Chapter I

Introduction

A. Background

This report documents the work accomplished by the University of Dayton, School of Engineering, under NASA grant NAG-1-1327 during the first two years of the research effort. Work accomplished during the first year is also documented in the report entitled "The Determination of Operational and Support Requirements and Costs during the Conceptual Design of Space Systems," dated June 18, 1992 [23].

The purpose of the grant is to provide support to NASA in predicting operational and support parameters and costs of proposed space systems. Specific research objectives include:

(1) the development of a methodology for deriving reliability and maintainability (R&M) parameters,

(2) based upon R&M estimates determine operational capability and support requirements,

(3) the identification of data sources and the establishment of an initial data base to support the methodology, and

(4) implementation of the methodology through the development of a comprehensive computer model.

B. Summary of Research Effort

The first year's research developed a methodology for deriving reliability and maintainability parameters of conceptual space vehicles and for applying these parameters in establishing manpower and spares requirements. The methodology was based upon the use of regression analysis to establish empirical relationships between aircraft performance and design specifications and corresponding mean time to failures and mean repair times. Adjustments were then made to account for the different environment in which space vehicles must operate. This methodology was applied to a large data base consisting initially of 35 military aircraft and implemented through the use of a personal computer (PC) model.

The second year focused on three major areas:

(1) enhancements to the methodology,

(2) increased scope of the model, and

(3) software improvements.

Additional work also included the transfer of all input and computed data files into an EXCEL spreadsheet format for easy access by NASA personnel. This will support future updates to the equations and parameters utilized by the model.

Enhancements to the methodology include:

(1) Performing the analysis at a lower work breakdown structure (WBS). This increased the number of subsystems addressed by the model from 16 to 33. An avionics roll-up is also performed. Additional regression analysis was performed at the lower level to develop new parametric equations.

(2) Incorporating subsystem redundancy into the reliability calculations including a more general k out of n redundancy for engine, power, and avionics subsystems.

(3) Computing subsystem and system reliabilities at key milestones during a mission. These include reliability at launch, at booster separation, at orbit insertion, at reentry, and at mission completion.

(4) Subsystem weights may be input directly or computed from a total dry weight based upon a specified weight distribution. Four different distributions corresponding to a small vehicle, a large vehicle, the shuttle, and a computed aircraft distribution may be used.

(5) The option to specify directly the MTBF's, MTTR's, abort rates, removal rates, crew sizes, and on/off subsystem manhour percentages rather than have these values computed from parametric equations.

(6) The addition of a sixth segment in the mission profile and subsystem operating hours consisting of a ground recovery and processing time. Unlike pad time, this ground operational time does not impact upon the mission reliability calculations but is considered when computing total failures and scheduled/unscheduled maintenance workload as well as vehicle turn time.

(7) The failure rate of the landing gear system was changed from operating hours to a cyclical measure (per mission).

(8) Vehicle turn time calculations now include a minimum turn time under the assumption of parallel maintenance tasks on all subsystems. Integration time and pad time are included as part of the turn time. Turn time is based upon one, two and three shift maintenance schedules.

(9) Scheduled maintenance is determined as a percent of the on-equipment unscheduled maintenance rather than as a percent of the total unscheduled maintenance.

(10) The addition of a variable representing the number of assigned crews by subsystem. This allows for parallel tasks to be accomplished in determining vehicle turn times.

The scope of the model was increased with the following:

(1) A more detailed work breakdown structure which uniquely identifies 33 subsystems.

(2) The addition of an optional (liquid) booster rocket as part of the overall system with both reliability and maintainability parameters computed.

(3) The addition of an optional external fuel tank as part of the overall system with both reliability and maintainability parameters computed.

(4) The incorporation of space shuttle mean time between failure (MTBF), mean time to repair (MTTR), removal rate, and crew size data into the analysis. The user has the option of selecting by subsystem, shuttle data, computed (aircraft) data, or direct input of data for use in the analysis.

(5) Manpower is now computed in three ways based upon aggregated (vehicle) manhours per month, subsystem manhours per month, and subsystem crew size requirements.

Software enhancements to the model include:

(1) A complete redesign of the user interface providing a menu driven navigation path rather than sequential input.

(2) The addition of an error trapping routine to prevent unnecessary aborts resulting from non-fatal input/output errors.

(3) The use of a compiled version of the computer model to increase speed and portability.

(4) Increase modularization of the code through the use of subprograms under the Quick BASIC environment. This was necessary to utilize additional core memory needed to provide more input options and handle the increased scope.

(5) The addition of a system performance summary report to provide vehicle level summary output without having to navigate through each of the detailed output reports.

(6) The addition of a weight factor to support sensitivity analysis. This factor permits a specified percent increase or decrease in weights across all subsystems.

(7) Assigning file names based upon vehicle/project names rather than inputting additional file names.

(8) Subsystem names may be changed thereby allowing for the addition of new subsystems so long as the total number of subsystems does not exceed 33.

C. Scope of Research

This follow-on effort expands the prediction of reliability and maintainability (R&M) parameters and their effect on the operations and support of space transportation vehicles to include other system components such as booster rockets and external fuel tanks. It also increases the scope of the methodology and the capabilities of the model as implemented by the software. The focus is on the failure and repair of major subsystems and their impact on vehicle reliability, turn times, maintenance manpower, and repairable spares requirements.

Chapter II documents the data utilized in this study. Chapter III outlines the general methodology for estimating R&M parameters and for relating these parameters to the logistics support and operational requirements of the proposed vehicle. Chapter IV presents the analysis and results of applying the methodology to the initial data base while Chapter V describes the implementation of the methodology through the use of a computer model. The report concludes with a discussion on validation and a summary of the research findings and results.

Chapter II.

Data Sources

The principle approach to be used in establishing R&M estimates of new space systems is based upon comparability with existing systems. In this regard, many of the subsystems defined for manned space vehicles may be favorably compared to corresponding aircraft systems. Therefore, a primary source of data to support this analysis are aircraft failure and repair data. A secondary source of data is the space shuttle obtained through data collected by Martin-Marietta Corporation [22].

A. Reliability and Maintainability Data

Data requirements consist of the following R&M data pertaining to all relevant aircraft and space shuttle subsystems.

The primary R&M data are:

(1) Mean time between maintenance (MTBM). This is defined to be the length of time in flying hours between maintenance actions on a particular subsystem or component. Only unscheduled maintenance actions are included. A distinction is made between maintenance actions and failures. Maintenance actions include inherent failures (subsystem failures), induced failures (external failure causes) and no defect found or cannot duplicate actions.

(2) Maintenance manhours per maintenance action (MH/MA). This is the primary measure of maintainability used in this study. Along with the number of maintenance actions per mission (obtained from the MTBM), it becomes the basis of the maintenance requirements.

(3) Maintenance Task Times. The length of time (usually in hours) to perform a particular task such as troubleshoot, remove and replace, perform minor maintenance, etc. This maintainability parameter is usually summarized at the subsystem or component level as the Mean Time to Repair (MTTR). In this study, aircraft task times are obtained by dividing the MH/MA by an average crew size. For the space shuttle, MTTR's are derived directly from the Martin-Marietta data.

(4) Maintenance crew sizes. The number of maintenance personnel required to perform a particular task. This number may vary depending upon the task, the particular component involved and the skill level of the personnel. An average crew size is determined by subsystem. A related variable, the number of crews, assumes each crew consists of the average crew size.

(5) Removal rates (RR). This is the percent of maintenance actions which results in a removal and replacement of a component from the aircraft. It is the basis for establishing demand rates for spare components.

(6) Abort rates (AB). This is the percent of maintenance actions which results in a ground or air abort. This rate is used to establish a critical failure rate which in turn is used to compute the mission reliability.

(7) Percent off equipment (POFF). This is the percent of the total unscheduled maintenance manhours performed on components removed from the aircraft. These hours do not delay processing the vehicle. Therefore 1-POFF, or the percent of on-aircraft work, is used in determining the vehicle turnaround time.

B. Military R&M Data Systems

(1) US Air Force data systems

Reliability and maintainability data for USAF aircraft originates with the Maintenance Data Collection (MDC) system as described in AFM 66-1. This data is collected at the base (squadron/wing) level (AFTO Form 349) and transmitted periodically to AF Material Command (AFMC). AFR 65-110 data (aircraft status reporting) reports flying hours and sorties for the same bases monthly. The D056 Product Performance System processes this data producing several R&M reports. D056 also provides data to the Maintenance and Operational Data Access System (MODAS) for on-line viewing and retrieval. AFALD Pamphlet 800-4, Aircraft Historical Reliability and Maintainability Data summarizes the worldwide R&M data at the two-digit work unit code (WUC) in 6-month intervals. Currently Volumes I through VI covering the years 1972 through 1989 have been published. Volume VII has not been published and the consolidation of the data systems into REMIS place the continued publication in jeopardy.

The current OPR for AFALDP 800-4 is ALD(AFMC)/LSR, Wright-Patterson AFB, Ohio. However, with the consolidation of AFLC and the Air Force Systems Command (AFSC) to form Air Force Material Command (AFMC), this office may be eliminated. With the eventual implementation of REMIS (Reliability and Maintainability Information System), the D056 system along with MODAS will also be eliminated. As of May 1993 MODAS is still operating under a day-to-day extension. Both REMIS and MODAS were to operate in parallel until August 3, 1992 when MODAS was to be eliminated. They are still (June 1993) operating in parallel with limited support of the MODAS system. It is not certain at this time what the final configuration and capabilities of REMIS will be.

