VI.	IUE IMAGES USED IN THE ATLAS	395
VII.	ERRATA	421

I. INTRODUCTION

Since its launch on 26 January 1978, the *International Ultraviolet Explorer (IUE)* Satellite has been extensively utilized by astronomers worldwide. A large number of ultraviolet spectra have been obtained with the *IUE* to carry out a wide range of research programs. These spectra reside in the *IUE* archive. And this *IUE Ultraviolet Spectral Atlas of Selected Astronomical Objects* (or the *Atlas*) is based on the spectra which were available in the archive in 1985-1986 when we did most of the data reduction and merging (see §II).

In 1983, we published the *IUE Ultraviolet Spectral Atlas* (Wu *et al.* 1983) for "normal stars" which have good MK spectral types (see Morgan and Keenan 1973). The 1983 *Atlas* and its future additions are intended to serve as a standard reference library for stellar ultraviolet spectra. Therefore, a substantial amount of observing time and effort have been devoted to obtain spectra of uniform high quality. Almost all the spectra in the 1983 *Atlas* and those obtained in its augmentation programs are trailed or pseudo-trailed (3 or 4 exposures taken in the same image by placing the star at discrete points along the major axis of the large aperture which is perpendicular to the dispersion direction). Unfortunately, it is not feasible to have such high quality spectra for the present *Atlas* because many of the objects are rather faint for *IUE* spectrographs. In fact, an appreciable number of spectra presented in the *Atlas* are of low signal-to-noise ratio (S/N). This *Atlas* was intended to be totally an archival project, no observing time was requested from the *IUE* Observatory for enhancing the S/N of faint objects or to increase the sample of objects. The data have not been reprocessed with the same *IUE* pipeline image processing software, because the reprocessing of such a large number of images would put too heavy a demand on the *IUE* Observatory. However, as discussed in §II, considerable care had been devoted in the reduction and merging of the data in order to derive the fluxes presented in this *Atlas*.

The *Atlas* is intended to serve as a quick reference for the ultraviolet spectra of many categories of astronomical objects. While the 1983 *IUE Ultraviolet Spectral Atlas* (Wu *et al.* 1983) emphasizes the photosphere of "normal, single and non-variable" stars which are on the main sequence or have evolved to be subgiants, giants, bright giants and supergiants; the present *Atlas* attempts to fill in other areas of the Hertzsprung-Russell diagram. For example, pre-main sequence stars, chemically peculiar stars, pulsating variables, subluminescent stars and Wolf-Rayet stars are included. The *Atlas* also shows reflected sunlight from planets and asteroids and emission from comets; the chromospheric and transition region emission from late type stars; composite spectra of stars, gas streams, accretion disks and gas envelopes from binary systems; the behavior of gas ejecta shortly after the outburst of supernovae; and several kinds of nebulae: H II regions and planetary nebulae with gas emission plus star light, and supernova remnants with shock heated gas. The

Atlas provides several components which may be needed for population synthesis studies of composite stellar systems: subluminescent stars, H II regions like NGC 604, luminous stars, population II stars and globular clusters. The luminous stars in the Magellanic Clouds are included because, it may be more appropriate to compare the OB stars in dwarf irregulars, luminous blue galaxies, and some starburst galaxies with those in the LMC and SMC rather than the galactic OB stars in the 1983 *Atlas* (Wu *et al.* 1983). Finally, the *Atlas* presents the ultraviolet spectra of a wide range of extragalactic objects. They include normal galaxies of different Hubble types, and active galaxies such as Seyfert galaxies, broad-line radio galaxies, BL Lacertae objects, and quasi-stellar objects.

The *IUE* scientific instruments are described in Boggess *et al.* (1978a). Further studies and calibrations of the instruments are presented in the volumes of the *NASA IUE Newsletter* and *ESA IUE Newsletter* published by the *IUE* Observatories at NASA Goddard Space Flight Center and ESA VILSPA Station, respectively. The results of many important *Newsletter* articles are referenced in Harris and Sonneborn (1987), Sonneborn *et al.* (1987), and Grady and Taylor (1989). The data for the 1150-1950Å region were taken with the Short Wavelength Prime (SWP) camera and those in the 1950-3200Å range were obtained with the Long Wavelength Prime (LWP) or Redundant (LWR) cameras. However, for Seyfert Galaxies and QSOs, SWP data beyond 1950Å are used (see §IID). The spectral resolution for the *IUE* low dispersion data is about 6Å. The *IUE* data processing system and results are described in Boggess *et al.* (1978b) and Turnrose and Thompson (1984), more recent enhancements are summarized in Grady and Taylor (1989), and Harris and Sonneborn (1987). The capabilities of the *IUE* Regional Data Analysis Facility (RDAF) are described in the *IUE* Regional Data Analysis Facility User's Tutorial Manual prepared by the RDAF staff. In §II we discuss the interactive data reduction, merging, and calibration processes we adopted in the production of this *Atlas*, using the *IUE* RDAF at the Goddard Space Flight Center. Since the characteristics and capabilities of the *IUE* instruments, the pipeline data processing system and the RDAF have been discussed in detail in the above mentioned references, we will not repeat the discussions here.

In order to provide the readers with a quick reference of emission and absorption features commonly seen in the *IUE* low dispersion spectra, we compiled a list of emission lines in Table 1.1 and a list of absorption lines in Table 1.2. A more detailed emission line list can be found in Penston *et al.* (1983) which is based on *IUE* high dispersion spectra of the slow nova RR Telescopii. More complete lists of interstellar or intergalactic absorption lines are given in Blades *et al.* (1988), Morton, York, and Jenkins (1988), and Morton and Smith (1973). For discussion of the ultraviolet spectrum of various categories of astronomical objects, the readers should consult the appropriate review articles in Kondo (1987). Interstellar extinction plays a major role in ultraviolet astronomy. For convenience, the average extinction curve of Savage and Mathis (1979) is given in Table 1.3. The interstellar extinction curve can also be expressed analytically (Seaton 1979):

$$2.70 \leq 1/\lambda \leq 3.65 \quad A_\lambda/E(B-V) = 1.56 + 1.048/\lambda + 1.01/[(1/\lambda - 4.60)^2 + 0.280] \quad (1-1)$$

$$3.65 \leq 1/\lambda \leq 7.14 \quad A_\lambda/E(B-V) = 2.29 + 0.848/\lambda + 1.01/[(1/\lambda - 4.60)^2 + 0.280] \quad (1-2)$$

$$7.14 \leq 1/\lambda \leq 10 \quad A_\lambda/E(B-V) = 16.17 - 3.20/\lambda + 0.2975/\lambda^2 \quad (1-3)$$

where λ is in microns. Savage and Mathis (1979) and Seaton (1979) adopt $A_V/E(B-V) = 3.1$ and 3.2 respectively. However, in the UV, their curves are essentially the same, since they both are based on the same observed data. The shape of the extinction curve is determined by the properties of the dust particles which cause the extinction. Different physical environments can modify dust particles and produce widely varied extinction curves (see review by Mathis 1987).

