#### THE AERODYNAMICS OF A WIND-TUNNEL FAN

By Blake W. Corson, Jr.

### SUMMARY

The vortex %lade-element theory modified to apply to an axial fan working in a duct is reviewed, Thrust and power coefficients for a fan are identified with the corresponding coefficients for airplane propellers. Tho relation of prossuro producod by the fan to the blade-element coefficients Is developed. The distribution of axial velocity of fluid through a fan Is assumed to he controlled by the fan itself. The radial distribution of tangential velocity imported by tho fan to fluid moving through the fan is shown to be indopendent of the axial-velocity distribution.

\*,

A nondimensional coefficient, designated the rotation constant, is introduced. This constant is based solely upon design information. The use of the rotation constant in simplifying the design of a fan for a specific operating condition is demonstrated. Based on the use of the rotation constant. a graphical method is outlined by which the performance of *a* given fan in a given wind tunnel may be predicted and by which the distributions of axial velocity of the fluid through the fan under various oporating conditions may bo established.

:.,

# . The contract of the contrac INTRODUCTION .,

Comprehensive treatment of factors bearing on the operation of axial fans have been made by several investigators. Following customary procedure, each investigator assumed that the axial velocity of fluid through the fan<br>was uniform. Ignoring viscous distortion of the velocity Ignoring viscous distortion of the velocity distribution, this assumption is logical for the design condition but may not, of necessity, hold for all operating conditions. Radially nonuniform axial velccity under some operating conditions. is mentioned in roforonce 1, Porformanco estimation for a fan that must work over a

range of operating conditions can be made only by some procedure which takes account of the interrelation of axial velocity and torque distributions.

This paper deals only with the aerodynamics of the fan proper and demonstrates the manner in which the radial distribution of axial velocity of fluid through a fan is governed by the geometry of the fan itself. Although special reference is made to a wind-tunnel fan, the conclusions arrived at here apply to any single-stage fan working in a close duct. Some of the derivations published in the references are repeated here, but a consistent notation is used to coordinate the work of various authors. The vortex blade-element theory modified to apply to a fan working in a duct is doveloped. A direct procedure is indicated for design of the optimum fan for a given combination of mass flow, shaft speed, power, and fan diameter. A relation is established between elemental torque coefficiont. axial velocity. radius. and a rotation constant. Based on this relation, a mothod is given by which performance charts for a fan may bo prepared.

#### BLADE-ELEMENT THEORY

A vector diagram of forces and velocities acting on a blade element is shown in figure 1. The element is a section of a fan blade at radius r and is of area b X dr. The rotational interference velocity, designated a'  $(2\pi r n)$ in reference 2, is assumed in this derivation to be  $\pi/2$ , one-half of the final rotational velocity imparted to the annulus of air by B blade elements at radius r, This assumption is used in references 1 and  $3.$  The inflow  $ve$ locity, av in reference 2, for a fan working in a duct is assumed to be zero. The torque, power, and thrust characteristics derived here are expressed as coefficients identical with the propoller characteristics defined in roforonco 2.

$$

$$
\n(1)

In a later analysis the axial velocity will be considered nonuniform. Since over-all thrust and torque are obtained by integration along the radius of the elemental thrusts and torques, velocity varying with radius must remain under the integral sign. It is better, therefore, to use coofficients that include the axial velocity.

$$

.

.

,

In appendix A the factor  $\left(1 - \frac{w/2}{2\pi rn}\right)$  is shown to represent the rotational efficiency of the blade element. The ratio  $tan \frac{\phi}{\phi + \gamma}$ *represents* the profile efficiency and is the expression arrived at by simple blade-element theory.

# PRESSURE RELATION

Consider a fan unit working in a closely fitting cylindrical duct and moving's nonviscous incompressible fluid. Limit the length of the cylindrical portion of the duct to a short distance on each sido of the fan and lot the duct torminato in infinitely largo conos oxpanding upstream and downstream. In order to avoid having to deal with rotation of the fluid, regard tho fan as an actuator disk. Tho *as*sumption of incomprossiblo flow d.omands that thoro be no discontinuity of axial velocity at the fan. Useful energy imparted to the flow by the fan, therefore, must appear as increase in static pressure.

