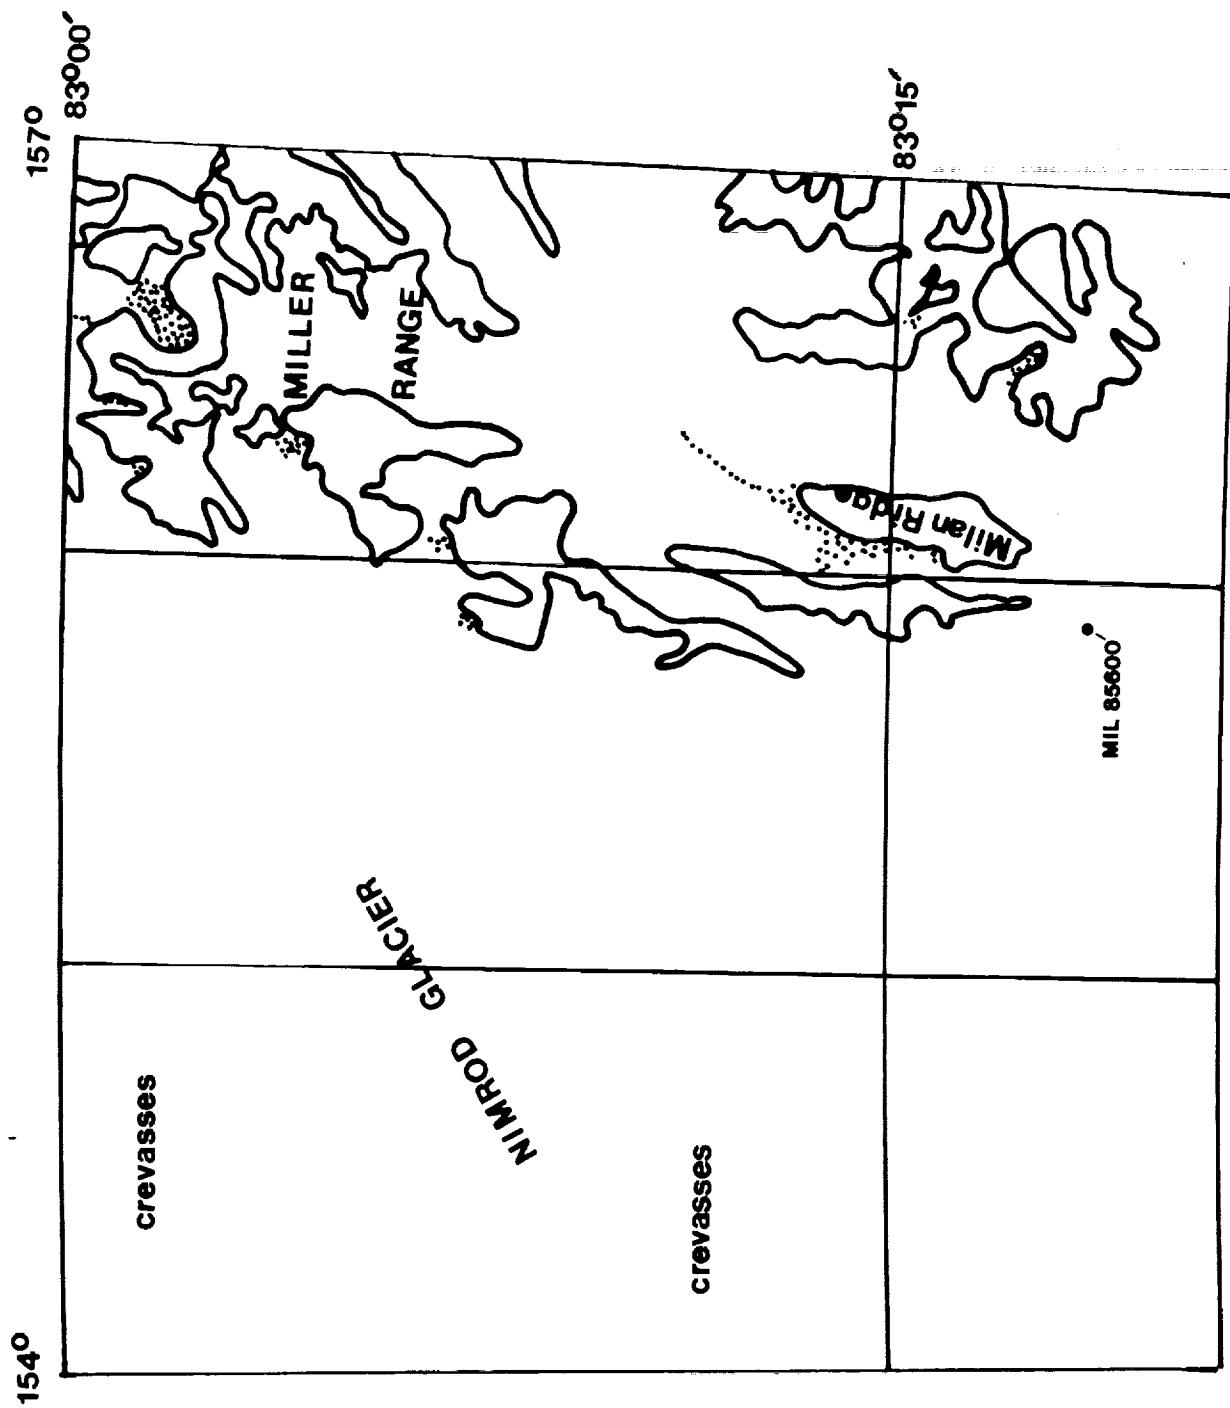

Fig. 49. Sketch map 1, showing the location of the single meteorite specimen recovered from the Miller Range, Nimrod Glacier region.

## NIMROD GLACIER REGION

During the 1985–1986 field season some of the icefields near the upper reaches of the Nimrod Glacier were investigated (Cassidy, 1986, 1992). Only a few specimens were discovered. One specimen was found south of the Miller Range ( $83^{\circ}15'S$ ,  $157^{\circ}00'E$ ) and two specimens were recovered from icefields in the southern Geologists Range ( $82^{\circ}30'S$ ,  $155^{\circ}30'E$ ). Sketch maps of these areas are shown

in Figs. 49 and 50. The 1:250,000-scale U.S.G.S. Mount Rabot quadrangle covers the Miller Range area and the Geologists Range quadrangle covers the Geologists Range area.

**Acknowledgments:** P. Englert, T. Thomas, and C. Thompson were involved in the 1985–1986 reconnaissance searches.

# User's Guide to AMLAMP Data

Data files used in the AMLAMP are now available for general use. Access to the data is through network connections to the VAX computer at the LPI. This section describes the structure and content of the various AMLAMP map plot files, explanatory text, and databases that are available on the LPI computer. Instructions for accessing and downloading these files are also included.

Meteorite location maps and thematic maps can be ordered from the LPI. An order form is provided in Appendix A.

**Accessing the AMLAMP Database.** Access to the AMLAMP database is through the NASA Science Internet computer network using telnet or FTP protocols. If you want to download the files to your computer, use the FTP. The following is a step-by-step guide to downloading files.

- From your computer enter `ftp lpi.jsc.nasa.gov` or `ftp 192.101.147.11`.
- Enter **anonymous** as the USERNAME.
- Use your e-mail address as the password.
- Change directory to AMLAMP by entering `cd amlamp`.