The MODAS system (G063) is currently sponsored by AFMC(I)/ENIS, Wright-Patterson AFB, Ohio 45433. MODAS provides the user with access to various data bases through an interactive menu driven system. It is a Data Base Management System (DBMS) with some automated analytical capability. R&M information may be displayed by aircraft (MDS), WUC, level of WUC, base, and by month.

(2) US Navy

The primary source of R&M data pertaining to Navy aircraft is the Aviation 3-M Information reports. The Navy Maintenance Support Office (NAMSO), is the central data bank for Aviation 3-M data (Maintenance and Material Management system). NAMSO is part of the Naval Sea Logistics Center. Although preformatted reports are published monthly, quarterly and annually, and are available on request, a potential user may also request the development of a new report. Most reports can be obtained on either hard copy or microfiche. Magnetic tape may be obtained under a special request.

The following two R&M reports have been utilized in this research.

Report Title	Report Number
Reliability and Maintainability Summary	NAMSO 4790.A7142-01
WUC System R&M Summary	NAMSO 4790.A7142-02

The R&M Summary Report provides data similar to that available from the MODAS system. Summary statistics are reported by aircraft type at the 5-digit WUC and include mean flying hours between maintenance actions, maintenance manhours per flying hour, maintenance manhours per maintenance action, and elapsed maintenance time per maintenance action.

Of particular interest in this research is the WUC System R&M Summary. This report provides mean flying hours between maintenance actions, maintenance manhours per flying hour, maintenance manhours per maintenance action, and elapsed maintenance time per maintenance action by system level WUC (2-digit) for all appropriate aircraft.

C. Shuttle Data Source

R&M data pertaining to the Space Shuttle operations was obtained from a Martin Marietta Corporation study (NASA Contract NAS1-18230) and documented in a final report: "Space Station Definition, Design and Development, Task 18: Launch Vehicle Maintenance Analysis," November 1992 [22]. Data used in this study included maintenance actions, remove and replace actions, operating hours, MTBM's, MTTR's, and crew sizes. In general, these parameters were obtained for 21 different subsystems covering shuttle missions STS 31 through STS 49 (excluding STS 34, 46 & 47). A limited amount of data was obtained on the Titan expendable launch system and the external tank system. All data elements were aggregated by subsystem and are summarized in Appendicies B, C, and D. Overall averages computed from the Martin Marietta data provided default shuttle input values to the model.

D. Aircraft Performance and Design Specifications

In addition to R&M data, aircraft performance and design specifications (Table 1) were necessary to support the parametric analysis. A primary source of this data for military aircraft was a technical report titled "Modular Life Cycle Cost Model for Advanced Aircraft Systems Phase III," prepared by the Grumman Aerospace Corporation [15] for the Flight Dynamics Laboratory, Wright-Patterson AFB, Ohio. This report documents the data base used in developing a life cycle cost model for the proposed aircraft.

Table 1
Aircraft Design/Performance Variables[1]

VEHICLE DRY WEIGHT	VEHICLE LENGTH
WETTED AREA	VEHICLE WING SPAN
FUSELAGE VOLUME	SUBSYSTEM WEIGHTS

MISSION LENGTH	OPERATING CEILING
NUMBER OF WHEELS	NUMBER ACTUATORS
NUMBER CONTROL SURFACES	MAXIMUM ELECTRICAL OUTPUT
NUMBER HYDRAULICS SYSTEMS	NUMBER AVIONICS SYSTEMS
BTU COOLING CAPACITY	AVIONICS INSTALL WEIGHT

Subsystem weights used in this study were obtained from the Design Branch of the Plans and Programs Directorate of the Wright Laboratories at Wright-Patterson AFB (WL/XPAD). Secondary data sources included all volumes of Jane's All The World's Aircraft [13], Aviation Week & Space Technology [3], and Observer's Directory of Military Aircraft [8].

E. Initial Data Base

The primary source of military R&M data is the Air Force AFM 66-1 Maintenance Data Collection (MDC) system and the Navy 3-M data system. The initial data base consisted of AF MDC data as reported in Volume V (October 1985 to September 1987) of AFALDP 800-4 and Navy data reported in the July 1990 - June 1991 R&M Summary Report. Volume VI of AFALDP 800-4 (October 1987-September 1989) and the MODAS on-line system (January 1990-December 1991) were secondary sources. AFALDP 800-4 summarizes R&M data at 6-month intervals. Four 6-month periods were averaged together in order to provide more accurate measures. The Navy data is presented by quarters. Four quarters were averaged

[1] Variable definitions of those used in the model are in Appendix E.

together also to provide for more accurate MTBM's and manhours. Table 2 lists the 37 Air Force and Navy aircraft used in the study and Table 3 identifies the 28 major aircraft subsystems which were included. These subsystems are identified by two-digit work unit codes (WUC).

Chapter III

Methodology

A. Parametric Analysis

The primary objective is to develop a methodology for estimating reliability and maintainability parameters for use in life cycle costing, supportability requirements determination and the assessment of operational capabilities and constraints of proposed space vehicles. This methodology utilizes the available data sources identified in the previous chapter. The approach is based upon a comparability analysis with similar aircraft subsystems. By estimating aircraft equipment failure and repair parameters as a function of performance and design specifications, then, with suitable adjustments to account for the differences in operating environment, the R&M parameters of a conceptual space vehicle may be estimated based upon its design and operating specifications. Adjustments are also necessary to account for technological innovation over time. This chapter presents the mathematical foundation for the analysis performed on the data base and described in the following chapter.

Parametric R&M equations are derived using regression analysis. In general, let

$$Y = B_0 + B_1 X_1 + B_2 X_2 + \ldots + B_k X_k \tag{1}$$

where Y = R&M parameter of interest (e.g. MTBF or MH/MA)

and X_j = jth design or performance specification (e.g. vehicle dry weight), $j = 1, 2, \ldots k$,

then

$B_0, B_1, \ldots, B_k$ are the regression coefficients.

These are estimated by performing a least-squares fit of the equation against known paired values for Y and the corresponding $X_1, X_2, \ldots, X_k$ obtained from the data base.

The following R&M parameters have been estimated using this approach:

MTBM - Mean Flying Hours between Maintenance Actions

MH/MA - Maintenance Manhours per Maintenance Actions

RR - Subsystem removal rate

POFF - Percent off-equipment (vehicle) manhours

CREW - Average crew size per maintenance task

AB - Abort Rates (Critical Failure Rate)

In addition to the above R&M parameters, regression equations were derived to estimate subsystem weights and design/performance variables (see Table 1) as functions of the vehicle **dry weight** and **length + wing** span. The variables in Table 1 are classified as secondary variables while the **dry weight** and **length + wing** span are classified as primary variables. Using these equations, it is possible to estimate all of the necessary R&M parameters using only a small number of primary (driver) variables. First subsystem weights are determined from the regression equations, or from a set of relative percentages of the vehicle dry weight, then the secondary variables are computed from their equations, and finally the MTBM, MH/MA and other R&M parameters are estimated from their regression equations. The latter equations will include subsystem weights and those secondary variables which were found to significantly improve upon the prediction capability. For those subsystems analyzed using shuttle data, the initial MTBM, RR, AB, MTTR, and crew values are input directly rather than computed from the parametric equations.

B. Computation of MTBM

An initial MTBM is obtained by subsystem from the derived parametric estimating equations. The MTBM is in units of operating (flying) hours between maintenance actions and reflects a subsystem operating in an aircraft (air/ground) environment.

(1) Technology Growth Factor

In order to account for increased reliability as a result of technological change over time, a growth factor was computed. First, the learning curve effect on the reliability of a subsystem over time was estimated. The learning curve accounts for engineering changes, modifications, and other reliability burn-in phenomena associated with a system maturing over time. This was accomplished by fitting an equation of the form:

$$MTBM = a\ T^{b} \qquad (2)$$

where: T = cumulative calendar time or cumulative operating (flying) hours and "a" and "b" are parameters estimated using least-squares.

Next, a technology adjustment factor was found by averaging several pair-wise comparisons between aircraft developed during different technology periods but having similar missions and requirements. An MTBM for both aircraft was obtained from the data set (generally a two-year average value). The MTBM of the newer aircraft was modified using the learning curve growth rate (b) to account for the differences in age between the two systems. That is,

$$\text{Mod MTBM} = a \times (1986 - \text{Dev YR Old ACFT})^{b} \qquad (3)$$

where solving Equation (2) for "a" provides:

$$a = \text{NEW ACFT MTBM}/(1986\text{-DEV YR NEW ACFT})^{b} \qquad (4)$$

The baseline year for the aircraft data is 1986 and the MTBM reflects the baseline year. When applying the technology growth factor to Shuttle MTBM's, a baseline year of 1992 is used, reflecting the technology age of the Martin Marietta data. The "a" parameter defines the units (e.g. operating hours or years) while the "b" parameter describes the rate of growth.