At a distance upstream where the velocity of flow is negligibly small, pressure energy in the fluid is entirely static pressure and is equal to the total pressure. Inasmuch as there can be no pressure gradient in **~otionl~ss** flow (if gravity is ignored) the total pressure is constant for all streamlines. By Bernoulli's theorem the total pressure is constant along any one streamline; hence, the total pressure is constant throughout the flow at all points upstream from the fan. The same reasoning can be applied to show that the total pressure is constant throughout the flow downstream from the fan. It then follows that the increment in total pressure across the fan must be constant over the entire fan disk and must appear only as an increase in static pressure.

The fact that the static-pressure increment across the fan is constant over the disk places **no** restrictions on the distribution of static pressure and axial velocity, which is governed by the relativo amounts of work being dono by various regions of the fan. If the tip portion of the fan is working harder than the portion near the hub.

### NACA Technical Note No. 820 9

an axial velocity greater than the mean is induced through the region of the tip and is accompanied by correspondingly lower static pressure in that region on both sides of' the propeller disk. The portion near the hub, doing relatively less work, cannot maintain an axial velocity as groat as the moan; consequently, highor static prossuros on both sides of the propoller disk exist in this region. Tho static-pressure incromont across tho fan, however, is everywhere tho same and the axial velocity through any region is directly proportional to the relativo amount of ~ork being done by that portion of the fan.

In the design of a fan, the distribution of axial velocity must be assmned and is often regarded as uniform-If diameter and shaft speed are known, the optimum fan can be designed for the given value of  $J_{\bullet}$  Whenever the fan is required to work at a value of J other than the design value, some portion of tho fan is forcod to do relatively more work than another and a nonuniform axialvelocity distribution results. Aerodynamic characteristics of the fan, therefore, cannot be predicted by the assumption of a uniform axial-velocity distribution under all operating conditions.

.

 $\bullet$ 

I

 $\ddot{\phantom{1}}$ 

.

The conclusion that a constant static-pressure increment exists over the entire propeller disk was based on the assumption that no rotation was imparted to the fluid as it passed through the fan. Consider a single fan, without countervanes. If the fact is acknowledged that the torque driving the fan reacts only on the fluid and that the fan does impart rotation to the fluid, then account must bo taken of variation in tho static-prossuro increment across the fan disk, due to centrifugal pressure. The axial velocity of a fluid particle (in incompressible flow) is not changed during passage of the particle through the fan. The absolute velocity of the fluid particle, however, is increased because of tho rotational velocity imparted to it by the fan. Inseparable from this retation is an accompanying centrifugal pressure dovnistream from the fan, which is manifest as static pressure. The cenrifugal pressure increases radially from hub housing to duct wall and at any radius is equal to the integrated centrifugal pressure increments from the hub housing to that radius. It is now apparent that the fan imparts energy to the fluid as an increase both in static pressure and in absoluto dynamic pressure and that tho staticprossuro increment being partly centrifugal cannot be constant over tho ontiro fan, Investigation of tho distri-

bution of these pressure increments over the fan disk is now in order. The flow pattern being assumed symmetrical about the fan axis, investigation may be confined to a plane through the axis in the region between the hub housing and duct wall. (Soc fig. 2.)  $W = \frac{1}{2}$  $\mathcal{L}(\mathcal{L})$  and  $\mathcal{L}(\mathcal{L})$ 

The only radial variation of the static-pressure in-' crement through the fan is the variation of the centrifugal pressure; hence the static-pressure gradient is the centrifugal-pressure gradient, which is

$$
\frac{dp}{dr} = \rho \omega^2 r
$$
  
dp =  $\rho \omega^2 r dr$  (9)

The blade-element theory, equation (5), shows the pressure at radius r to be the series of the series of

$$
p = \frac{d T}{2\pi r dr} = \frac{\rho V^2 D^2 B T_c' d(\frac{r}{D})}{2\pi D^2 \frac{r}{D} d(\frac{r}{D})}
$$

$$
p = \frac{\rho V^2 B T_c'}{2\pi \frac{r}{D}}
$$

If equations (1) and (4) are combined and K is eliminated. expressions for  $T_{\alpha}$ <sup>t</sup> and p can be obtained

$$
T_c' = \frac{Q_c'}{\frac{r}{D} \tan (\phi + \gamma)}
$$
  

$$
p = \frac{R V^2 B Q_c'}{2\pi (\frac{r}{D})^2 \tan (\phi + \gamma)}
$$
 (10)