Briefly summarizing the contents of this *Atlas*, in §II we discuss each step in reducing, merging, and calibrating the *IUE* data in order to arrive at the plots and binned fluxes presented in §V. In §III we list the individual objects which are included in the *Atlas*. The 1950 Right Ascension and Declination, V and B-V are presented in Table 3.1. The objects, organized in astronomical categories are given in Table 3.2 together with the identification of *IUE* images which are used in the *Atlas*. The reader should consult §VI for pertinent information on each image. In §III, we also briefly discuss the rationale for the selection of each category of objects. We acknowledge our colleagues who had provided valuable assistance in the course of preparing this publication in §IV. The atlas of spectral plots from 1150-3200Å, and tables of fluxes at 5Å bins are presented in §V. These are organized by plate numbers. Each plate generally contains a plot of two spectral scans and a table of 5Å binned fluxes for the two scans. The *IUE* images, ordered by their image number, which are used in the production of this *Atlas* are given in §VI. For each image, a subset of the information given in the Merged Log of *IUE* Observations is provided. The entries include exposure time and exposure level, and also the V magnitude derived from the *IUE* Fine Error Sensor (FES) counts observed shortly before the image was taken. The conversion from FES counts to V magnitude is based on the algorithm given in Imhoff and Wasatonic (1986).

Finally we wish to point out that in-depth reviews in areas related to most of the categories of this *Atlas* are given in *Exploring the Universe with the IUE Satellite* (Kondo 1987). We hope that this *Atlas* together with the Kondo (1987) volume, and the *IUE Ultraviolet Spectral Atlas* for normal stars (Wu *et al.* 1983 and its augmentation) will serve as useful tools in astronomical research and teaching.

TABLE 1.1

EMISSION LINES COMMONLY FOUND IN LOW DISPERSION IUE SPECTRA

Wavelength	Identification	Where Found
1176	C III	Planetary Nebulae, Carbon Stars, Symbiotic Stars, Wolf-Rayet Stars
1199	S III	Solar System Objects
1216	H I (Lyman α)	Everywhere (and geocoronal)
1238, 1242	N V	Planetary Nebulae, Symbiotic Stars, Wolf-Rayet Stars, Cataclysmic Variables, Low Mass X-ray Binaries, Supernovae, Interacting Binaries, Novae, Seyfert Galaxies and QSOs
1247	C III	Symbiotic Stars, Wolf-Rayet Stars
1256	S II	Solar System Objects
1277-1281	C I	T Tauri Stars, Late Type Stars
1299	Si III]	Symbiotic Stars, Interacting Binaries
1304	O I	RS CVn Stars, Late Type Stars, Novae, Seyfert Galaxies and QSOs
1309	Si II	Planetary Nebulae
1334, 1335	C II	Planetary Nebulae, Late Type Stars, RS CVn Stars, Wolf-Rayet Stars, Cataclysmic Variables, Novae
1342	O IV	Carbon Stars, Symbiotic Stars, Wolf-Rayet Stars, Low Mass X-ray Binaries
1371	O V	Planetary Nebulae, Carbon Stars, Symbiotic Stars, Low Mass X-ray Binaries
1394, 1403	Si IV	Planetary Nebulae, Late Type Stars, RS CVn Stars, T Tauri Stars, Low Mass X-ray Binaries, Cataclysmic Variables, Interacting Binaries, Novae, Seyfert Galaxies and QSOs
1401	O IV]	Symbiotic Stars, Novae
1406	S IV	Solar System Objects, Novae
1459-1467	C I	T Tauri Stars
1473, 1485	S I	RS CVn Stars, Late Type Stars
1483, 1487	N IV]	Planetary Nebulae, Symbiotic Stars, Wolf-Rayet Stars, Novae
1548, 1550	C IV	Planetary Nebulae, Late Type Stars, Symbiotic Stars, Novae, Wolf-Rayet Stars, Cataclysmic Variables, Interacting Binaries, Low Mass X-ray Binaries, Seyfert Galaxies and QSOs, Emission Line Galaxies
1561	C I	Comets
1576	[Ne V]	Planetary Nebulae, Novae
1577	C III	Symbiotic Stars
1602	[Ne IV]	Planetary Nebulae, Novae, Symbiotic Stars
1640	He II	Planetary Nebulae, Late Type Stars, RS CVn Stars, Wolf-Rayet Stars, Low Mass X-ray Binaries, Seyfert Galaxies and QSOs
1641	O I	RS CVn Stars, Late Type Stars, Symbiotic Stars, Novae
1656	C I	RS CVn Stars, Late Type Stars
1657	C I	Comets
1658-1667	O III]	Planetary Nebulae, Wolf-Rayet Stars, Seyfert Galaxies and QSOs, Novae, Late Type Stars, H II Regions, Symbiotic Stars
1672	Al II	Interacting Binaries, Late Type Stars
1711	Si II	Planetary Nebulae, Wolf-Rayet Stars
1718	N IV	Planetary Nebulae, Wolf-Rayet Stars, Low Mass X-ray Binaries, Cataclysmic Variables, Novae
1729	S III]	Solar System Objects
1747-1754	N III]	Wolf-Rayet Stars, H II Regions, Novae, Supernovae
1760	C II	Planetary Nebulae
1808, 1817	Si II	Planetary Nebulae, RS CVn Stars, Late Type Stars
1815	[Ne III]	Planetary Nebulae, Novae
1856, 1863	Al III	Late Type Stars, Interacting Binaries
1882, 1892	Si III]	Planetary Nebulae, Late Type Stars, H II Regions, Supernovae, Novae, Seyfert Galaxies and QSOs
1900	S I	RS CVn Stars, Late Type Stars, Supernovae, H II Regions