The adjustment factor was then found by solving the compound growth rate curve:

$$\text{MOD MTBM} = \text{OLD ACFT MTBM} \times (1+\text{ADJ FAC})^{\text{AGE DIFF}} \quad (5)$$

That is,

$$\text{ADJ FAC} = [\text{MOD MTBM/OLD ACFT MTBM}]^{(1/\text{AGE DIFF})} - 1 \quad (6)$$

This factor was then used in adjusting the initial MTBM to account for technological growth in reliability between the baseline year of the data and the expected development year of the proposed system. That is

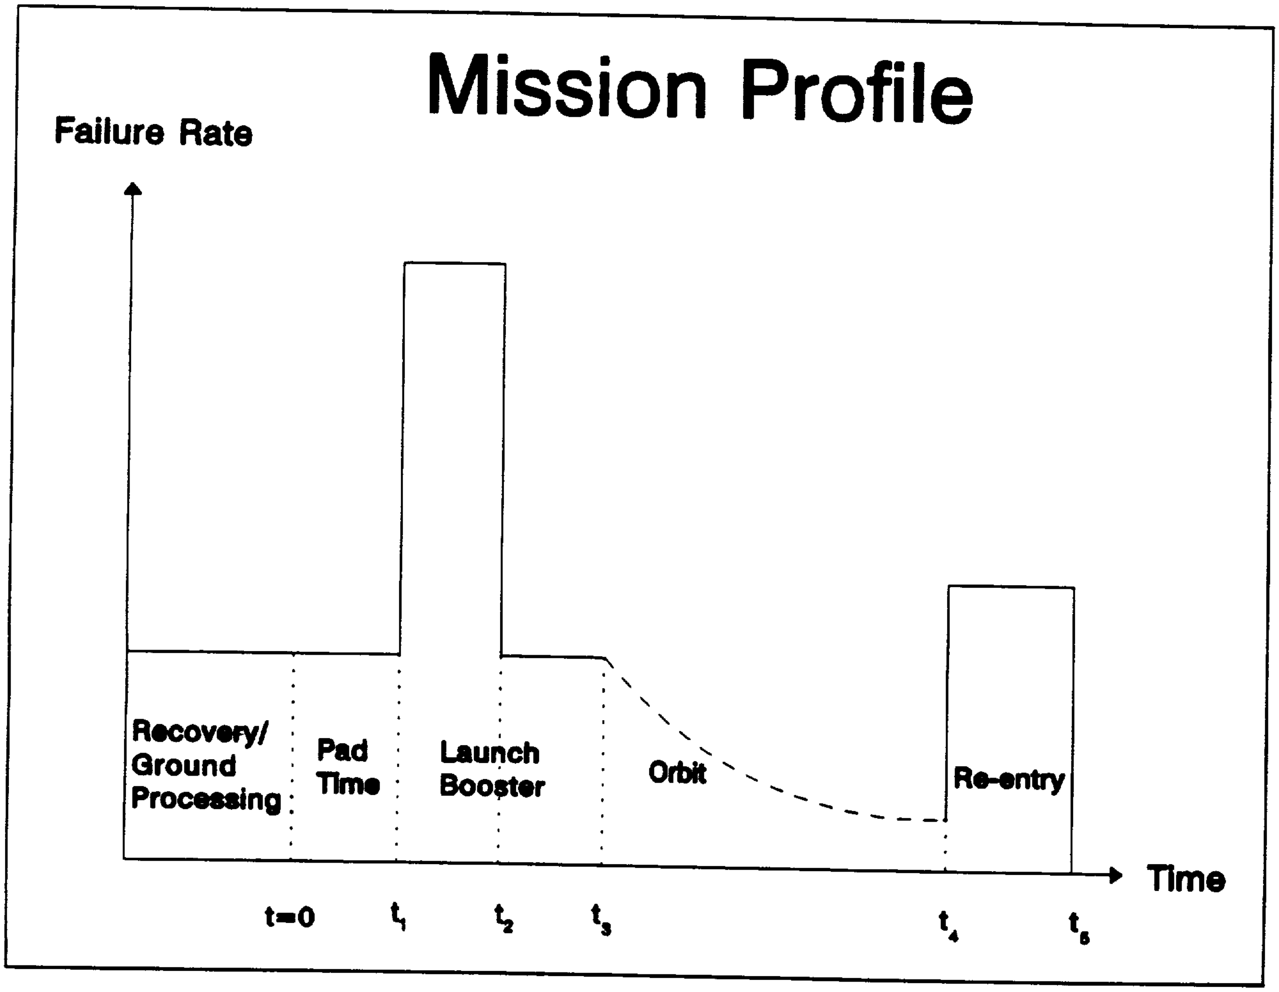
$$\text{ADJ MTBM} = \text{MTBM} \times (1+\text{ADJ FAC})^{(\text{yr}-1986)} \quad (7)$$

(2) Environmental Adjustment

A further adjustment to the MTBM was then made to account for the change in failure rates (from those of the aircraft air/ground environment) during launch and orbit. During the air (non-booster launch and re-entry phase) and ground phase, failure rates are assumed to be constant (exponential) with a MTBM based upon the ADJ MTBM defined above. However, during launch under booster rockets, the failure rate may increase dramatically as a result of the increased vibration and stresses. On the other hand, while in orbit, the failure rate is assumed to decrease over time. A Weibull failure rate function was assumed for this portion of the mission. When the MTBM is input directly from the Shuttle derived data, the space adjustment is not performed since the historical MTBM includes operating in the space environment.

For each subsystem, a mission profile curve was assumed having the following form:

Figure 1
Mission Profile



The recovery/ground processing time segment assumes a constant failure rate λ. It is utilized in computing maintenance workload, manpower, spares, and vehicle turn-times. However, it is not used in any of the reliability calculations. For reliability calculations the failure rate curve is based upon the remaining mission profile segments and may be expressed mathematically as:

$$\lambda(t) = \begin{cases} \lambda & for \quad 0 \le t < t_1 \\ \kappa \times \lambda & for \quad t_1 \le t < t_2 \\ \lambda & for \quad t_2 \le t < t_3 \\ \frac{b}{a}\left(\frac{t}{a}\right)^{b-1} & for \quad t_3 \le t < t_4 \\ \lambda & for \quad t_4 \le t < t_5 \end{cases} \tag{8}$$

where:

$$\lambda = \frac{1}{ADJ\ MTBM}$$

$$\kappa = LAUNCH\ FACTOR$$

and a, and b are the Weibull scale and shape parameters respectively, a>0, 0<b<1

Since, in general, a reliability function is given by

$$R(t) = e^{-\int_0^t \lambda(t)\, dt} \tag{9}$$

the reliability function may be obtained from (8) using (9):

$$R(t) = \begin{cases} e^{-\lambda t} & for \quad 0 \le t < t_1 \\ e^{-[\lambda t_1 - \kappa\lambda(t - t_1)]} & for \quad t_1 \le t < t_2 \\ e^{-\lambda[(t + t_1 - t_2) - \kappa(t_1 - t_0)]} & for \quad t_2 \le t < t_3 \\ e^{-\lambda(t_3 + t_1 - t_2) - \kappa\lambda(t_2 - t_1) + \left(\frac{t}{a}\right)^b - \left(\frac{t_3}{a}\right)^b} & for \quad t_3 \le t < t_4 \\ e^{-\lambda(t_3 + t_1 - t_2) - \kappa\lambda(t_2 - t_1) + \left(\frac{t_4}{a}\right)^b - \left(\frac{t_3}{a}\right)^b - \lambda(t - t_4)} & for \quad t_4 \le t < t_5 \end{cases} \tag{10}$$

Since the mission profile is repetitive over time, a steady-state MTBM may be computed from equation (11).

$$\text{SS MTBM} = \frac{\int_0^{t_5} R(t)\,dt}{1-R(t_5)} \tag{11}$$

The use of the Weibull failure distribution in defining R(t) requires a numerical integration to compute the MTBM from Equation (11). In the implementation of the model discussed in Chapter V, Simpson's rule was used to perform the integration.

(3) Critical MTBM

Using aircraft air and ground abort rates (AB), subsystem regression equations were derived to provide estimates of critical failure rates. A critical MTBM was then obtained from

$$\text{CRIT MTBM} = \text{SS MTBM/AB} \tag{12}$$

A vehicle MTBM is calculated from the subsystem MTBM's using:

$$\text{VEH MTBM} = 1/[1/\text{MTBM}_1 + 1/\text{MTBM}_2 + \ldots + 1/\text{MTBM}_k] \tag{13}$$

where $1/\text{MTBM}_i$ is the failure rate of the ith subsystem[2].

C. Reliability Calculations

All reliability calculations are based upon the CRIT MTBM. Letting $\lambda = \frac{1}{\text{CRIT MTBM}}$ for each subsystem, Equation (10) is used to compute a mission reliability at times t_0, t_1, t_2, t_3, t_4, and t_5. Subsystem redundancy is addressed in one of two ways. For most subsystems, reliability is obtained from:

$$R_{s_i}(t) = 1-[1-R_i(t)]^{n_i} \tag{14}$$

where $R_{si}(t)$ is computed from Equation (10) for the ith subsystem and n_i is the number of redundant subsystems of type i. For selected subsystems (engines, power, and avionics), a k-out-of-n redundancy is computed, where k_i is the minimum number of redundant subsystems (of type i) which must be operational. This calculation makes use of the binomial probability distribution and is given by:

$$R_{s_i} = \sum_{x=k_i}^{n_i} \binom{n_i}{x} R_i(t)^x \,(1-R_i(t))^{n_i-x} \tag{15}$$

---

[2] Certain subsystems, such as landing gear, may have failure times based upon cycles (landings) rather than operating hours. When this is the case, the MTBM is converted to mean operating hours between maintenance in order to compute the vehicle MTBM.

A vehicle reliability is computed by multiplying the subsystem redundant reliabilities (R_i)

$$R_{veh} = R_{s1} \times R_{s2} \times \ldots \times R_{sk} \tag{16}$$

D. Maintainability Estimates

The primary maintainability parameter used in this study is the maintenance manhours per maintenance action (MHMA). This parameter is estimated from the parametric regression equations for each subsystem. Then using

$$\text{TOT MA} = 1/(\text{SS MTBM}) \times \text{OPER HRS}^{3} \tag{17}$$

total maintenance actions per mission is obtained and from

$$\text{TOT MANHRS} = \text{MHMA} \times \text{TOT MA} \tag{18}$$

total maintenance manhours per mission is found. Manhours are then split into on-vehicle and off-vehicle manhours using the percent off-equipment hours (POFF) obtained from regression equations:

$$\text{TOT ON-VEH MH} = (1\text{-POFF}) \times \text{TOT MANHRS} \tag{19}$$

$$\text{TOT OFF-VEH MH} = \text{POFF} \times \text{TOT MANHRS} \tag{20}$$

When using shuttle data, MHMA is not computed from the regression equations. Instead:

$$MHMA = MTTR \times CREW + \frac{POFF \times CREW \times MTTR}{1-POFF} \tag{21}$$

where MTTR is a direct input to the calculation and represents the mean time to repair on-vehicle work only.