Inasmuch as the gradient of pressure increment is given as a function of the angular velocity imparted to the fluid by the fan, it would be useful to know the pressure increment in terms of the same parameter. The torque

 $\mathcal{L}^{\mathcal{A}}(\mathcal{A})$  and  $\mathcal{L}^{\mathcal{A}}(\mathcal{A})$  and  $\mathcal{L}^{\mathcal{A}}(\mathcal{A})$  and  $\mathcal{L}^{\mathcal{A}}(\mathcal{A})$ 

 $\mathcal{L}^{(1)}$  and  $\mathcal{L}^{(2)}$ 

requtred to impart. angular velocity w to an annulus of fluid at radius r is given by

$$
dQ = 2\pi r dr
$$
  $\rho V r \omega r = 2\pi \rho D^3 \left(\frac{r}{D}\right)^2$   $V \omega r d \left(\frac{r}{D}\right)$ 

By blade-element theory,

.

 $\cdot$ 

.

$$
dQ = \rho V^{2} D^{3} B Q_{c} \cdot d \left(\frac{r}{D}\right)
$$
\n
$$
\rho V^{2} D^{3} B Q_{c} \cdot d \left(\frac{r}{D}\right) = 2\pi \rho D^{3} \left(\frac{r}{D}\right)^{2} \text{ Vwr } d \left(\frac{r}{D}\right)
$$
\n
$$
Q_{c} \cdot V B = 2\pi \left(\frac{r}{D}\right)^{2} \text{ Ur}
$$
\n
$$
wr = \frac{Q_{c} \cdot V B}{2\pi \left(\frac{r}{D}\right)^{2}} = w
$$
\n(11)

If the values in equation (11) are substituted in equation (10), the pressure increment is expressed as a function of angular velocity and radius.

$$
p = \frac{\rho \nu \omega r}{\tan (\phi + \gamma)}
$$
  

$$
p = \frac{\rho \omega r}{\tan (\phi + \gamma)}
$$
  

$$
\frac{\rho \omega r}{\tan (\phi + \gamma)}
$$
  

$$
\frac{\nu}{2\pi r n} = \frac{\pi}{2}
$$
  

$$
\frac{\omega r}{\tan (\phi + \gamma)}
$$
  

$$
p = \rho \omega r^{2} (\rho \pi n - \frac{\omega r}{2}) \frac{\tan \phi}{\tan (\phi + \gamma)}
$$
  

$$
p = \rho \omega r^{2} (\rho \pi n - \frac{\omega}{2}) \eta_{0}!
$$
  

$$
\frac{\pi}{2} \frac{\pi}{\tan (\phi + \gamma)}
$$

It is not feasible to express the profile efficiency qs a function of either of the independent variables in equation (12). The profile efficiency may be assumed to be unity (that is,  $\gamma = 0^0$ ) without introducing much error In order to determine the extent of its influence, however profile efficiency will be retained and regarded as a constant.

 $12$ 

the control of the control of the control of

**Service** 

The differential of pressure increment, from equation  $(12)$ , is and the same

 $\ddot{\phantom{a}}$ 

 $\overline{\mathcal{O}}_2$ 

$$
dp = \eta_0! \rho \left[ \omega r^2 \left( -\frac{dw}{2} \right) + \left( 2\pi n - \frac{w}{2} \right) \left( 2\omega r dr + r^2 dw \right) \right]
$$

$$
dp = \eta_0 \cdot \rho \left( \frac{r^2 \omega d\omega}{2} + 4\pi n \omega r dr + 2\pi n r^2 d\omega - \omega^2 r dr - \frac{\omega r^2 d\omega}{2} \right)
$$
  

$$
dp = \eta_0 \cdot \rho r \left( -r \omega d\omega + 4\pi n \omega dr + 2\pi n r d\omega - \omega^2 dr \right) \qquad (13)
$$

If<sup></sup> dp is eliminated between equations (9) and (13).