- Enter `get readme.1st` to retrieve the text file that has the most current information on the databases.
- To obtain the Allan Hills Main Icefield South map section, for example, go to the ANSEMT1 directory.
- Enter `cd amlamp1`. Enter `dir` to obtain a listing of the files in this subdirectory.
- Repeat the `get` command for the files you wish to retrieve.
- To go back up one subdirectory level enter `cd ..` (don't forget to use a space between the `cd` and the periods).
- Enter `quit` to exit.

**AMLAMP Data Structure.** The AMLAMP uses an arbitrary "icefield" code that has been assigned to each map area/icefield for which there are meteorite location maps. The following icefield codes are currently in use to name the various subdirectories and files from the different areas:

1. Allan Hills Main Icefield
2. Allan Hills Near Western Icefield
3. Allan Hills Middle Western Icefield
4. Allan Hills Far Western Icefield
6. Elephant Moraine—Elephant Moraine Icefield
8. Elephant Moraine—Texas Bowl Icefield
10. Elephant Moraine—Northern Ice Patch
13. Reckling Peak—Reckling Moraine Icefield
15. Lewis Cliff Area and Ice Tongue
18. Queen Alexandra Range—Goodwin Nunatak Area
20. Pecora Escarpment
25. Patuxent Range—Main Icefield Area

26. Patuxent Range—Brazitis Nunatak Icefield
30. Wisconsin Range—Upper Reedy Glacier Area
35. Thiel Mountains—Moulton Escarpment Icefield

**AMLAMP Subdirectories and Files.** A listing of the files contained in each of the subdirectories is given below. All files are in ASCII format. The size of the file in bytes, in parentheses, follows the file name.

## AMLAMP1—Allan Hills Main Icefield

- ANSMET1.TXT (52726)—Explanatory text and meteorite listing.
- ANSMET1.DB (120K)—The raw database.
- SOUTH.HPGL (223K)—The plot file for the south section of the Main Icefield Map (1993 edition).
- NORTH.HPGL (505K)—The plot file for the north section of the Main Icefield Map (1993 edition).