Scheduled manhours is calculated by multiplying the total on-vehicle MH by a percentage. This percentage may be input directly to the calculation or obtained from a regression equation which estimates the scheduled manhours as a percentage of the unscheduled on-vehicle manhours.

$$SCHED\ MH = PCT \times (TOT\ ON\text{-}VEH\ MH) \tag{22}$$

[3] OPER HRS here includes the Recovery/Ground processing time.

E. Manpower Requirements

Maintenance manpower requirements are determined in three different ways. The first method is to take the total unscheduled manhours of work per month and divide this total by the number of hours per month available per technician to do direct maintenance work.

Let N = number of mission per month,

AV = available hours per month per individual

IND = percent of indirect work (work not included in the MHMA)

then,

$$NBR\ PER = \frac{TOT\ MANHRS \times N}{(1-IND)AV}\ (rounded\ up) + \frac{SCHD\ MH \times N}{(1-IND)AV}\ (rounded\ up) \qquad (23)$$

The second approach uses the same methodology except it is applied by subsystem. That is total manhours represents subsystem manhours and manpower is calculated by subsystem. Since scheduled maintenance is computed only at the vehicle level and not by subsystem, it will not change.

The third approach identifies the crew size by subsystem as a minimum requirement. If the manpower computed from subsystem manhours exceed the minimum crew size requirements, then the larger number should be used. The three methods for determining manpower should provide overall bounds on the total requirement.

F. Spare Parts Requirements

In order to estimate spare parts requirements, it is necessary to distinguish between a failure resulting in a remove and (if a spare is available) replace action versus other maintenance actions such as on-aircraft troubleshoot and repair. The MODAS system identifies maintenance actions by an action taken code one of which is a removal code.

Using regression equations or an estimated Shuttle value, a removal rate (RR) per maintenance action was determined and used to obtain the mean number of demands (failures) for spares (MFAIL) per mission as follows:

$$MFAIL = RR \times (TOT\ MA) \qquad (24)$$

Under the common assumption that the number of failures in a given time period follows a Poisson process, a spare parts level can now be found which will satisfy demands a specified percent of the time. This is the frequently used fill rate criterion which represents the percent of time a demand (failure) can be immediately satisfied from the on-hand stock.

Let S = spare parts level to support a given mission and
p = desired percent of time demands are satisfied (fill rate),
then find the smallest value for S such that $F(S) \geq p$ where

$$F(S) = \sum_{i=0}^{S} e^{-MFAIL} \left[\frac{MFAIL^{i}}{i!} \right] \tag{25}$$

F(S) is the cumulative probability of demands not exceeding the spares level (S).

G. Vehicle Turn Times

In order to determine the time required to perform maintenance on the vehicle, estimates of average crew sizes for typical on-vehicle tasks by subsystem must first be obtained. Once the average crew size has been determined from regression equations or from the data base, an average on-vehicle repair time can be obtained by

$$MTTR = (1\text{-}POFF) \times MHMA/AVG\ CREW \tag{26}$$

or input directly as in the case of the shuttle data. Average on-vehicle subsystem repair time per mission may be found from

$$MSN\ REP\ TIME = \frac{MTTR \times TOT\ MA}{NBR\ CREWS} \tag{27}$$

where NBR CREWS is the total number of crews available to perform parallel work on the subsystem. Assuming tasks, for each subsystem, are performed sequentially (a worst case), then total vehicle mission repair time is the sum of the subsystem repair times:

$$VEH\ REP\ TIME = \sum_{ALL\ SUBSYS} MSN\ REP\ TIME \tag{28}$$

Scheduled maintenance time may then be added to obtain a total vehicle maintenance task time:

$$TOT\ VEH\ TASK\ TIME = VEH\ REP\ TIME + \frac{0.98 \times SCHD\ MHRS}{AVE\ CREW\ SIZE}\ [4] \tag{29}$$

[4] Aircraft data has shown that 98 percent of the scheduled maintenance is on-aircraft maintenance.

Mission, pad, and integration time must be included in order to obtain a vehicle turn-around time. Therefore, vehicle turn-around time in working days is:

$$VEH\ TURNAROUND = \frac{MSN\ TIME + PAD + INTG}{24} + \frac{TOT\ VEH\ TASK\ TIME}{sft \times 8} \tag{30}$$

Equation (30), by including the number of shifts (shft) in the second term will provide a vehicle turnaround time based upon 1, 2, or 3 shift maintenance. Dividing the vehicle turnaround time into the number of working days per month gives an estimate of the number of missions per month per vehicle:

$$MSN/MO/VEH = \frac{WORKING\ DAYS/MO}{VEH\ TURNAROUND} \tag{31}$$

Dividing the required number of missions per month by the number of missions per month per vehicle provides an estimate of the required fleet size:

$$FLEET\ SIZE = \frac{RQD\ MSN/MO}{MSN/MO/VEH} \quad (rounded\ up) \tag{32}$$

Equation (28) implies that all subsystems will be repaired sequentially. Setting TOT VEH TASK TIME (EQ 29) equal to the maximum subsystem MSN REP TIME (or scheduled maintenance time, if larger), a minimum vehicle turnaround time assuming all work may be accomplished in parallel is obtained.

H. ET and LRB Calculations

From input parameters consisting of subsystem MTBM, OPER HRS, CRIT FAIL RT, MTTR, and CREW SIZE, subsystem reliability, scheduled and unscheduled manhours and manpower are computed. Reliability is derived from:

$$R = e^{-\frac{OPER\ HRS}{MTBM/(CRIT\ FAIL\ RT)}} \tag{33}$$

and

$$UNSCH\ MH = \frac{OPER\ HRS}{MTBM} \times MTTR \times CREW\ SIZE \tag{34}$$

$$SCHD\ MH = PCT \times UNSCH\ MH \tag{35}$$

$$MAN\ PWR = \frac{(UNSCH\ MH + SCHD\ MH) \times N}{(1 - IND) \times AU} \quad (rounded\ up) \tag{36}$$

ET/LRB system reliabilities are obtained by multiplying subsystem reliabilities while system manhours and manpower are obtained by summing corresponding subsystem values. Overall system reliabilities (VEH+ET+LRB) are computed by multiplying the results of Equation (16) by the ET reliability and the LRB reliability which is treated as a launch reliability.

Chapter IV

Analysis and Results

A. Preliminaries

Both Navy and Air Force aircraft were initially selected for deriving the parametric equations. However, Air Force subsystem data was utilized primarily in the current model because it was more comprehensive and consistent. Table 4 identifies the subsystems by military aircraft work unit code (WUC) and shows the mapping of WUC's to NASA's Work Breakdown Structure (WBS) for space vehicle subsystems and to the current Space Shuttle (STS) structure.

When a single WUC or STS Code mapped into two or more WBS codes, maintenance action rates (and therefore MTBM's) were prorated to the subsystems based upon percentages derived from the subsystem weights. The exception occurs in the propulsion system where the same aircraft equation (WUC 23) was used for the main, RCS, and OMS propulsion systems.

B. Regression Analysis

Multiple linear regression procedures were used to develop each of the parametric equations. A "best fit" was defined as the simplest mathematical model having a significant F value, a large R-squared value, and a small standard error. Generally, only independent variables which were significant (based upon a t-test) were included in the final model. Several models were marginally significant but retained nevertheless. A secondary criterion for model selection was the practical test that the model would provide reasonable results over the anticipated range of independent variable values. Because of the difference between aircraft and space vehicle parameters, extrapolations outside the domain of the input data were expected. Nonlinear transformations of the independent variables were also included in the model if they significantly contributed to the prediction power of the equation. Generally these transformations consisted of squaring, taking logarithms or square roots of the variables.

An investigation of the residuals would, on occasion, identify one or more data points as outliers (two or more standard deviations from the mean). At times these outliers were deleted from the data base. This was based upon the strong possibility that the AFALDP 800-4 data was incomplete. This is particularly true for the Vol VI data which contains a warning to this effect. In processing AFM 66-1, the monthly tapes from the bases may not contain all of the failures logged for that month. On the other hand, the monthly flying hours and sorties reported through a different data system is almost always complete. The net result is an overstatement of the MTBF. This was normally the case when outliers were observed.

As a result of the new WBS, additional regression analysis was performed. The original equations are documented in Appendices J-O of the first year report [23] and the new equations are documented in Appendix A of this report.

C. Analysis of Weights and Secondary Variables

Several variables were identified as primary or "driver" variables. These include (1) vehicle dry weight in pounds, (2) the sum of the vehicle length and wing span in feet, (3) crew size, (4) number of passengers, and (5) number of main engines. Values for these independent variables were based upon references [8] and [13] and are found in Appendix G of the first year final report [23]. Using these driver variables, regression equations were derived to estimate subsystem weights and secondary variables. Table 6 displays the weight equations and Table 7 displays the secondary variable equations. As a conceptual vehicle becomes better defined, it is expected values for these variables will be obtained from the design specifications and will not need to be estimated from the "driver" variables. With the exception of Prime Power (WBS 9) and Avionics (13), there are excellent least-squares fits to the data. The number of aircraft in the data base having an APU is quite small and its weight is not as dependent with vehicle size as are other subsystems. Avionics weight is not as highly correlated with vehicle size as are the remaining subsystems. Observe that the secondary variable equations must be evaluated in a particular order since several of these equations require values derived from the previous secondary variable equations. Correlation of these equations vary from under 60 percent to over 99 percent.