II. DATA REDUCTION AND MERGING

This section describes how the final merged spectra were produced. Briefly, the steps involved were 1) removing blemishes from the individual spectra; 2) correcting early SWP images processed with the erroneous intensity transfer function (ITF); 3) extracting the individual spectra; 4) calibrating the extracted spectra; 5) correcting the calibrated spectra for various instrumental and observational effects (such as variations in camera sensitivity and use of small aperture fluxes); 6) checking the corrected spectra for artifacts, and in some cases, excluding or including data for special purposes, 7) aligning the spectra to be merged to a common wavelength scale, 8) and merging the individual spectra into final spectra to be plotted. The final fluxes were then averaged in 5Å bins to produce the flux tables. This procedure was followed in producing all of the merged spectra, excepting the Population II stars spectra. The merged spectra for the Population II stars were contributed by C. Cacciari, and details of the production of these spectra are given in Cacciari (1985).

All of the data reduction and merging processes were carried out at the *IUE* Regional Data Analysis Facility (RDAF) located at the Goddard Space Flight Center (GSFC). The software in the *IUE* RDAF is written in the Interactive Data Language (IDL). The IDL routines used were (in order of use) GETSREG, LBL, BSPOT, SWPFIX, MAKENOEPS, IUELO, LOW, LOWCOR, FIXEPS, FIXLOW, LOSHIFT (the GSFC RDAF version), and COADD. The various reduction steps are discussed in detail below.

A. REMOVING THE BLEMISHES

IUE data quality can be affected by a number of contaminating sources — cosmic-ray hits in the Ultraviolet-to-Visible Image Converter (UVC) of the cameras, "hot pixels" on the targets of the cameras, random bright spots due to radioactive decay of atoms in the UVC phosphor, and microphonic noise or "pings". The first step in the reduction was to remove as much of the contamination as possible, without spending an enormous amount of time at it.

IUESIPS has automatically flagged bright spots since 1982 October 19 at VILSPA and 1982 November 19 at GSFC. The flagging routine checks for high contrast "spikes" (more than 90 DN above local background) confined to a very limited area. In practice, however, the routine can miss many bright spots of lower contrast, as well as hits from grazing incidence cosmic rays whose effects are not so localized. The patterns left by cosmic-ray hits generally vary depending on the incident angle and energy of the incoming particle, and can affect many pixels. Very intense bright spots can also produce some lower level leakage into surrounding

pixels, and this leakage is also often missed by the flagging routine. Conversely, the flagging routine has at times flagged genuine bright emission lines as well as bright spots (Grady and Imhoff 1985).

For these reasons we did not attempt to develop an algorithm to identify blemishes automatically. Instead, we relied upon visual identification. We started with the spatially resolved, geometrically corrected line-by-line (LBL) or extended line-by-line (ELBL) file for each spectrum, and made plots of the cross-cut profile (*i.e.*, perpendicular to the dispersion direction) and pseudo 3-dimensional plots of the intensities (in linearized flux units). The cross-cut profile was used to determine the position and width of the region containing the spectrum. The pseudo 3-D plots were then compared with the photowrites, and searched for bright spots or other features which were not centered on the spectrum and/or did not follow the overall spatial profile of the spectrum. If two or more spectra (using the same camera) of a given object were reduced, then the photowrites were compared to identify blemishes which appeared in only one image.

In general, our criteria were more stringent near the edges of the spectrum, where blemishes were easier to identify. We also took more care near the long and short wavelength ends of images, especially those taken with the LWP, where multiplication by the inverse sensitivity curve would mean a large magnification. If there were any question as to whether an apparent feature were a real feature of the spectrum or not, then it was considered to be real. Hence some contaminating blemishes may still have been included, if these were broad, low contrast, or more or less centered on the spectrum.

Hits, bright spots, and other blemishes identified within the spectral region were flagged interactively by changing the corresponding epsilon values to $\text{EPS} = -325$. Hits outside the spectral region were not flagged, as the background is heavily smoothed before subtraction.

B. CORRECTING EARLY SWP ITF ERRORS

Early SWP images were affected by an error in the intensity transfer function (ITF) used for the photometric correction. Detailed descriptions of the error can be found in the discussions by Holm (1979), by Cassatella *et al.* (1980), and by Turnrose, Thompson, and Gass (1984), and in the GSFC RDAF User's Tutorial Manual (Version 5, November 1987, p. 34). The error in the ITF affected SWP images processed between 1978 May 22 and 1979 July 7 at GSFC, and between 1978 June 14 and 1979 August 7 at VILSPA. Images processed between these dates, which had not already been reprocessed using the correct ITF, were corrected using the routine SWPFI_X written by Cassatella *et al.* (1980). The correction was applied to the spatially resolved line-by-line files before the spectra were extracted. The extracted spectra could then be calibrated using the standard SWP sensitivity curve (Bohlin and Holm 1980). Cassatella *et al.* estimated that approximations in the correction affected the photometric accuracy of these images by less than 5%.

C. EXTRACTING THE INDIVIDUAL SPECTRA

The next step after identifying and flagging the blemishes in an image was to extract the one-dimensional flux spectrum. We used a modified version of a standard RDAF routine which allows users to create their own MELO files from the spatially resolved LBL files. The standard routine simply sums the linearized flux intensities for each wavelength pixel over the lines in the extraction region, and assigns an epsilon value to the flux sum which is the minimum epsilon value of all the lines for that pixel. In order to exclude blemishes and other bad data, we modified the standard routine to exclude all data flagged with EPS below -200, that is, data contaminated by blemishes (EPS=-325), data affected by reseau marks (EPS=-800), and saturated data (EPS=-1600). Good data (EPS=100) and extrapolated data (EPS=-200) were included with equal weight. The epsilons were still set to the minimum values, except in cases where data at a given wavelength were flagged only for blemishes and some of the pixels at that wavelength contained good or extrapolated data. In such cases the epsilons were set to 100.