$$
\omega^2 \text{ d}r = \eta_0^{-1} \left(-\text{ wrdw} + 4\pi n \omega \text{d}r + 2\pi n r \text{d}\omega - \omega^2 \text{ d}r\right) \qquad (14)
$$

The steps followed in solving equation (14) are given in appendix B; the solution is stated in the following equation:

$$
r^{2} \frac{w}{2\pi n} = 0 \left( \frac{2\eta_{0}}{1 + \eta_{0}} - \frac{w}{2\pi n} \right)^{\frac{1 - \eta_{0}}{1 + \eta_{0}}}
$$
(15)

Observation will show that, for reasonable values of w.

n, and  $\eta_0$ , the function  $\left(\frac{2\eta_0}{1+\eta_0} - \frac{\omega}{2\pi n}\right)^{1+\eta_0}$  is always<br>nearly equal to  $\frac{1-\eta_0}{1+\eta_0}$ 

nearly equal to unity. The error introduced by assuming perfect profile efficiency is much less than  $1 - \eta_{0}$ . The simplifying assumption that  $\gamma = 0^{\circ}$  made in references l and 3 is found justifiable for equation (15) and will be

used here; therefore  $r^2 \frac{w}{2\pi n}$  is a constant. The expression  $2\pi n$  is a constant for all radii.

$$
\mathbf{r}^{2} \mathbf{w} = -\mathbf{0}_{1}
$$
\n
$$
\mathbf{w} = \frac{\mathbf{0}_{2}}{\mathbf{r}/D} = -\frac{\mathbf{0}_{3}}{\mathbf{r}/D} = -\frac{\mathbf{0}_{4}}{\mathbf{r}/D} = -\frac{\mathbf{0}_{5}}{\mathbf{r}/D} = -\frac{\mathbf{0}_{6}}{\mathbf{r}/D} = -\frac{\mathbf{0}_{7}}{\mathbf{r}/D} = -\frac{\mathbf{0}_{8}}{\mathbf{r}/D} = -\frac{\mathbf{0}_{9}}{\mathbf{r}/D} = -\frac{\mathbf{0}_{1}}{\mathbf{r}/D} = -
$$

ţ

#### NACA Technical Note No. 820 13

Equation (17) shows that, as the fluid travels downstream from the fan, its tangential velocity is Inversely proportional to the radius, This expression was derived by considering the interrelation of thrust, torque, tangential velocity, and pressure. Although, individually, these quantities are 'functions of the axial velocity of the fluid at the radius of the blade element, the final expression is indopendent of axial velocity. Equation (17) will be considered to hold for any radial distribution of axial velocity.

A useful relation between elemental torque coefficient and radius can be obtained by combining equations (11) and *(17).*

$$
\frac{Q_{\text{C}} \cdot \text{V} \cdot B}{2\pi \left(\frac{\text{r}}{D}\right)^2} = \text{w} = \frac{Q_{\text{S}}}{\text{r}/D}
$$

$$
Q_{\rm c} \cdot V = \frac{2\pi G_{\rm B}}{B} \frac{r}{D}
$$

Multiplying through by  $\frac{1}{2}$  gives (nD) <sup>-</sup>

.

.

. .

.,

 $Q_c$ <sup>*t*</sup>  $\left(\frac{\gamma}{nD}\right)^2 = \frac{2\pi C_8}{B n D} \frac{r}{D} \frac{\gamma}{nD}$ (18)

From equation  $(17)$  it can be seen that the dimensions of the constant  $C_{2}$  are in feet per second. The constant **2πC<sub>2</sub>** is therefore nondimensional. The rotation constan H defined as  $\tau = \frac{2\pi G_a}{\pi G}$  holds for overy operating section  $\sigma \vec{f}$ 

the propeller at a given instant. Since  $V/nD$  for a blade element is  $J^{\dagger}$ , equation (18) becomes

$$
\alpha_{\mathbb{Q}}' = \pi J' \frac{r}{D} \tag{19}
$$

It is desirable to define the rotation constant in terms of basic wind-tunnel fan information. Thus,