Table 5 Subsystem Weight Equations[5]

WBS	SUBSYSTEM	EQUATION	R
1.00	WING	$WT = -4485026.7 + 1351022\,LOG(DRY\ WT) - 135432[LOG(DRY\ WT)]^2 + 4522.4[LOG(DRY\ WT)]^3$	.980
2.00	TAIL	$WT = -290909.9 + 91929.4\,LOG(DRY\ WT) - 9709.9[LOG(DRY\ WT)]^2 + 343.5[LOG(DRY\ WT)]^3$	.960
3.00	BODY	$WT = 3.971E08 + 1.4180E06\,LOG(DRY\ WT) - 4.047E07/\sqrt{LOG(DRY\ WT)} - 12993808.8\sqrt{LOG(DRY\ WT)}$	.986
5.00	LANDING GEAR	$WT = -49535 + 0.28256(DRY\ WT) + 6873.7\,LOG(DRY\ WT) - 160.1\sqrt{DRY\ WT}$	.989

Because the weight equations are generated from aircraft data, they may not reflect the distribution of the subsystem weights in a space vehicle. Therefore, alternative estimators for subsystem weights are based upon NASA weight statements pertaining to two different proposed space vehicles (large and small) and the space shuttle. These weight distributions provide initial estimates only and should be revised and updated by the analyst. These percentages are then applied to the primary driver variable - vehicle dry weight to obtain the subsystem weights.

Table 7 Weight Distributions

D. MTBM Equations

Based upon the "driver" variables, subsystem weights, and the secondary variables, regression equations were derived to estimate MTBM. These equations are summarized in the following table with the regression analysis provided in Appendix J of the first year final report and Appendix A of this report. The estimated MTBM represents an unadjusted number and reflects aircraft reliability as captured in the data base. With the exception of Propulsion (WBS 1.6-1.8), acceptable correlations were obtained with the regression models. Aircraft engine failures were estimated exclusively from engine weight in order to utilize the equation for each Propulsion WBS and to provide a reasonable approach for extrapolating aircraft engine results to space vehicle propulsion systems. It is expected that this equation will be replaced as data on space propulsion systems becomes available. Because of the small sample size, WBS 9.20, Power, Battery, WBS 13.40, Avionics, Displays and Controls, and WBS 13.60, Avionics, Data Processing, MTBM's were estimated directly from the data rather than fitting parameters.

Table 8
MTBM Equations

WBS	SUBSYSTEM	EQUATION	Range	R

16 (.4/.5/.6)		Not Available		

The estimated MTBM is adjusted for technological change. In deriving the adjustment factor, a learning curve of the form given by Equation (2) is determined by using least-squares. These curves are summarized by subsystem in Table 9. Three separate equations were derived using historical data from the F-16B, B-1, and F-15A. Table 10 depicts the average growth rate (b parameter) for each subsystem. Only statistically significant growth rates from among the three aircraft were averaged. A separate analysis was performed for the overall aircraft.

Table 9

Using the methodology discussed in the previous chapter, technology adjustment factors were then derived. These factors, displayed in Table 10, represent an average annual growth rate based upon a compound growth curve. One subsystem, electrical, resulted in a negative growth rate which was set equal to zero. A combined avionics growth rate of .42 appeared to be excessive and was replaced with an adjusted rate obtained by deleting the F-4E - F-16A comparison which had a 0.22 annual growth rate. The rates shown in Table 10 represent the default values used in the implementation phase. In implementation, the TPS subsystem defaulted to the structural subsystems (WBS 1.00, 2.00, 3.00) growth rates. The APU growth rate was not computed because of insufficient data. The aircraft rate is used as a default value for those subsystems not computed explicitly from the aircraft data.

Regression equations for subsystem critical failure rates were derived from MODAS obtained aircraft air/ground abort rates found in Appendix N of the first year report [23] and are displayed in Table 11. Averages were used when the number of data points were insufficient to properly fit a regression curve. Because of the processing time required to obtain the abort rates, these equations are based upon a smaller sample size consisting of 13 aircraft. Each subsystem and each aircraft data point had to be retrieved separately from the MODAS ABORT SUMMARY REPORT. In general, there is a high correlation between vehicle size as measured by DRY WEIGHT or LENGTH plus WING SPAN and abort rates.

E. MHMA Equations

Predicted maintenance manhours per maintenance action were obtained from regression equations using primary, secondary and subsystem weight variables. These equations are presented in Table 12.

Marginal correlations were obtained for several subsystems including electrical, and oxygen subsystems. For those subsystems average manhours per maintenance action remains somewhat constant across aircraft. However, except for landing gear and oxygen, the fitted equations were significant at the 10 percent level and therefore partly explain the variation found in this parameter. In order to separate the on and off vehicle work being performed, the percent of off-equipment (POFF) manhours was also estimated from regression equations. These equations are identified in Table 13.

F. Scheduled Maintenance

Limited data is maintained on military aircraft pertaining to scheduled maintenance. These tasks fall into two categories: preflight/postflight inspections and periodic maintenance. For AF aircraft, total maintenance manhours expended in both areas are recorded in AFALDP 800-4. Using this data pertaining to 27 different data points, a regression analysis was performed with the results summarized in Table 14. Scheduled maintenance manhours is predicted as a percent of the unscheduled on-aircraft maintenance manhours. Once total unscheduled maintenance is computed, then the predicted percentage is applied to obtain the total scheduled maintenance.

Table 14
Scheduled Maintenance Manhours

As a percentage of UNSCHEDULED on-vehicle Maintenance Manhours:

$$\%UNSCH = 23.924 - .0545(LEN+WING) - 10.563\,LOG(LEN+WING) + 3.039\sqrt{LEN+WING}$$
$$.0215(FUS\,WT/FUS\,VOL) + 6.72e\text{-}5(FUSAREA)$$

(R = 0.81) (RANGE=.132, .794)

SCH MANHOURS = %SCH x UNSCH ON-VEHICLE MANHOURS

G. Removal Rates

Removal rates were based on data pertaining to six aircraft: C-5A, C-130E, C-141B, F-15D, F-111A, and T-38A. Since it was not possible to obtain adequate least-square fits for several WBS's, mean values were used. Results are depicted in Table 15.

H. Crew Sizes

Average (mean) crew sizes for performing unscheduled maintenance are predicted from derived regression equations. The input data for this analysis was obtained from the MODAS maintenance summary reports which provided by aircraft and by subsystem total maintenance manhours and total elapsed time. The raw data may be found in Appendix O of the first year report [23] and is summarized in Table 16. By dividing the maintenance manhours by elapsed time, an average crew size was obtained. For this analysis, crew sizes were estimated at the one digit (or higher) level. Because of the difficulty and time in extracting this data from MODAS, the data was obtained at the higher level. The resulting equations are in Table 17. No significant fit could be obtained for WUC's 2XXXX and avionics (5XXXX, 6XXXX and 7XXXX). Therefore mean values were used. Neither propulsion repair crew size nor avionics repair crew size seem to be related to aircraft size.

Table 16

I. Shuttle Parameters

Shuttle R&M data were obtained from the Martin-Marietta study. Subsystem MTBM's were derived from this data by summing the total number of reported subsystem maintenance actions across all 16 STS's and dividing the total into the total number of operating hours recorded against the subsystem over the same mission (see Appendix B [22]). For those subsystems identified as having cyclical failures (i.e. per mission), mission hours were used in place in operating hours in order to obtain an MTBM in units of hours per maintenance action. This was necessary for consistency with the aircraft computed MTBM's. The only exception to this was the landing gear subsystem whose failures were assumed to be cyclical for both the aircraft and the shuttle computed values. Several shuttle subsystems including structures, main propulsion system, environmental control, and mechanism map into two or more design vehicle WBS'. The overall failure rate of these subsystems was prorated to the appropriate WBS using the relative WBS weights obtained from the shuttle weight distribution. That is, letting

W = total weight of STS subsystem having a failure rate of 1/MTBM, and

W_i = weight of the ith WBS (within the STS subsystem, then

$$MTBM_i = 1/\lambda$$

where

$$\lambda = (W_i/W)/MTBM$$

The shuttle MTBM values obtained in this manner are identified in Table 18, column one.

Table 18

Appendix C contains the shuttle repair data. MTTR values used in this study were obtained from averaging, by subsystem, two or more MTTR's computed in the Martin-Marietta study [22] employing several methods as options one, two, and three. These averages consisted of two to five data points per STS depending upon the subsystem. Obvious outliers were eliminated. If a subsystem mapped into two or more WBS's, then each WBS would be assigned to the same MTTR. The resulting values are shown in Table 18, column 2. Appendix D contains the external tank and Titan failure data used as default values in the computer model.

Shuttle removal rates were also determined from the data set by dividing the total number of removals across all STS's by the total number of maintenance actions. Common WBS's to a single shuttle subsystem were assigned a common removal rate. These values are displayed in Table 18, column 3.

CHAPTER V

Implementation

I. Introduction

This chapter describes the PC based model for evaluating the reliability and maintainability equations derived in the previous chapter. Because of the large number of equations to be evaluated and the large number of additional calculations, the only practical way to implement the results of this research is on a computer. This PC based model is completely menu driven with all parameters computed at the subsystem (WBS) level and then rolled up to reflect overall vehicle performance.

