WASHINGTON

NACA WARTIME REPORTS are reprints of papers originally issued to provide rapid distribution of advance research results to an authorized group requiring them for the war effort. They were previously held under a security status but are now unclassified. Some of these reports were not technically edited. All have been reproduced without change in order to expedite general distribution.

FLIGHT MEASUREMENTS OF THE ELEVATOR DEFLECTIONS

USED IN LANDINGS OF SEVERAL AIRPLANES

By Joseph R. Vensel

SUMMARY

A collection of data on the elevator deflections used in landings of several airplanes is presented in tabular form. The physical characteristics of these airplanes are also given. The elevator deflection used in landing some airplanes was found to be as much as 14.4° greater than that used to stall under the same flight and loading conditions.

INTRODUCTION

The purpose of this report is to present flight-test data on the elevator deflections used in landing for a number of airplanes. Such information is not available in published form at the present time.

The elevator deflection required to land an airplane is of interest to designers, since the up-elevator deflection range is likely to be determined by the landing condition. Further, if it should be desired to decrease the elevator hinge moments by use of narrow-chord elevators, due consideration must be given the elevator deflection needed for landing. The problem is also of interest when an attempt is made to limit the up-elevator travel of an airplane so that it cannot be stalled in flight but will still be capable of making a good landing.

Wind-tunnel investigations made on the effect of ground interference on trim (references 1 and 2) indicate that when flaps are used large increases in up-elevator deflections may be required near the ground as compared to those at altitude in order to attain a given high angle of attack. These observations are verified in the data contained in this report.

The limited nature of the data available did not permit a complete investigation of ground interference on trim. It is fully appreciated that the value of \mathbf{C}_{L} for

stall at altitude and at landing is probably not the same. However, the comparison of the elevator deflections between stalls at altitude and landings under the same loading conditions is made. The designer should be able to determine from tunnel tests or calculations the elevator deflection required to stall at altitude.

APPARATUS AND TESTS

The data were collected from photographic records taken in tests of the stalling characteristics and landings of the airplanes where the stalls and landings were made under comparable conditions. The records were obtained by installations of NACA recording instruments and a synchronized phototheodolite. The elevator deflections used in landing were determined by correlating the elevator control-position record with the normal acceleration record which shows a marked change at ground contact. Elevator deflections for landings were taken from the record an instant before contact.

Physical characteristics of the airplanes for which data were available are given in table I, and line drawings showing their general arrangement are shown in figure 1.

RESULTS AND DISCUSSION

Table II contains the data for simplanes 1 through 9. This table includes the flap setting, the elevator deflection just before ground contact, the vertical velocity just before contact, the normal acceleration an instant before contact, the maximum normal acceleration at contact, the attitude of the thrust axis at contact, the elevator deflection required to produce an unaccelerated stall at altitude, the indicated air speed to stall at altitude, and the pilot's remarks on the landing.

A summary of the material in table II is given in table III, where the average elevator deflection to make a three-point landing, the elevator angle to stall at altitude, and the difference between the elevator deflection for these conditions are shown. Pertinent data on a number of airplanes not included in table II are also given in table III.

It will be noted from table III that usually, when flaps are used, the difference between the average elevator deflection to make a three-point landing and the elevator deflection to stall at altitude ($\Delta \delta_e$) is quite large; for airplane 2, with 50° flap deflection, $\Delta \delta_e$ is 14.4° .

An attempt was made to correlate the data by reducing $\Delta\delta_e$ to an equivalent change in angle of attack of the horizontal tail surface, but due to the large number of indeterminate factors involved, no consistent results for all the airplanes could be obtained.

An important element that contributes to the magnitude of $\Delta \delta_e$ is the piloting technique employed in the execution of a landing. For example, if a landing approach is made just above the stalling speed in a heavily flapped airplane, it may be impossible to pitch to a three-point attitude and reduce the vertical velocity to zero even by the use of full up elevator, whereas, if the pilot keeps an appreciable margin of speed above stalling, it usually is found that the same airplane can be landed in a threepoint attitude with no difficulty. Or, if the airplane is stalled a few feet above the ground, full up elevator is of no avail in attempting to produce a good landing; whereas, if the same airplane is stalled almost in contact with the ground, the elevator travel may be quite sufficient for a good landing. Landing in gusty air conditions also may demand large up-elevator deflections.

Until a more comprehensive investigation of ground effect on trim is made, it is hoped that the data contained herein will be helpful in the design of new airplanes.

CONCLUSIONS

The elevator deflections used in landings of some airplanes are considerably larger than the elevator deflection required to stall at altitude. The maximum value of this difference in the elevator angle required to stall at altitude and to make a three-point landing of the airplanes investigated was 14.4° under the same flight and loading conditions.