$$
P = 2\pi n Q = 2\pi n \rho n^{2} D^{5} B \int_{(r/D)_{Q}}^{0.5} Q^{i} d\left(\frac{r}{D}\right)
$$

$$
P = 2\pi \rho n^{3} D^{5} B \qquad \int_{r}^{0.5} T J \frac{r}{D} d \left(\frac{r}{D}\right)
$$
  

$$
P = T B n^{2} D^{2} \left[2\pi \rho D^{2} \qquad \int_{r}^{0.5} V \frac{r}{D} d \left(\frac{r}{D}\right)\right]
$$
  

$$
2\pi \rho D^{2} \qquad \int_{r}^{0.5} V \frac{r}{D} d \left(\frac{r}{D}\right) = M
$$

$$
\tau = \frac{P}{(nD)^2 B M} \tag{20}
$$

.

.

. .

As might be expected, the rotation constant is also one of the many possible power coefficients.

By use of equation  $(19)$ , other blade-element coeffiients become .,  $\sim 10^{11}$  km s  $^{-1}$ 

$$
K = \frac{C_{\text{L}} \frac{b}{D}}{2 \sin^{2} \phi \cos \gamma} = \frac{7}{J' \sin \left(\phi + \gamma\right)}
$$

$$
C_{\text{L}} b = \frac{2D \text{ T} \sin^{2} \phi \cos \gamma}{J' \sin \left(\phi + \gamma\right)}
$$
(21)

 $\overline{a}$ 

$$
1 > \cos \gamma > 0.998

# NACA Technical Note No. 820

j.

The accompanying absolute dynamic pressure increment is

If countervanes are used, the increment in static. pressure is constant over the entire fan.

The assumptions upon which the coefficient derivations are based do not hold in practice. Wind-tunnel fans work in air, a viscous compressible fluid. Owing to viscosity a boundary layer having a radial gradient of axial volocity exists. This distortion of the axial volocity pattorn is independent of the influence of the fan and makes null the conclusion that the total pressure is constant for all streamlines. Because mass flow through every cross section of the system must be the same, the compressible air must docelorate slightly during passage through the fan into a rogion of higher pressure. The fact that profile officioncy is loss than unity has alroady been discussed. None of these discrepancies is believed to be of sufficient consequence to invalidate the reasoning by which the derivations were obtained.

15

 $(23)$ 

 $(24)$ 

The defined coefficients are readily applicable to fan design and performance estimation.

#### INFLUENCE OF WIND-TUNNEL DESIGN ON FAN DESIGN

The dosign of the optimum fan for a wind tunnel depends more upon the decisions of the wind-tunnel designer than upon those of the fan designer. When the driving power, volume flow, fan diameter, and hub-housing diameter have been chosen, the efficiency of the fan is fixed. Relation between driving power and volume flow is expressed by the "oncrgy ratio" of the wind tunnel, which is the ratio of power in the air in a cross section of the test jet to power input to the fan.

$$
\mathbf{E} = \frac{\frac{1}{2} \rho_{\mathrm{T}} A_{\mathrm{T}} V_{\mathrm{T}}^{\mathrm{s}}}{P}
$$
 (25)

In order to estimate the power required to produce a given throat velocity, the designer must first estimate the energy ratio. The estimation of the energy ratio of a return flow wind tunnel is treated in reference 4. Although procodure based on drag estimation and expansion ratio may be followed to determine the energy ratio of a wind tunnel. estimation from experience is usually relied on.

For a given volume flow and blade-tip speed, the rotational efficiency can be shown to improve as the ratio of hub-housing diameter to fan diameter  $D_0/D$  increases. Rotational efficiency for the entire fan, assuming a uniform axial-velocity distribution, can be expressed as

 $\eta_R = 1 - \frac{P}{(\pi n D)^B M} \left[ \frac{\log \frac{L}{D_0/D}}{1 - \left(\frac{D_0}{D}\right)^B} \right]$ 

 $(36)$ 

 $\sqrt{2}$ 

 $\mathbf{r}$ 

The derivation of this expression is given in appendix C, and the function of  $D_0/D$  is plotted in figure  $3.$ 

Change in the ratio  $D_0/D$  may also be made to influence the profile efficiency of the fan. Profile efficiency for a single blade element, tan  $\phi$ /tan  $(\phi + \gamma)$ , is shown, in reference 2, to be greatest when