Flying hours between maintenance actions, maintenance manhours per maintenance action, critical failure (abort) rates, percent on/off vehicle hours, removal rates, and crew sizes are estimated using the multiple regression models derived from aircraft data. Lower bounds (and in some cases upper bounds) are set if the equations predict values outside the limits of the input data. In addition to predicting failures and repair manhours, estimates of mission reliability, spares support, manpower requirements, turn times and fleet size are also made.

The computer model is design to evaluate all 33 major subsystems as defined by the NASA work breakdown structure (WBS). Upon execution of the model, the user may elect to delete any number of these subsystems from the analysis. The user may redefine any of the 33 subsystems, thus allowing the addition of new subsystems. If the user elects to redefine any of the subsystems, new input values should be specified consistent with new subsystem. The existing regression equations will no longer be appropriate.

II. Execution

The model consists of an executable MS DOS file (RAM.EXE). Upon execution, the user will be asked to supply a vehicle/project name. Unless changed by the user, this name will also serve as the input/output file name (with a .DAT extension) if the user elects to save the input parameters. The program is menu driven with the main menu (Figure 2) providing the primary options available to the user.

Normally, the user would either read in an existing input file or go to the input parameter menu in order to define the input parameters and data for use in the current study. Once the input data is finalized, the user selects the "COMPUTE R&M PARAMETERS" from the main menu and then selects the "OUTPUT REPORT MENU" in order to display the results of the computations. At any time the user may save the current values of the entire input parameter/data set under the file name shown at the bottom the main menu. This name may also

be changed at any time from the main menu[1]. Selected output values may also be saved. However, this option will not be completely defined until the corresponding costing model has been completed.

III. Modes of Operation

The model operates in one of three modes: PRECONCEPTUAL, WEIGHT DRIVEN, and WEIGHT/VARIABLE DRIVEN. In the preconceptual mode, the user specifies values for 6 driver variables which are used, in turn, to compute secondary variables. The user will also specify a weight distribution to be used in allocating the vehicle total dry weight (a primary variable) to the subsystems. The resulting subsystem weights along with the primary and secondary variables are then used as independent variables in evaluating the parametric R&M equations during computation.In the weight driven mode, the user must specify the actual subsystem weights to be used in the computation. In the weight/variable driven mode, the secondary variables must also be specified. The current mode of operation is displayed at the bottom of the main menu. The default mode is PRECONCEPTUAL. The user may change the mode using the primary system parameter input menu. It is possible to switch modes while defining the input data. For example, while in the **weight-driven** mode, the program will automatically update the secondary variables from the primary variables and subsystem weights. The user may the switch to the **weight/variable-driven** mode in order to change one or more

[1] The data will be saved in the default (current) directory unless the file name specifies another drive, e.g. A:TESTDATA.DAT. Subdirectories cannot be referenced in this manner.

of the secondary variables. The user should then stay in this mode for further computations in order to avoid having all the secondary variables recomputed.

IV. INPUT PARAMETERS

The input parameter menu is selected from the main menu and is shown below.

```

```

Figure 3 Input Parameter Menu

In establishing input values as part of a new study, the user would normally begin by identifying from among the 33 subsystems, those subsystems to be used. This option will also allow the user to change a subsystem name thereby permitting new subsystems to be added as long as the total number of subsystems does not exceed 33. Through the use of the "SELECT SHUTTLE/AIRCRAFT" menu, the user may bypass the aircraft generated parametric equations and use shuttle (or user input) MTBM & MTTR values. Shuttle values should be selected if a new subsystem has been defined since the parametric equations associated with old subsystem would no longer be valid.

By selecting "UPDATE/DISPLAY PRIMARY SYSTEM PARAMETERS," the user can assign values to the 6 primary variables and the 15 system parameters (shown below with their default values). Several of the system parameter values require additional description. "Adjust shuttle MTBM - Space" determines whether the shuttle selected MTBM value will have the environmental adjustment described in Chapter III, paragraph B (2) made. Since the shuttle MTBM values already account for launch and space operations, this adjustment should not be necessary. However, if the user inputs a new MTBM, which is not based upon the space environment, then the adjustment may be necessary. "Technology year" is used to determine the number of years of reliability growth at the rate specified on a corresponding menu.

Figure 4 Update/Display Primary System Parameters (Screen 2)

"Default abort rate" is used for those subsystems not addressed by abort rate equations and is also used for the ET and LRB systems. The user may specify abort rates by subsystem using a subsequent menu.The "Weibull shape parameter and launch factor" are the b and k values used in Equation 10 of Chapter III. "Available manhours per month" is the total number of hours during a month an individual is available within the workplace to do both direct and indirect work. Direct work is defined as the maintenance work addressed by the model while indirect work is all other categories of work. "Spares fill rate objective" is the percent of time a spare component is available when a failure has occurred. Selecting a "yes" response for "aggregate avionics" will result in a single avionics subsystem replacing the six different avionic subsystems available.

When selecting "subsystem weights" in the preconceptual mode, a secondary input menu is obtained allowing for the selection of one of four weight distributions as shown.

```
          SELECT WEIGHT DISTRIBUTION
      1 - LARGE VEHICLE DISTR
      2 - SHUTTLE WGT DISTR
      3 - SMALL VEHICLE DISTR
      4-  AIRCRAFT WGT DISTR
      RETURN - MAINTAIN CURRENT DISTRIBUTION

SELECT DISTRIBUTION....?
```

Figure 5 Select Weight Distribution

After selecting a weight distribution, the user may modify the percents as long they continue to add to 100 percent. These percentages are then applied to the total dry weight,and a subsystem weight display screen is then observed. In the other two modes, the subsystem weight screen is displayed directly allowing the user to change any subsystem weight. The primary variable vehicle dry weight will then be updated to reflect the sum of the subsystem weights. In the weight driven and weight/variable driven modes, total vehicle dry weight cannot be specified. Instead, this variable is computed from the sum of the subsystem weights. While in the weight driven or weight/variable driven mode, all subsystem weights may be adjusted by a common factor. The effect of subsequent usages of this factor is cummulative, since the original weights are not retained. However, by multiplying by the reciprical of the product of the factors used, the original weights can be recovered. The user must record the multiplying factors, since only the last factor is retained.

The secondary variable screen cannot be updated/changed in the preconceptual and weight-driven mode. In the weight/variable driven mode, the user may change any of the variable values. This screen is shown below:

ENTER RETURN...?

Figure 6 Secondary Independent Variables

The following menu is obtained when selecting "UPDATE/DISPLAY COMPUTATION FACTORS. The six different screens available from this menu allows the user to display or change, by subsystem, any of these input factors. Whenever a critical failure rate, removal rate, crew size, or percent off-equipment is updated by the user, a flag is set to ensure those values are no longer computed by the model. The user, however, may overide this condition when a computation is performed (see Figure 12). The MTBM/MTTR calibration screens allow the user to make subsystem changes to the unadjusted MTBM and MTTR by multiplying subsystem values by a common factor. This is particularly useful, for example in performing sensitivity analyses where the reliability and maintainability are systematically changed.

```

ENTER NUMBER TO BE CHANGED OR 0 IF NONE?
DO YOU WISH TO UPDATE SUBSYS OPERATING TIMES Y/N?
```

Figure 8 Update/Display Mission Profile

Beginning at launch time (t=0), times are cummulative. Pad time may include integration time and represent system operating hour times leading to a launch. The ground/recovery/processing time, on the other hand, accounts for subsystem operating hours which will not directly impact on the launch reliability. This screen may then be used to update the subsystem operating hours screen. At this point the user may then change selected subsystem operating hour profiles. Since the landing gear subsystem has failures per mission (on reentry), no update of this subsystem is possible. The main engines operate only in the ground and launch phases therefore the other phases will normally show zero values.

Figure 9 Update/Display System Operating Hours (Screen 1)

The "subsystem redundancy" configuration may be displayed and updated. Any number of parallel subsystems may be indicated on this screen, however, the default value is a single subsystem. For the power, engine, and avionic subsystems, a more general k-out-of-n redundancy may be specified. The minimum number of subsystems required for operation cannot exceed the number of redundant systems.

The user has the option of including either a liquid rocket booster (LRB) or an external fuel tank (ET) system or both in the analysis. These two input screens will display default values for the MTBM, MTTR, CRIT FAIL RT, CREW SIZE,and OPER HRS. These may be updated and then an R&M computation is performed by subsystem and rolled up to the system level. In addition, to the output displayed on these screens, system level output will be reflected on the summary performance report.

If these screens are not selected following initialization of the model, neither an LRB or ET will be included in the summary report. If these screens are selected and the user desires

Figure 11 Update/Display LRB/ET Reliability Data

Shuttle MTBM and MTTR values may be displayed and changed by subsystem. The default values are based upon the Martin-Marietta data. However, these values may be replaced with non-shuttle values. Therefore, the user has the option of inputting his own R&M parameters obtained from data collected on other aircraft or space systems.

The final input menu selection allows the scheduled maintenance percent (as a percent of the unscheduled on-vehicle maintenance manhours) to be changed. The default value is based upon the equation in Table 14, Chapter IV.