Excluding data from the sum effectively meant that the intensity was set to zero before the addition. It was therefore necessary to apply a correction in order not to underestimate the fluxes. The correction was done as follows:

- 1) The background was summed over the lines in the background region, smoothed by being put once through a median filter and twice through a boxcar filter, and divided by the number of background lines. The widths of the filters (63 pixels for the median filter, 31 for the boxcar filter) were the same as the widths used for the smoothing in the standard RDAF routine.

- 2) At every wavelength, the strength of the source signal was estimated by subtracting the smoothed background from the smoothed total, or gross, signal at the center of the spectrum. The gross signal was smoothed in the same manner as the background.

- 3) A profile for the source signal was then generated (the background was assumed to be constant across the region). For point sources, Gaussian approximations to the instrumental point source responses were used. For widened spectra, or spectra of extended sources, sums of several displaced Gaussians were used. The point source Gaussian parameters, as well as the number of Gaussians to use for wider spectra and their relative displacements, were determined from fits to well-exposed spectra of various widths. In some cases, regions narrower than the nominal point source region were used (see §E below), and in these cases the single Gaussian profiles were simply truncated.

- 4) The intensity distribution across the extraction region was then modelled by the superposition of source profile and constant background terms having the appropriate relative strengths. The model was used to calculate the relative fraction of the gross signal contributed at each line.

5) During the addition, the gross signal in each line was then weighted by the relative fraction of the total signal contributed by that line, and normalized by the total number of lines. In effect, the intensity from each excluded pixel was replaced by the value expected using the model of the intensity distribution.

The smoothed background signal was then subtracted from the total, corrected signal to yield the net source fluxes. A standard format ESLO/MELO file was then created, in the same manner as in the standard RDAF routine.

The source profile assumed in the correction was automatically determined from the width of the extraction region. If the actual profile of the spectrum did not match the assumed profile, then errors in the correction could result, leading to pseudo-emission or absorption features. Accordingly, each extracted spectrum was carefully checked for the possible presence of such features. When found, such features were flagged by interactively setting $EPS = -600$ (see §F below). In general, the automatic profiles matched the actual profiles fairly well, and we did not find large numbers of artifacts. As expected, the most prominent artifacts tended to be found in spectra of bright targets with low background levels, and in spectra containing blemishes which covered many pixels.

D. ABSOLUTE CALIBRATION

The individual extracted spectra were then calibrated. Prior to the calibration, however, the ESLO/MELO files were converted to University of Colorado RDAF format files (having extension ".LOW"). The conversion was done in order to create header or history files (".HDR" extension) describing all the extraction procedures which had been done to the file. In this way, records of the extraction and subsequent processing could be kept automatically for each file. The conversion software resmoothed the background signals from the MELO files and recalculated the net fluxes from the gross and smoothed background signals, in the same manner as the GSFC RDAF routines.

The calibration of the net fluxes was done using the University of Colorado RDAF routine LOW. The net fluxes were multiplied by the inverse sensitivity curves, and divided by the exposure time in seconds. The inverse sensitivity curves were taken from the calibration of Bohlin and Holm (1980) for the LWR and SWP cameras, and from the calibration of Blades and Cassatella (1982) for the LWP camera. The absolute calibrations are probably accurate to $\pm 10\%$ (Bohlin *et al.* 1980; Blades and Cassatella 1982).

During the calibration, an option was chosen which automatically trimmed the SWP spectra to the range 1150-1950Å, and the LWR/LWP spectra to the range 1950-3350Å. The long wavelength spectra were later truncated at 3200Å. The LWR spectra were truncated because Holm's (1985) sensitivity degradation determination did not extend past 3200Å, and the LWP spectra were truncated to match those of the LWR. The long wavelength endpoint for the SWP spectra was chosen to avoid an artificial brightening at the edge

of the camera, which sometimes affects wavelengths as short as 1950Å. Unfortunately, for many active galaxies the important CIII] 1909Å emission lines are shifted to wavelengths between 1950Å and 1980Å. The SWP is more sensitive at its long wavelength end than either the LWR or LWP at their short wavelength ends, so that a truncation point of 1950Å is not desirable for these objects. We therefore truncated the SWP spectra for the Seyfert galaxies and QSOs (plates 148-152, 161-165) at the longest wavelengths which were not affected by camera edge effects.

After the calibration, the values of the epsilon flags were checked to ensure that all good data were flagged with EPS = 100. When necessary, the epsilon flags were changed to agree with this convention.

E. CORRECTIONS TO CALIBRATED SPECTRA

In addition to the correction of early SWP images for the bad ITF, which was applied to the line-by-line files, it was sometimes necessary to apply various corrections to the calibrated spectra. These were corrections for 1) short (less than one minute) exposure times, 2) actual aperture lengths, for trailed spectra, 3) variations in camera sensitivity, 4) use of small aperture spectra, and 5) use of narrowed extraction regions to avoid reseau marks. Special handling was also required for spectra of some of the Solar System objects.

i) Correction for Short Exposure Times

Actual exposure times for *IUE* images are quantized in units of on-board computer (OBC) "ticks", or units of 0.4096 seconds. The rise and fall of the detector's high voltage also causes a delay of 0.120 ± 0.015 seconds for each exposure (LWR, SWP Schiffer 1980; LWP Crenshaw 1986). Hence, actual exposure time is related to commanded exposure time by

$$t_a = \text{Int}(t_c / 0.4096) \times 0.4096 - 0.120 \quad (2-1)$$

where t_a and t_c are the actual and commanded exposure times in seconds, respectively, and Int stands for integer value. For a short exposure the actual exposure time can be significantly shorter than the commanded time. We therefore corrected all exposures with commanded times shorter than one minute to the actual exposure times. For exposures longer than one minute, the difference in times is always less than 1%. For most short exposures, the actual times were entered directly into the extraction routine. In some cases, however, the commanded times were entered, and these fluxes were subsequently renormalized using the actual exposure times.