#### NACA Technical Note No. 820

$$
\phi = 45^{\circ} - \frac{\gamma}{2}
$$

The value of Y can be estimated with very small error. If volume flow, fan diameter, and rotational speed are fixed, an arrangement similar to that shown in figure 4 will give high profile cfficiency as woll as high rotational officiency. The abrupt increase in tunnol-wall diametor pormits the use of the prodetermined large-diameter fan at a location where the air velocity (assumed uniform) will at some nean radius give a desirably large helix angle. The hub housing is shaped to proserve the continuity of flow area for the correct rate of diffusion.

Limitations to the gain in efficiency obtainable by increasing  $D_0/D$  must be learned by experience. The divorgence of the wind-tunnel wall ahead of the fan should not be so abrupt as to cause the flow to separate from the tunnel wall. If countervanes are to be used in conjunction with the fan, the rotational efficiency becomes of secondary interest because the rotational loss is regained except for the small profile loss in the countervanes themselves. Presumably the adverse effect of increased wetted area would, at some point, offset the benefit of increased efficiency. Influence of the hub-housing diameter ratio  $D_0/D$  is discussed in reference l.

### OPTIMUM FAN DESIGN

L

"Optimum fan" here implies a fan whose blade elements work at the highest lift-drag ratio of the airfeil section. A distribution of axial volocity undistorted by the fan is also implied. Design of a wind-tunnel fan is begun with the information furnished by the wind-tunnel designer: volume flow, air density, drive power, shaft speed, fan diameter, and hub-housing diameter. The number of blades used is assumed not to influence aerodynamic behavior of the fan and is to be determined chiefly from considerations of blade strength. Blade interference and number of blades are dealt with in reference 1 and blade strength is discussed in reference 5. Choice of number of blades completes the information noeded to compute the rotation constant of the fan. From equation (20)

 $T = \frac{P}{(nD)^2 B M}$ 

The first assumption to be made by the designer must be with regard to the distribution of axial velocity through the fan. An axial-velocity distribution\_can be established by a judicious use of information contained in references 6 and 7. This procedure invelves computation of the velocities in the boundary layer near a wall and in the vicinity of a body of given shape and adjustment of the velocities to give the correct volume flow. After much work. however, the designer will still have only an approximation. For most wind-tunnel-fan designs, the assumption of uniform axial velocity reduces labor and, except in extreme cases, does not introduce serious error. Determination of helix angle, blado shape, and blado twist is more or less straightforward and is adapted to tabulation.

The helix angle for each radial station can be computed from the definition.

$$
\phi = \tan^{-1} \frac{y}{2\pi rn - \frac{w}{2}}.
$$

If equation (23) is substituted for Ø becomes a  $W<sub>1</sub>$ function of J' and T.

$$
\phi = \tan^{-1} \frac{\gamma}{nD} \left[ \frac{1}{2\pi \frac{r}{D} - \frac{TB}{4\pi \frac{r}{D}}} \right] = \tan^{-1} J \left[ \frac{1}{2\pi \frac{r}{D} - \frac{TB}{4\pi \frac{r}{D}}} \right] \qquad (27)
$$

After selection of the blade airfoil profiles, blade shape and orientation can be determined from equation (21).

$$
C_{\text{L}} b = \frac{2D \text{ T} \sin^2 \phi}{J \sin (\phi + \gamma)}
$$

Either lift coefficient or blade width may be arbitrarily chosen. For the optimum fan; the lift coefficient is chosen to correspond to the smallest value of the  $D/L$ ratio, shown by airfoil characteristics, and the blade width is computed. If the blade-width distribution is fixed, as is sometimes desirable from strength considerations, the lift coefficient can be computed by successive approximations made with successively assumed values of Y. Usually two approximations give the correct lift coeffi-

 $\Gamma_{\rm{max}}=1.5$ 

 $\mathcal{L}^{\mathcal{L}}$ 

 $\bullet$ 

cient,  $\pm 0.005$ , and the corresponding  $\gamma$  checks the assumed value within  $\pm 0.05^{\circ}$ . Airfoil characteristics determine the angle of attack along with the lift coefficient and Y. Because there is usually only a small clearance between blade tip and duct wall, it is assumed that no tip vortices are shed from the blades of a fan working in a duct. On the basis of this assumption, flow about the blade profile is two-dimensional and airfoil characteristics for infinite aspect ratio are used in computing fan characteristics. The blade angle is the sum of the angle of attack and the holix angle.