V. Computations

When selecting the "Compute R&M Parameters" from the main menu, the following menu is obtained:

```
                    COMPUTATION SELECTION MENU

                         FACTOR                     OPTION

               RETURN.....PROCEED WITH COMPUTATION...

ENTER NUMBER TO CHANGE?
```

Figure 12 Compute R&M Parameters

The user has the option of bypassing the parametric equations which would recompute new values for the factors on the above selection menu. This option would be exercised whenever it was desired to fix these values at their current level. This would normally be the case when the user sets these values from the corresponding input screens. The primary computation involves the recalculation of the MTBM and the MHMA factors. However, if the subsystem has been identified as "SHUTTLE", then the current MTBM and MTTR values from the shuttle input screens are utilized in the R&M analysis and the parametric equations are ignored. The remaining calculations are performed in accordance with the discussion in Chapter III. Anytime the user changes an input parameter, the full effect of this change on the output can only be guaranteed if a recomputation is performed. Remember, weights and secondary variables will be recomputed in the preconceptual mode and secondary variables recomputed in the weight driven mode.

VI. Output Reports

The output selection menu identifies six different output reports. Each report is displayed on the screen and consists of two or more pages (screens). Printed copy of the reports is obtained by doing a PRINT-SCREEN or CONTROL-PRINT-SCREEN (for continuous printing) to a parallel port printer. An example of each report is presented below followed by definitions of the column headings.

```

Figure 14 Reliability Report - page 1

CALIBRATED MTBM: The initial mean time between maintenance actions computed from the regression equations or in the case of "SHUTTLE" read in directly. Time is measured in flying hours except for the landing gear system which is measured in missions (or sorties). This value is then multiplied by the MTBM calibration factor (default is a factor of one).

TECH ADJ: The calibrated MTBM multiplied by the technology growth factor (Eq. 7).

SPACE ADJ: The technology adjusted MTBM recomputed to account for the increase in failure rates during launch and the decrease in failure rates while in orbit. "SHUTTLE"MTBM's do not have the space adjustment unless requested by the user (Eq. 11).

CRITICAL FAIL RATE: The percent of maintenance actions resulting in a ground or mission abort. This value is either computed from regression equations or input directly by the user.

CRITICAL MTBM: The mean time between critical maintenance actions computed from the space adjusted MTBM and the critical failure rate (Eq. 12).

SUBSYS NON-REDUNDANT MSN REL: The probability the subsystem/mission will be completed without a critical failure assuming no subsystem redundancy is present (primary system operates).

Figure 20 Manpower Report

MANHRS/MSN: Average maintenance manhours per mission computed as described in the maintainability report.

MANHRS/MO: The average maintenance manhours per month. The average maintenance manhours per mission multiplied by the required number of missions per month.

PERSONNEL BASED UPON MANHRS: The number of maintenance personnel required to support the subsystem average manhours per month requirement. Computed using a monthly manhour availability and the percent of indirect work factor (Eq. 23).

PERSONNEL BASED UPON MIN CREW: The average crew size for the subsystem computed from regression equations or input directly by the user.

Figure 21 Subsystem Spares Report

REMOVAL RATE/MA: The percent of maintenance actions which results in a component removal. The assumption is made that a component removal will generate a demand for a replacement (spare) component. The rate is computed from regression equations or input directly by the user.

MEAN DEMAND PER MISSION: The average number of removals (demands for spare components) per mission. Computed by multiplying the removal rate times the average number of maintenance actions per mission (see Maintainability report). This becomes the mean (number of demands) of the Poisson probability distrbution (Eq. 24).

SPARES REQUIREMENT: The expected number of spare components required per mission in order to achieve a specified fill rate. Fill rate is the percent of time a demand for a component is filled (Eq. 25).

EFFECTIVE FILL RATE: The actual fill rate achieved by the spares requirement. Differs from the fill rate goal as a result of the spares requirement having integer values.

Figure 22 Vehicle Turn Time Report - page 1

ON-VEHICLE MTTR (HRS): The on-vehicle mean time to repair measured in hours. Represents the average on-vehicle unscheduled repair time per maintenance action for a subsystem. Computed by dividing the manhours per maintenance action by the average crew size and multiplying by one minus the percent of off-vehicle work. In the case of the "SHUTTLE," input directly by the user (Eq. 26).

TOT MAINT ACT: The average number of maintenance actions per mission (see maintainability report).

NBR CREWS ASSIGNED: The number of maintenance crews (each equal to average crew size) available to perform parallel subsystem maintenance tasks on the vehicle.

AVG SUBSYS REPAIR TIME PER MSN: The average on-vehicle subsystem unscheduled maintenance time per mission. Computed by multiplying the on-vehicle MTTR by the average number of maintenance actions per mission and dividing by the number of crews assigned (Eq. 27).

The maximum average subsystem repair time will be highlighted, since it represents a minimum processing time.

Figure 28 System Performance Report - page 3

MANPOWER/SPARES REPORT: Shows total number of spares computed to support all vehicle subsystems. Displays manpower requirements for vehicle, ET (optional), and LRB (optional) computed in three ways:

MANHR DRIVEN AGGREGATE: Total manpower earned as a result of the total manhours of work generated in each category. Number are rounded up to the nearest integer. This method assumes complete centralization and versatility of the work force.

MANHR DRIVEN BY SUBSYS: Total manpower earned as a result of the total manhours of work generated by each subsystem. Number are rounded up to the nearest integer within each subsystem. This method assumes specialization in that each subsystem "earns" its own manpower.