ii) Correction of Trailed Exposure Times

As explained by Schiffer (1982a), the exposure times given in the science headers for trailed spectra are calculated from the trail rate and the number of passes through the aperture, assuming aperture sizes of

precisely 20 arc-seconds. However, the current best estimates for the length of a trail through the aperture are 20.5 arc-seconds and 21.4 arc-seconds for the long and short wavelength spectrographs, respectively (Panek 1982). We used these estimates to recalculate the exposure times for all of the trailed spectra. Usually, the correct exposure times were entered when the spectra were extracted. In a few cases, the exposure times were taken directly from the science headers, and the fluxes were subsequently renormalized using the correct aperture sizes.

iii) Correction for Variations in Camera Sensitivity

Sensitivity monitoring of a large number of spectra of calibration stars (Sonneborn and Garhart 1986, and references therein) has shown that the sensitivities of the *IUE* cameras are, to varying degrees, functions of both camera temperature and time. Multiple regression analysis of these data show that the sensitivities depend only weakly on temperature, and that the LWR camera shows the strongest dependence. The cameras have also shown some degradation in sensitivity with time, with the LWR camera again showing the largest effect.

At the time that we began reduction of the data for this *Atlas* (early 1985), the most current studies of camera sensitivity variations were those of Holm (1985) and Sonneborn (1984). Following these studies, we corrected the LWR fluxes to a reference camera head amplifier temperature (THDA) of 12 (Bohlin and Holm 1980), using the formula given by Imhoff (1986) with Sonneborn's (1984) coefficient of 0.81% decrease/°C. At worst, the corrections were always less than ~ 5%. For comparison, Sonneborn and Garhart (1986) give a coefficient of 0.70% decrease/°C. Temperature induced variations in the SWP and LWP sensitivities were smaller, and we judged them to be negligible.

We corrected the LWR fluxes to the nominal epoch of calibration, 1978.8, using the wavelength dependent degradation function determined by Holm (1985). This function differs slightly from the degradation correction determined by Clavel, Gilmozzi, and Prieto (1986), which the RDAFs have recently adopted as the standard degradation correction. We did not, however, correct the SWP or LWP fluxes for changes due to sensitivity degradation. As of early 1985, no measurable change in the SWP sensitivity had been reported for observations since early 1979, and the time dependence of the LWP had not yet been determined. Sonneborn and Garhart (1986) have presented a detailed discussion of changes in the SWP and LWP sensitivities; in general, since early 1979 the sensitivities at all wavelengths have varied by $\leq 1\%$ per year. Before early 1979, the SWP sensitivities at $\sim 1550\text{\AA}$ and $\sim 1850\text{\AA}$ decreased by $\sim 5\%$ and $\sim 10\%$, respectively (see Holm and Schiffer 1980, and figures in Schiffer 1982b, c).

Because Holm's (1985) determination of the LWR sensitivity degradation function did not extend past 3200Å, the routine which corrected for the degradation, LOWCOR, automatically truncated the LWR spectra at 3200Å. The LWP spectra were subsequently truncated to provide a uniform wavelength scale for the final plots.

iv) Correction for the Use of Small Aperture Spectra

Small aperture spectra were sometimes included for objects whose ultraviolet spectra show a wide dynamic range in intensity, such as objects having emission lines of high equivalent width, or objects whose UV continua fall very steeply. Examples of the first case are novae, symbiotic stars, and Wolf-Rayet stars, while Solar System objects and cool stars are examples of the latter. In such cases, optimum exposures of the brighter spectral regions require the fainter regions to be greatly underexposed; conversely, optimum exposures of the fainter regions require the brighter regions to be strongly overexposed. Combining spectra optimized for different regions allow more uniform data quality over the entire spectrum. Generally, we preferred to combine simultaneous or near-concurrent large and small aperture spectra, using the small aperture data to fill in regions which were saturated in the large aperture spectra, especially for objects whose ultraviolet emission might be variable. The small aperture data which have been included in the merged spectra are indicated in Table 3.2 in §III by a letter S following the image number.

The small aperture for the long wavelength camera does not have the same relative responses as the large aperture (Holm and Bohlin 1985; Bohlin 1986). Instead, there is a systematic non-grey deviation between the small and large aperture responses. It was therefore necessary to correct all of the small aperture LWR and LWP fluxes for this effect. We applied the correction from Holm and Bohlin (1985), which is in agreement with Bohlin's (1986) correction. The corrected small aperture fluxes were then scaled uniformly, generally by factors of about two, to match the overall level of the most closely related large aperture spectra. Generally, we scaled to the co-exposed large aperture spectrum. If this did not exist or was heavily saturated, however, then we scaled to the average of the large aperture fluxes, or to the average of the best spectra when these were of disparate quality.

In contrast to the LWR and LWP, the SWP small and large apertures do have the same relative responses. It was therefore only necessary to scale these fluxes.

v) Correction for the Use of Narrowed Extraction Regions to Avoid Reseau Marks

IUE data are affected by camera reseau marks which fall within the spectral region, producing sharp, pseudo-absorption features in the extracted spectrum. For a given camera and aperture, the reseau marks generally occur at roughly the same wavelengths from spectrum to spectrum. However, the number and exact wavelengths of reseau marks which affect a particular spectrum may vary somewhat due to the positioning

of the object within the aperture, the width of the spectrum, and the THDA. Hence some spectra may be affected by a particular reseau mark while others may escape. Table 2.1 gives a list of approximate wavelengths for low dispersion spectra which are commonly affected by reseau marks in the various *IUE* cameras and apertures.

IUESIPS automatically flags data affected by reseau marks by setting $EPS = -800$. Hence, these data were excluded by our modified extraction routine, MAKENOEPS, and the fluxes corrected as described in §C. We noticed, however, that the correction algorithm often did not fully correct the affected fluxes, especially when the reseau marks covered many of the lines in the spectral region. The epsilons for these data were therefore not changed from -800 , in order to keep the data reduction as automatic as possible. This meant that fluxes at wavelengths affected by reseau marks were given zero weight when the individual spectra were merged (see §G below).

The widths and positions of the extraction regions were determined from the cross-cut profiles. When extracting spectra of point sources, which were not widened or trailed, we generally used the nominal region of 9 lines (18 lines for ELBL files). For wider spectra, we defined the regions using the line numbers where the cross-cut intensities fell to zero. This ensured photometrically accurate fluxes, but included peripheral reseau marks which affected only a few lines and which could have been avoided by narrowing the regions.