## AMLAMP2—Allan Hills Near Western Icefield

- ANSMET2.TXT (17593)—Explanatory text and meteorite listing.
- ANSMET2.DB (36K)—The raw database.
- NEAR.HPGL (206K)—The plot file for the Near Western Icefield Map (1991 edition).

## AMLAMP3—Allan Hills Middle Western Icefield

- ANSMET3.TXT (9021)—Explanatory text and meteorite listing supplement.
- ANSMET3.DB (18K)—The raw database.
- MIDDLE.HPGL (156K)—The plot file for the Middle Western Icefield Map (1987 edition).

## AMLAMP4—Allan Hills Far Western Icefield

- ANSMET4.TXT (30453)—The explanatory text and meteorite listing.
- ANSMET4.DB (69K)—The raw database.
- EAST.HPGL (251K)—The plot file for the Far Western Icefield Map East section (1987 edition).
- WEST.HPGL (165K)—The plot file for the Far Western Icefield Map West section (1991 edition).

## AMLAMP6—Elephant Moraine—Elephant Moraine Icefield

- ANSMET6.TXT (24696)—The explanatory text and meteorite listing.
- ANSMET6.DB (54K)—The raw database.
- ELEPHANT.HPGL (329K)—The plot file for the Elephant Moraine Icefield Map (1991 edition).

**AMLAMP8—Elephant Moraine—Texas Bowl Icefield**

- ANSMET8.TXT (101405)—The explanatory text and meteorite listing.
- ANSMET8.DB (234K)—The raw database.
- TEXAS.HPGL (951K)—The plot file for the Texas Bowl Icefield Map (1991 edition).

**AMLAMP10—Elephant Moraine—Northern Ice Patch**

- ANSMET10.TXT—Explanatory text and meteorite listing.
- ANSMET10.DB—The raw database.
- NICE.HPGL—The HPGL plot file for the Northern Ice Patch meteorite location map (1993 preliminary edition; field numbers only for the 1992 collection).

**AMLAMP13—Reckling Peak—Reckling Moraine Icefield**

- ANMSET13.TXT—Explanatory text and meteorite listing.
- ANSMET13.DB—The raw database.
- RECKLING.HPGL—The HPGL plot file for the Reckling Moraine Icefield (preliminary 1993 edition; field numbers only for the 1992 collection).

**AMLAMP15—Lewis Cliff Area**

- ANSMET15.TXT (146105)—The explanatory text and meteorite listing.
- ANSMET15.DB (339K)—The raw database.
- AREA.HPGL (504K)—The plot file for the Lewis Cliff Area Map.
- NORTH.HPGL (881K)—The plot file for the Lewis Cliff Ice Tongue North Section Map (1991 edition).
- SOUTH.HPGL (602K)—The plot file for the Lewis Cliff Ice Tongue South Section Map (1991 edition).

**AMLAMP18—Queen Alexandra—Goodwin Nunataks Area**

- ANSMET18.TXT (11199)—The explanatory text and meteorite listing.
- ANSMET18.DB (18K)—The raw database.
- QUEEN.HPGL (237K)—The plot file for the Queen Alexandra—Goodwin Nunataks Area Map (1992 edition).

**AMLAMP20—Pecora Escarpment**

- ANSMET20.TXT (47949)—The Pecora Escarpment explanatory text and meteorite listing.
- ANSMET20.DB (103K)—The raw database.
- PECORA.HPGL (849K)—The plot file for the Pecora Escarpment Map (1993 edition).

**AMLAMP25—Patuxent Range—Main Icefield**

- ANSMET25.TXT (2067)—The explanatory text and meteorite listing.
- ANSMET25.DB (5K)—The raw database.

**AMLAMP26—Patuxent Range—Brazitis Nunatak Icefield Subdirectory**

- ANSMET26.TXT (2108)—The explanatory text and meteorite listing.
- ANSMET26.DB (7K)—The raw database.

**AMLAMP30—Wisconsin Range—Upper Reedy Glacier Area**

- ANSMET30.TXT (5277)—The explanatory text and meteorite listing.
- ANSMET30.DB (9K)—The raw database.
- WISCONSIN.HPGL (246K)—The plot file for the Wisconsin Range—Upper Reedy Glacier Area Map (1992 edition).

**AMLAMP35—Thiel Mountains—Moulton Escarpment**

- ANSMET35.TXT (5899)—The explanatory text and meteorite listing.
- ANSMET35.DB (8K)—The raw database.
- THIEL.HPGL (357K)—The plot file for the Moulton Escarpment Map (1992 edition).