CREW SIZE BY SUBSYS: Total manpower earned by assigning an average crew size to each subsystem.

TOT CREW BY SUBSYS: Total manpower earned by each subsystem by assigning an average crew size multiplied by the number of assigned crews. This number supports the minimum turn time calculations.

VEHICLE TURN TIMES: A summary of the minimum and maximum vehicle turn times in days is displayed for one, two and three shift maintenance. The average number of missions completed per month per vehicle and the required fleet size to support the target number of missions per month are also presented.

VI. User Options

At the conclusion of a run, the user has the option of repeating the analysis after changing one or more of the input parameters. Regardless of the mode, the primary variable screen may be displayed for update. If in mode 2 or 3, the subsystem weight screen will be available for update, and if in mode 3, the secondary variable update screen will also be available. The user may also save all of the current input data/paramerers for use at a later time.

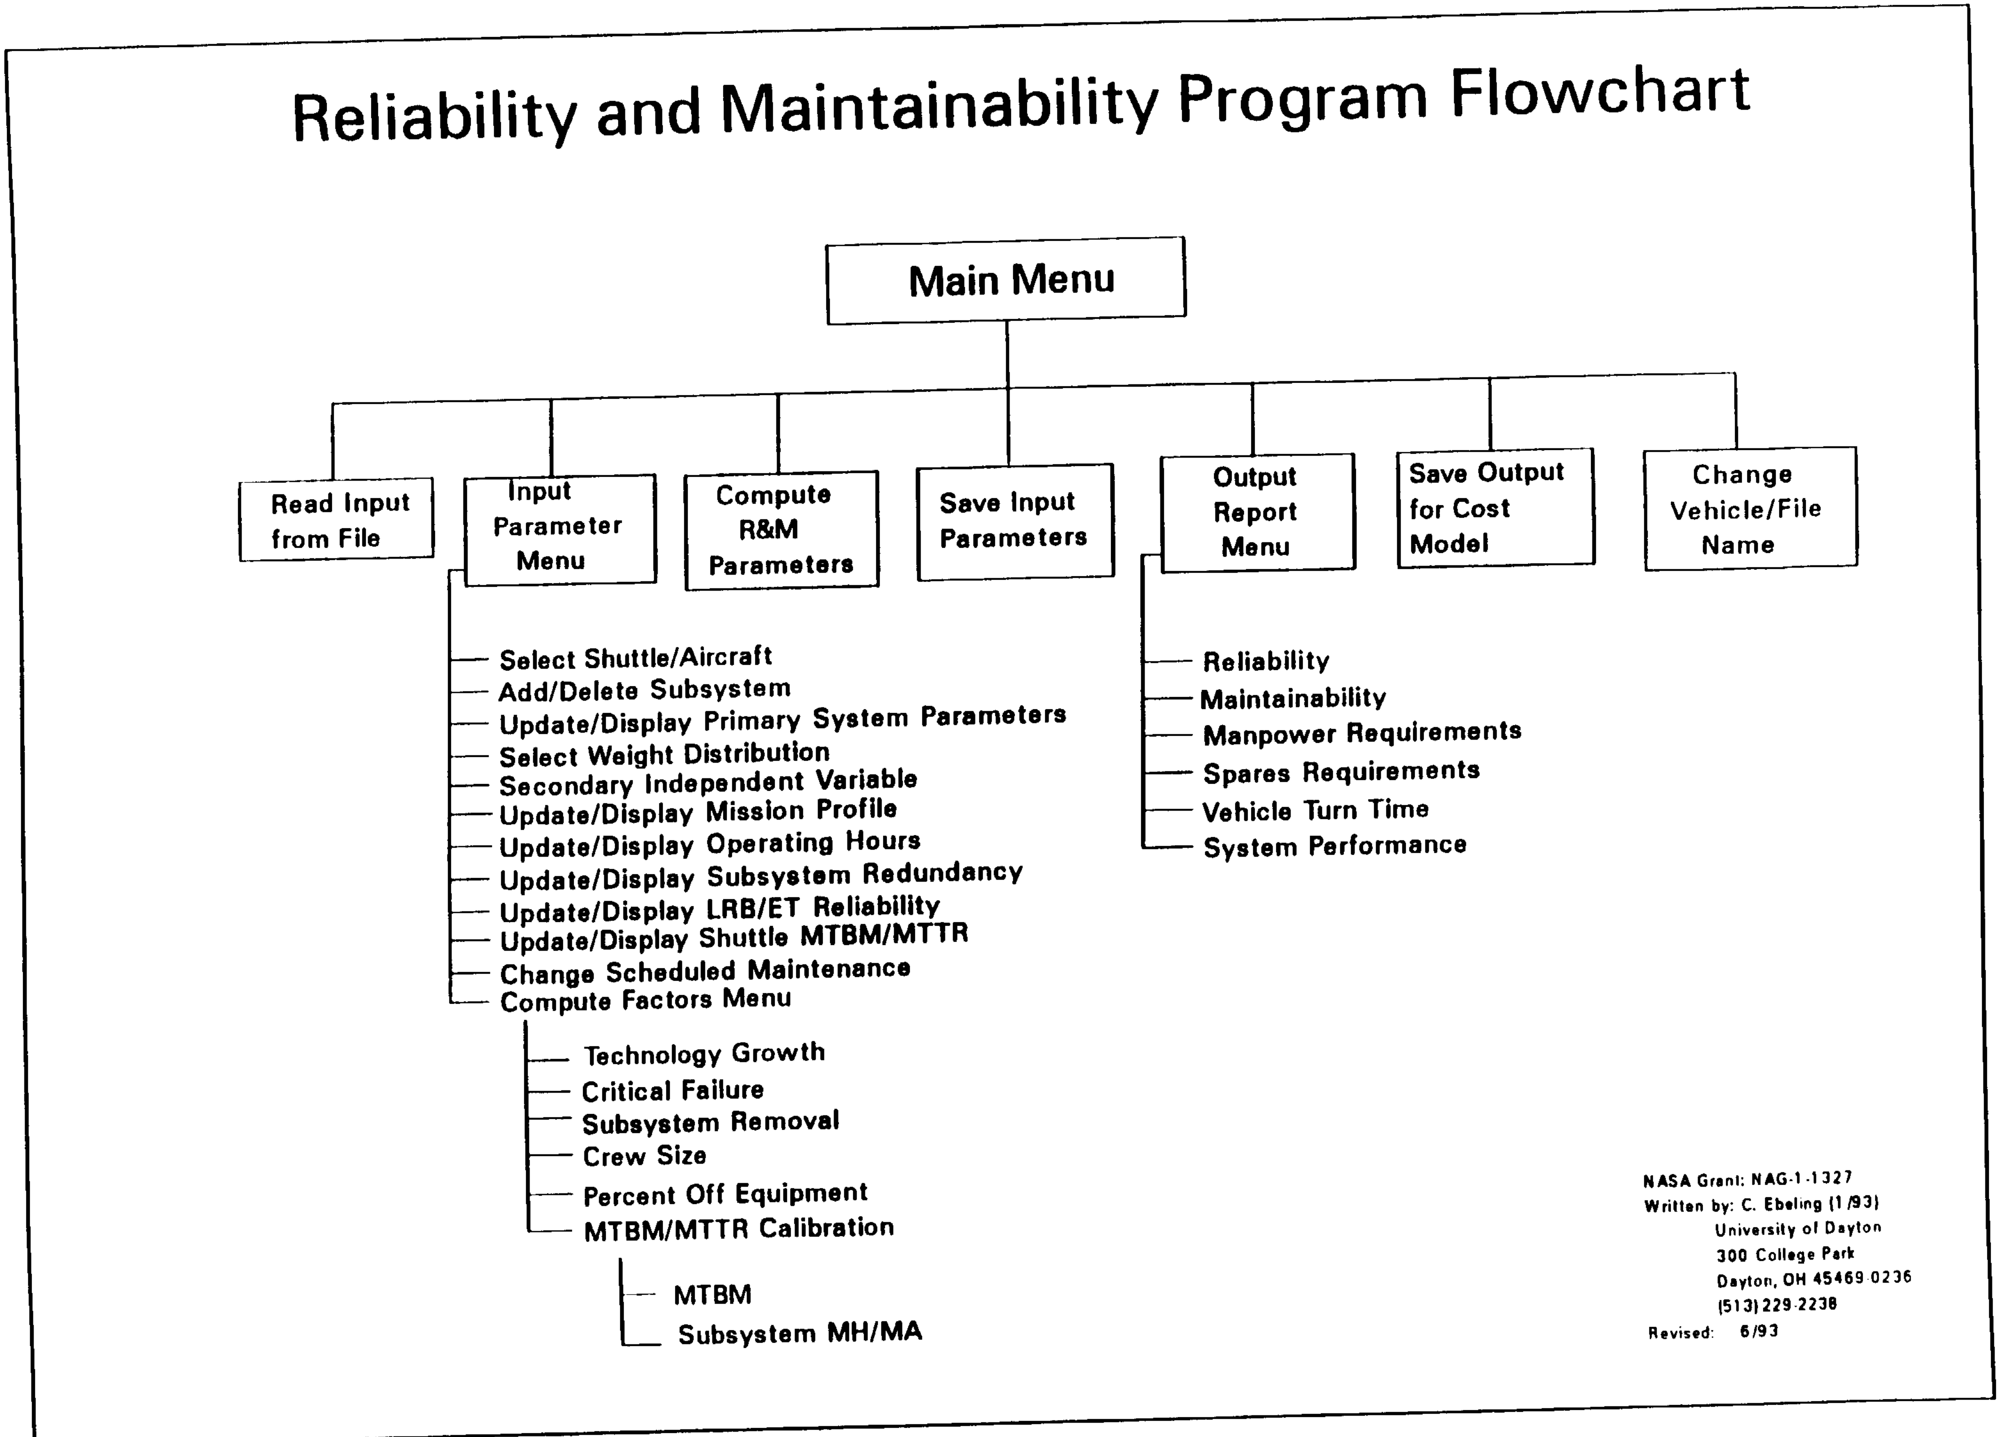

Figure 30 Reliability and Maintainability Program Flowchart

Chapter VI
Validation and Conclusion

I. Validation

Model validation was accomplished by running the computer model for different aircraft having known R&M parameters. The R&M parameters were obtained from AFALDP 800-4 Volume VI, and therefore, were not part of the input data to the model. Since the average date of the data in Volume IV is 1988, this date was used for the technology year. The space adjusted feature of the model was not utilized since it obviously does not apply to aircraft. Mission profiles reflected the average mission length of the aircraft.

Table 19 and 20 compare the predicted MTBM with the actual values for the F-16 and C-141B respectively. All three computational modes were utilized in this comparison. Two different time periods were compared in order to measure the variability in the actual data. In addition, a similar comparison is made for the F-4E (Table 21) in the preconceptual mode and the B-52G (Table 22) in the weight and variables driven mode. For the latter two comparisons, both the unadjusted and the technology adjusted MTBM's are presented. In general, it would appear that the predicted mean time between maintenance actions are in general agreement with the observed values. A further analysis was performed using the F-4E to validate the manhour per maintenance action parameters determined from the model (Table 23).

II. Conclusion

This report describes the data, methodology, results,and implementation of a two year research effort to develop a model for predicting R&M parameters for conceptual space transportation systems for use in determining operational capabilities and support costs. The final model incorporates both aircraft and Space Shuttle data. Considerable flexibility, on the part of the user, is provided by the implementing computer program, in allowing modification of the existing data.

The model is dynamic and should be updated as new data becomes available. It is particularly important to continue to integrate the current aircraft data base with data obtained from the Shuttle and other space systems. Subsystems unique to a space vehicle such as the TPS, propulsion systems, and docking systems require data not available from aircraft. Although this study has included these subsystems additional data obtained from other space shuttle missions is needed in order to insure a higher degree of accuracy. As the model is used over time, those features which seem to work should be retained while those which do not provide reasonable results should be replaced. The model is modularized in the sense that any regression equation may be easily replaced without affecting other areas of the model.

This research has provided an initial data base, a basic approach and a modeling structure for performing a reliability and maintainability analysis during the conceptual design activity. Based upon the validation effort, the model provides reasonable estimates (within the range of the data) and should be utilized with some degree of confidence. Data measuring the failure and repair process of space systems remains limited and the model has inherited this limitation. Nevertheless, it is empirically based and provides a rational means of obtaining support requirements and operational capabilities of space transportation systems prior to their development. –

Appendix E

Independent Variables

INDEPENDENT VARIABLE

Variable Name	Definition
DRY WGT	Empty weight (without fuel) of vehicle in pounds.
LEN+WING	Aircraft length plus wing span in feet.
WET AREA	Total external surface area of vehicle in square feet.
FUS VOL	Total volume of fuselage incubic feet excluding any engine inlet duct volume.
FUS AREA	External area of fuselage in square feet including canopy.
CREW SIZE	Total number of crew members.
NBR PASSENGERS	Maximum number of passengers.
ENGINES	Number of primary engines.
MSN LENGTH	Mission length in hours. May be adjusted by subsystem.
SUB WGTS	Total subsystem weight in pounds.
WHEELS	Total number of wheels.
ACTUATORS	Total number of actuators to operate all vehicle movable flight surfaces.
CONT SUR	Total number of control surfaces - ailerons, rudders, elevator tabs, flaps, spoilers and slats.
ECS WGT	Total weight in pounds of the environmental control system including heating, cooling and anti-icing equipment.
KVA MAX	Total electrical power output of engines, motors and APU driven generators/alternators in KVA.
SUBSYS	Total number of aircraft subsystems requiring use of hydraulic or pneumatic power.

FUEL TK	Number of separate internal fuel cells, bladders and tanks.
AV WGT	Weight in pounds of avionics equipment uninstalled (does not include wiring, shelves, ducts, fasteners).
TOT SUBS	Total number of avionics (AN nomenclature) subsystems.
AV INSTA	Weight in pounds of brackets, shelves, wiring and plugs used on avionics equipment.
DIF SUBS	Total number of different avionics subsystems (two or more identical units count as one).
BTU COOL	Total cooling capacity of air conditioning equipment used for personnel and equipment cooling. Measured in BTU/HR/1000.