In most cases, the extracted spectra could be extrapolated smoothly over the peripheral reseau marks, so that no great amount of information was lost. However, spectra of objects with strong narrow emission lines were often adversely affected, and it was desirable to remove as many of the reseau marks as possible. In extracting these spectra, we therefore narrowed the regions to exclude reseau marks affecting only the edges of the region. Generally this meant using 5 or 7 lines for point sources (10 or 14 lines for ELBL files); in no case did we use regions narrower than 5 lines. The extracted fluxes were then scaled to match the overall level of the fluxes extracted from the full width spectral regions. Generally, the correction ranged from about 1-2% for 7-line extractions of point source spectra, up to about 20% for extractions of some extended sources. Table 2.2 gives a list of spectra extracted and corrected in this manner.

vi) Special Handling of Spectra for Solar System Objects

Solar System objects pose unique problems because 1) they move and can therefore be difficult to track, 2) they are not point sources and often do not emit uniformly from their surfaces, and 3) their spectra vary in brightness and sometimes in shape depending on distance from the sun and/or the Earth. Spectra taken at different epochs can therefore be extremely difficult to match. Great care was taken to ensure that all images used for a particular object were exposures of the same region on its surface, and were confined to as limited an epoch as possible. Even so, special treatment was required for spectra of some of the Solar System objects.

For the most part, special treatment was required when one spectrum matched the other spectra for a particular object in shape, but differed in overall brightness. This was the case for Mars (LWP 4643), Vesta (LWR 6106), and Jupiter (SWP 17610); in such instances the disparate spectrum was simply scaled to match the average flux level. Similarly, the short wavelength spectra for Venus were scaled to match the average of the long wavelength spectra, in the region of overlap.

The Moon, however, was a particularly difficult case; not only was there disagreement among the short and long wavelength spectra separately, but the average levels of the short and long wavelength spectra disagreed as well. We therefore averaged all of the large aperture short and long wavelength data over the small region of overlap, and scaled all of the spectra to match this average. This was not a completely satisfactory fix, however, as the shapes of some of the spectra seemed to differ as well as their overall brightnesses. The apparent sharp edge in the spectrum at $\sim 3100\text{\AA}$ is actually an artifact caused by this change in spectral shape, as we have spliced together spectra which were forced to agree at the short wavelength end, but which therefore disagree at the long wavelength end. The apparent features at $\sim 1650\text{\AA}$ and $\sim 1780\text{\AA}$ may be artifacts as well.

F. CHECKING FOR ARTIFACTS, AND EXCLUSION OR INCLUSION OF DATA FOR SPECIAL PURPOSES

After the calibration and various corrections, a final check of each individual spectrum was made. The spectra were carefully compared with the photowrites and the line-by-line plots, and any features in the spectrum which were judged not to be real, or not to have been correctly handled by the extraction algorithm, were excluded by interactively setting $\text{EPS} = -600$.

In some cases, bad data were included, and good data excluded, for special purposes. Saturated data for strong emission lines were included when no unsaturated data for these were available in the archives. This was accomplished by interactively setting $\text{EPS} = -200$ before the spectra were merged, and subsequently changing EPS to -1400 in the final spectrum. In some cases, good data were excluded when combining spectra whose exposure times were optimized for regions of very different intensity. In such cases we improved the data quality by excluding noisy data covering faint spectral regions from the spectra optimized for the brighter regions. Again the data were excluded by setting $\text{EPS} = -600$.

In spectra of three objects – Comet Austin, NGC 1068, and NGC 4151 – we merged short SWP exposures, for which no geocoronal Lyman α emission was visible, with longer exposures. Data covering geocoronal Lyman α were excluded from the longer exposures, and all but the Lyman α data were excluded from the short exposures. In this way we were able to remove the geocoronal Lyman α emission from these spectra, and to plot only the Lyman α emission intrinsic to these objects.

Table 2.3 gives a list of those spectra where data were included or excluded for special reasons.

G. ALIGNING AND MERGING INDIVIDUAL SPECTRA

The final step before merging individual spectra into one final spectrum was to align the spectra in wavelength. This was done by adopting one of each set of spectra as a wavelength standard and cross-correlating the other spectra against it. The standard was chosen to be the spectrum with the best quality data covering the widest range; usually this meant the spectrum with the longest exposure and the least amount of saturated data. The routine solved for the relative wavelength shift which maximized each cross-correlation function, and these relative shifts were adopted as constant offsets from the standard spectrum. Each set of correlations was done over several wavelength ranges in order to obtain the best overall match for each spectrum. For bright objects (*i.e.*, which could be easily detected with the FES), these relative shifts were generally small as expected, and zero relative shifts were adopted. For fainter objects, especially those for which blind offsets were necessary, relative shifts of up to $6\text{-}8\text{\AA}$ were sometimes required. For some objects, such as BL Lac objects, the spectra do not show obvious features which can be matched and correlating the spectra would not be meaningful; zero relative shifts were adopted in these cases.

The next step after determining the best relative shifts was to merge the spectra. The short wavelength and long wavelength spectra were first averaged separately. Each individual spectrum was shifted relative to the standard spectrum, resampled by linear interpolation to the same wavelength scale, and weighted linearly according to exposure time. The averaging was done using the standard RDAF routine IUEMERGE. Only data with $\text{EPS} \geq -200$ were averaged; data affected by blemishes, excluded data, data affected by reseau marks, and saturated data were given zero weight. Extrapolated data (along with saturated data included for plotting purposes) were included with relative weights of 1% and affected the averages only in pixels where no good data existed.

The separately summed short and long wavelength spectra were then merged into final spectra. Fluxes in the overlap region between the short and long wavelength ranges were weighted by the exposure times and averaged, after the long wavelength fluxes had been resampled to the same wavelength scale as the short wavelength fluxes. In practice, this was only done for the Seyfert galaxy and QSO spectra, as the SWP spectra for all other objects were truncated at 1950\AA , the first wavelength of the long wavelength spectra. The short and long wavelength sums were not shifted relative to one another in wavelength.