**AMLAMP File Types**

**\*.TXT FILES**—ASCII (text with line breaks) files have TXT extension.

**\*.DB FILES**—These files are the raw database, which are in ASCII format. These data can be easily ported to databases or spreadsheets because the files are space-delimited. The format of an AMLAMP database file is

<u>Column</u>	<u>Description</u>
1–20	Name
21	space
22–23	Icefield code
24	space
25–54	Classification
55	space
56–61	Antarctic Meteorite Newsletter reference (Vol. (No.))
62	space
63–72	Meteorite weight in grams
73	space
74–83	Reserved for future AMLAMP use
84	space
85–94†	Meteorite/station UTM grid northing (meters)
95	space
96–105†	Meteorite/station UTM grid easting (meters)
106	space
107–112	Grid cell address
113	space
114–125	Meteorite/station latitude (ddmmss.ssss)
126	space
127–139	Meteorite/station longitude (ddmmss.ssss)
140	space
141–152	Meteorite/station name latitude (ddmmss.ssss)

153	space
154-166	Meteorite/station name longitude (ddmmss.ssss)
167	space
168-179	Meteorite/station tie-point latitude (ddmmss.ssss)
180	space
181-193	Meteorite/station tie-point longitude (ddmmss.ssss)

†UTM grid coordinates currently are only available for the Allan Hills Icefields and Elephant Moraine Icefields.

\*.HPGL FILES—\*.HPGL files are plotter files and are in Hewlett-Packard Graphics Language (HPGL) format. HPGL is a widely used format developed for outputting vector graphics to plotters. If you have an E-size HP or HP-compatible plotter you can produce maps directly from these files.

A large number of commercial and shareware software programs are capable of importing and manipulating HPGL files. Other CAD and graphics programs that are available could be used if the HPGL files were converted into their native formats or formats they are capable of using. Most of these programs are PC-based. However, several of the commercial programs also have Macintosh equivalents. The following is a listing of some of these programs. This list is by no means complete and comprehensive, nor have most of these programs been tested with AMLAMP files. No recommendation or endorsement of any hardware or software product is implied.

#### Desktop Publishing

- *PageMaker 5.0* (PC), Aldus Corp.
- *FrameMaker* (PC), Frame Technology
- *QuarkXPress* (PC), Quark Inc.

#### Word Processing

- *Word for Windows* (PC and Mac), Microsoft Corp. Can import HPGL files into a document. File size limitations at present. No pan and zoom.

#### Viewers/Conversion Programs

- *Outside In for Windows 2.0* (PC), Systems Compatibility Corp. Allows HPGL files to be viewed. Pan and zoom is available. No direct conversion, but screen capture to file is possible. File size limitations.

- *SHOWHPGL v1.9* (PC), Shareware. Views HPGL files on screen. No pan and zoom feature.
- *HiJack for Windows and DOS* (PC), Inset Systems. HPGL file conversion to a wide variety of graphics formats. Also allows viewing of files in Windows version.
- *PrintGL v. 1.18* (PC), Shareware. Plotter emulation software. Displays, prints HPGL files, and converts to .PCX and .IMG graphics file formats.
- *CADMover* (Mac). Converts HPGL to other formats used by a number of Mac-based drafting programs.
- *PowerDraw Translator* (Mac). Converts HPGL to other formats used by a number of Mac-based drafting programs.
- *Myriad 2.0* (PC), Information Graphics. Converts HPGL files to other graphics formats. Also has pan and zoom ability.
- *DoDOT 4.0* (PC), Halcyon Software. Converts HPGL files to other graphics formats. Also has pan and zoom ability.
- *FreezeFrame* (PC), DeltaPoint, Inc. Converts HPGL files to other graphics formats. Also has pan and zoom ability.
- *Panoramic* (PC), Cimmetry Systems, Inc. Converts HPGL files to other graphics formats. Also has pan and zoom ability.

#### Graphics/CAD

- *Freelance Graphics 2.0* (PC), Lotus Corp.
- *Hollywood 1.0V2* (PC), Claris Corp.
- *Persuasion 2.1 for Windows* (PC), Aldus Corp.
- *PowerPoint 3.0* (PC), Microsoft Corp.
- *Stanford Graphics 2.1* (PC), 3-D Visions Corp.
- *TurboCAD Pro for Windows* (PC), International Microcomputer Software, Inc. Imports HPGL files into the CAD environment.
- *Freehand* (PC ver. only), Aldus Corp. View and edit capabilities.
- *Intellidraw* (PC ver. only), Aldus Corp. View only.
- *Drafix CAD 2.1a* (PC), Foresight Resources Corp. Imports into CAD environment.

HP plotters, of course, are capable of plotting HPGL files. There are also a considerable number of laser and ink-jet printers that also emulate HPGL directly without converting to some other format.