Two expressions each are available for elemental torque and thrust coefficients:

 $\sim$   $\sim$   $\sim$   $\sim$   $\sim$ 

$$
C_{Q} = T J \frac{\overline{D}}{\overline{D}}
$$
  

$$
C_{Q} = (J')^{2} \left( \frac{C_{L} \frac{\overline{D}}{\overline{D}}}{2 \sin^{2} \phi \cos \gamma} \right) \frac{r}{\overline{D}} \sin (\phi + \gamma)
$$
  

$$
C_{T} = \frac{T J!}{\tan (\phi + \gamma)}
$$

 $C_{T}$ <sup>1</sup> =  $(J')^{2}$   $\frac{C_{L} \frac{b}{D}}{2 \sin^{2} \phi \cos \gamma}$  cos  $(\phi + \gamma)$ 

Use of both expressions serves as a check on computations. Integration of the elemental coefficients gives the corresponding fan coefficients.

$$
C_{Q} = B \int_{r_0/D}^{0.5} C_{Q} \cdot d \left(\frac{r}{D}\right)
$$

$$
C_{T} = B \int_{r_0/D}^{0.5} C_{T} \cdot d \left(\frac{r}{D}\right)
$$

For any distribution of axial velocity, over-all fan efficiency is the ratio of the useful work to the work input.

 $\mathbf{v}$ 

 $\frac{1}{2}$ 

 $\pmb{\mathsf{I}}$ 

The torque and thrust increments are given in equations.  $(2)$  and  $(6)$ .

$$
\eta = \frac{\int_{r_0/D}^{\circ \cdot 5} v \rho n^2 D^4 B C_T i d \left(\frac{r}{D}\right)}{\int_{r_0/D}^{\circ \cdot 5} 2\pi n \rho n^2 D^5 B C_Q i d \left(\frac{r}{D}\right)}
$$

$$

# FAN-PERFORMANCE ESTIMATION

Performance estimation, as opposed to design, includes the determination of power absorbed, thrust, mass flow, and efficiency of a fan, the size and the shape of which are already known. Fan performance, as well as design, depends directly upon the energy ratio of the wind tunnel in which tho fan works. The method of porformance estimation outlined" here is based on the following assumptions: (1) At any given time,"all elements of a fan operate at the same value of the rotation constant; (2) the distribution of axial velocity through the fan is controlled by the fan itself; and (3) a different distribution exists for each value of the rotation constant. This procedure is as applicable to variable-pitch fans as to those having fixed blades, and in the case of either is laborious.

When information at hand consists only of the dimensions of the fan and the wind tunnel and the energy ratio of the wind tunnel, the analyst knows nothing of the fan's operation except that a certain thrust will accoapany a certain mass flow. This fact is known from the wind-tunnel characteristics and leads to the following equation. (for derivation, see appendix D):

$$
\sigma_{\rm T} = \lambda \left(\frac{\sigma_{\rm Q}}{\tau}\right)^2 \tag{29}
$$

where the fan wind-tunnel constant

. .

.

.-

,

.

.

i. :<br>:

$$
\lambda = \frac{\eta_{\text{design}}}{E A_{\pi} B^2} \left(\frac{\rho_{\text{F}} A_{\text{F}}}{\rho_{\text{T}} A_{\text{T}}}\right)^2
$$

The design efficiency  $\eta_{\tt{design}}$  in the foregoing expression is the fan efficiency that was assumed in computing the energy ratio.

The relation involving the thrust-torque-rotation constant, expressed by equation (29), coupled with the pertinent assumption that all blade elements operate at the same value of tho rotation constant at a given instant furnishes means for a systematic analysis. Tho first stop is to prepare, for each  $r/D$  station, charts of  $C_Q$ <sup>t</sup> and  $C_T$ <sup>t</sup>

plotted against J! (fig. 5). These charts show values of  $O_Q$ ',  $O_T$ ', and J' for constant blade angles and for constant values of the rotation constant T.