The positive epsilon values assigned to the final fluxes represent the relative numbers of data points, weighted by exposure time (or 1% of exposure time for extrapolated data), which contributed to those fluxes. Hence, in the final spectrum, good data may have epsilon values ranging from $\text{EPS} \sim 0$ to $\text{EPS} = 100$. If only extrapolated data contributed at a particular wavelength, then the epsilon was set to $\text{EPS} = -200$. If all of the

data at a given wavelength were excluded, then that flux was flagged with the maximum (*i.e.*, least negative) of all the epsilon values. The epsilons for saturated data which had been included for plotting purposes were set to $EPS = -1400$.

The final spectra were checked one last time for artifacts introduced during the merging process. In some cases where spectra were shifted and resampled, noise "spikes" were generated at the edges of data affected by reseau marks. In addition, concurrent SWP and LWP spectra of the same object often do not join smoothly in the overlap region, especially when the LWP spectra are optimized for the longer wavelength ($\lambda > 2800\text{\AA}$) region. This mismatch between SWP and LWP spectra is well known, and can produce strong pseudo-emission features in the overlap region. The reseau spikes and mismatch artifacts were removed from the final plots by flagging these fluxes with $EPS = -600$.

All of the steps subsequent to the creation of the one-dimensional MELO files, starting from the calibration of the individual spectra and ending with the merging into final spectra, were done using CURDAF format (".LOW" extension) files. A record of the processing for each individual spectrum was created by documenting each step in the corresponding history (".HDR" extension) file. Once the merged spectra were in final form, the files were converted back into GSFC RDAF IUESAVE format (".SAV" extension). A history file was created for each merged spectrum by appending abbreviated versions of the individual history files to a brief record of how the merged spectrum was created.

H. GENERATION OF FLUX TABLES AND SPECTRAL PLOTS

The final merged fluxes were used to generate the spectral plots. To produce the flux tables, the merged fluxes were averaged in 5\AA bins over the range of 1150\AA to 3200\AA , using the standard RDAF routine WBINS. Data flagged with $EPS < -200$, that is, data affected by blemishes or reseau marks, interactively excluded data, and saturated data, were given zero weight and did not contribute to the binned fluxes. All data flagged with positive epsilons (*i.e.*, good data) were given equal weight, while data flagged with $EPS = -200$ (*i.e.*, extrapolated data) were included with a relative weight of 0.5. The flux tables and spectral plots are presented in §V.

TABLE 2.1

WAVELENGTHS OF RESEAU MARKS WHICH CAN AFFECT LOW DISPERSION *IUE* SPECTRA

Camera	Aperture	Wavelengths ¹ (Å)
SWP	Large	1660, 1780, 1920, 1190, 1320
	Small	1460, 1580, 1720, 1860
LWP	Large	3260, 3040, 2840, 2630
	Small	3160, 2000, 2230, 2440
LWR	Large	2780, 2050, 2580, 3300, 2380, 3100
	Small	3100, 2380, 2170, 2690, 1970

¹Wavelengths of reseau marks given in order of increasing line number

TABLE 2.2

A LIST OF SPECTRA EXTRACTED USING NARROWED REGIONS

Object	Description	Plate No.	Images (no.of lines)
Jupiter		2	SWP 25730L (13)
Comet Austin		5	SWP 17498L (7)
AU Mic	in quiescence	10	SWP 6430L, 6433L, 6434L (5), 6431L (7); LWR 5530L, 5531L, 5532L, 5533L, 5534L (7)
Gliese 867A	in quiescence	11	SWP 21239L (7), 21240L (9); LWR 16930L, 16931L (7)

III. ASTRONOMICAL OBJECTS AND CATEGORIES

All objects presented in the *Atlas* are given in Table 3.1 in the order of their Right Ascension. The coordinates for the Solar System Objects are left blank because the data for a given object were obtained at different positions in the sky. The reader can consult Table 3.2 and Table 6.1 for the image number and time of each observation. Then look up the observing scripts which are maintained at the *IUE* Observatory, or use the time of observation and *The Astronomical Almanac*, to estimate the apparent Right Ascension and Declination of each observation. The accuracy of the 1950 coordinates reported in Table 3.1 is not uniform. The references from which we adopt the coordinates are given in Column 4. We try to give the original discovery paper for those objects which we do not have more precise coordinates. We took the coordinates of several objects from the *IUE* observing scripts. The ROB stars are the blue horizontal branch stars of the globular cluster NGC 6397 reported in *Royal Observatory Bulletin* No. 43 (Wooley *et al.* 1961). The center of NGC 6397 is $\alpha(1950) = 17^{\text{h}} 36^{\text{m}}$, $\delta(1950) = -53^{\circ} 39'$ (Alcaino and Liller 1980). We also searched the SIMBAD data base and obtained the 1950 coordinates for some of the objects in the *Atlas*. In Table 3.1, the observed V and B-V for each object are also given, together with notes and the references from which the magnitudes and colors were obtained. For variable objects, the reader should consult Table 6.1 which gives the V magnitude derived from the Fine Error Sensor (FES) counts (see Imhoff and Wasatonic 1986). These FES counts were measured for objects with $V \leq 14.5$ immediately before a given target was maneuvered into the desired aperture for exposure. Therefore, the FES provided V magnitude is generally available for every image when the target is brighter than $V \sim 14.5$.

Table 3.2 lists the astronomical categories, sub-categories and individual objects in each of them. Abbreviated 1950 Right Ascension and Declination are provided such that cross reference can be made with Table 3.1. Table 3.2 also lists the *IUE* images which were included in making the plots and flux tables of the *Atlas*. The letters L and S following the image number indicate large and small aperture data, respectively. Generally we attempted to select well exposed, large aperture images with low background levels and as few blemishes as possible. It was sometimes necessary to combine spectra of different exposure levels, especially for objects whose ultraviolet spectra show a large range in intensity. In such cases, we attempted to combine spectra obtained as nearly concurrently as possible.

In this *Atlas*, we attempt to include a wide selection of categories of astronomical objects. Some categories are better represented than others for several reasons: 1) the availability of good or reasonably good data, 2) the availability of already processed data (*e.g.* Dr. C. Cacciari kindly provided merged data for

stars in category 12.1), and 3) the research interests of the authors. In the following, we briefly point out other considerations which contributed to the selection of the particular objects or images for each of the categories.