Basic design information will show whether the blade angles are fixed or variable and will indicate the range of J' and T over which the blade clements will be roquired to work. One set of computations fixes  $C_0$ <sup>1</sup>,  $C_{\overline{u}}$ <sup>1</sup>, and the blade angle for a series of assumed J' values at one value of  $\tau$  at one  $r/D$  station. For the given  $r/D$ station, a reasonable value of  $\tau$  is chosen and several J' values are selected, which bracket the working range of the section. An outline of a sample computation preparing  $O_0!$  and  $O_m!$  charts follows.

 $\lambda$  chart

 $24$ 

### NACA Technical Note No. 820

When values of  $C_0$ <sup>1</sup> and  $C_T$ <sup>1</sup> are plotted, the corresponding values of the blade angle are noted. The foregoing computation must be repeated for enough values of T to cover the working range of the fan. Curves for constant<br>values of T can be faired directly. Curves for constant blade angles must be faired by interpolating the values noted in plotting. . Similar charts must be prepared for fivo or  $\texttt{six}$   $\texttt{r/D}$  stations.,

Consider performance estimation for a fixed-patch fan. The blade angle at each  $r/D$  station will be known. For the proper blade angle at each r/D station, read from the  $C_0$ <sup>1</sup> and  $C_{\mathcal{P}}$ <sup>1</sup> charts values of  $C_0$ <sup>1</sup> and  $C_{\mathcal{P}}$ <sup>1</sup> corresponding to a single value of T. The value of J' will vary from station to station if the distribution of axial velocity is not uniform. Integrate  $C_{Q}$ ' and  $C_{\underline{m}}$ ' to get and  $O_{\pi\bullet}$  Repeat the foregoing procedure for two other  $\sigma_{\Omega}$ values of  $\tau$  and plot  $C_T$  against  $\left(\frac{C_Q}{T}\right)^{-}$ . On the same chart plot equation (29). The intersection of the two curves, shown in the following diagram called the  $\lambda$  chart, gives  $O_Q$ ,  $O_T$  and, by interpolation, gives the  $T$  value under which the fan operates at the specified blade-angle sotting.

The chart shown is for a variable-pitch fan. For a fixed-pitch fan only one  $\beta_0$  curve exists.

Tabulate encircled points on  $\lambda$  chart and compute the efficiency and the mass flow. The form following is a simple one for this purpose:  $\alpha = \alpha_1 + \alpha_2$ 

25

#### 26 NACA Zochnical' Noto No-. 820

Further desirable information includes the efficiency, the axial-velocity distribution, and the mass flow, Axialvelocity distribution varies directly as J1. As the working T is now known, as well as the blade angle, values of  $C_m$ <sup>I</sup> and J<sup>1</sup> can be taken directly from the  $C_m$ <sup>I</sup> charts and the integrated product J' C<sub>T</sub>' can be used in equation  $(28)$  to determine the fan efficiency. Mass flow can be computed from equation (30), which is derived from the definition of the rotation constant.

$$
M = \frac{2\pi \rho_{\rm F} D^2}{B} n \frac{G_0}{T}
$$
 (30)

..

-.

. .

".

**",**

Throat velocity must be computed from the mass flowe Inasmuch as fan diameter D is included in the primary information, all performance characteristics are now known in terms of shaft speed. n. The shaft speed depends entirely on the type of driving power rotating the fan. If the type of driving power is known, the thrust, the power, the efficioncy, and tho mass flow can bo found iumodiatoly for one blado-anglo setting.

If the wind-tunnel fan is of the variable-pitch type, analysts at each of a series of blade-angle settings will be necessary. The  $\lambda$  chart will then carry a curve for each blade-angle setting as shown, Becauso the distribu. tion of axial velocity through the fan is assumed to be nonuniform and to vary with oporating conditions, tho slip function  $V/nD$  losos some of its meaning. Bettor paramoters for expressing wind-tunnel fan characteristics are blado anglo  $\beta$  or rotation constant T. Final information, including shaft spood, powor, thrust, efficiency, and volumo flow, again is dopendont upon the type of driving power.