Category 1 **Solar System Objects** – The spectra were obtained with the observing aperture positioned at the center of each object.

Category 2 **Pre-Main Sequence Stars** – We include objects which are well recognized in their respective categories. Also, each object has relatively good SWP and LWR data obtained at about the same time.

Category 3 **Late Type Stars** – The SWP data are available for all stars to illustrate the ultraviolet spectral properties of cool star chromospheres and transition regions. The spectra obtained during stellar flares are compared with those observed when the stars (flare stars and λ And in the RS CVn stars subcategory) were more quiescent. RS CVn stars are close binaries, two different orbital phases are shown for the prototype system RS CVn. More comprehensive presentation of the photospheric ultraviolet spectrum of late type stars is available in Wu *et al.* (1983, 1991).

Category 4 **Chemically Peculiar Stars** – We attempt to provide a good sample of different subtypes of Peculiar A stars in this category. For R CrB, the spectrum designated “at maximum flux” is a weighted average of the spectra obtained during the 1978 December 2 – 1982 March 9 period when it was at a bright state with the *IUE*FES magnitude between 5.89 and 6.16. Several observations were made starting 1983 September 1 when the star declined to FES magnitude 8.50 and fainter. But these data are not presented in the *Atlas* because of poor quality shortward of 2000Å. Instead, the spectrum designated “at minimum flux” is actually the combination of those obtained on 1984 May 15 when the star had recovered from minimum and its brightness rose to a FES magnitude of 7.30. A study of R CrB based on these spectra is given in Holm *et al.* (1987).

The carbon stars are peculiar giants whose optical and infrared spectra are characterized by strong bands from molecules such as C₂, CH and CN. They are thought to be asymptotic giant branch stars showing evidence of interior mixing of carbon-rich material to their surfaces. They were originally classified in the Henry Draper Catalogue as R and N type stars, with the R stars having atomic lines and continua like G–K giants, but exhibiting strong bands like the cooler N stars. This classification scheme was essentially a temperature one, with the two classes merging such that the latest R-types were difficult to distinguish from the early N-types. Keenan and Morgan (1941) revised the classification system by recognizing that stars of similar temperature, based on the atomic-line spectrum and color, would show different carbon band strengths. Thus they classified stars using two indices, the first a measure of temperature, the second related to carbon strength, and hence, carbon overabundance.

The ultraviolet spectra of the carbon stars have been discussed by Eaton *et al.* (1985) for the R stars, and by Johnson and Luttermoser (1987) for the cooler, N types. In low dispersion, the early R stars are nearly indistinguishable from G–K stars, while the later R and N types have enhanced low-level neutral lines due to the extreme cooling in their surface layers. Due to the intrinsic faintness of these stars, *IUE* spectra covering the full range of temperature and abundance types are not available. We have selected objects covering the temperature range accessible. Also shown is the hydrogen-deficient carbon supergiant HD 182040. Spectral types are given in Table 3.2, both those on the refined Harvard system by Shane (1928), and Keenan-Morgan types, supplemented with types by Yamashita (1972, 1975), as collected by Eaton *et al.* and Johnson and Luttermoser.

Category 5 Pulsating Variables – The phases (maximum, minimum) for X Ari and RR Lyr are estimated from those given in Bonnell and Bell (1985) which are based on *IUE* ultraviolet light curves. The phases for δ Cep are those given in Parsons (1980) and Schmidt and Parsons (1982) which are based on optical photometry and *IUE* FES magnitudes.

Category 6 Subluminous Stars – The properties of four subdwarf classes SdB, SdOB, SdO and hot Sd are summarized in Vauclair and Liebert (1987). The spectral classification system for white dwarfs is described by Sion *et al.* (1983) and the spectral type for the stars included in subcategory 6.2 are mostly from McCook and Sion (1987). Note that PG 1159–03 (GW Vir) is the prototype of the “PG 1159” stars, a class of very hot, helium-rich pulsating variables (see Vauclair and Liebert 1987).

Category 7 Interacting Binary Systems – The systems in this category are ordered roughly in increasing orbital period. Three broad categories of interacting binaries are included: 1) The contact systems, or W Ursae Majoris stars, each system consists of two stellar cores imbedded in an optically thick common envelope whose shape is roughly that of an equipotential surface. 2) The Algol and related systems, one component (the cooler secondary in the Algols) in these systems are thought to fill approximately the critical Roche equipotential surface and transfer mass, in a gas stream probably through the inner Lagrangian point, to the other component and out of the binary system. And 3) the wide binaries which have periods longer than about 100 days. These systems consists of a cool evolved primary and a hot secondary, and display mass transfer and systemic mass loss via stellar winds.

Category 8 Cataclysmic Variables and X-ray Binaries – We thought that a brief clarification is called for concerning magnetic cataclysmic variables. Like dwarf novae, magnetic CVs also have a red dwarf secondary which fills the critical Roche equipotential surface and transfers mass to the white dwarf primary through the inner Lagrangian point. But unlike the dwarf novae, the magnetic CVs have a strong magnetic field which influences how the transferred mass reaches the white dwarf surface. There are two subtypes of magnetic CVs: 1) AM Her stars, or polars (see reviews by Cropper 1988, and Beuermann 1988), which have

a magnetic field of a few times 10^7 gauss. In AM Her stars, matter is channelled directly onto the white dwarf surface around one or both magnetic poles without the formation of an accretion disk. Furthermore, the rotation of the white dwarf is synchronized with the orbital motion of the binary system. E 1405–451 (V834 Cen) is another AM Her star. 2) DQ Her stars, or intermediate polars (reviewed by Mason, Rosen and Hellier 1988), which have somewhat weaker magnetic fields and accretion disk is formed around the white dwarf. However, the magnetic field of the white dwarf disrupts the inner region of the accretion disk and material then flow from there onto the white dwarf magnetic poles. In DQ Her stars, the white dwarf rotation period is less than the binary orbital period. EX Hya and GK Per are the other DQ Her stars in this *Atlas*. Note that GK Per and DQ Her are included in subcategory 8.3, Old Novae.

WZ Sge should have been included in subcategory 8.1, Dwarf Novae. It had long been called a recurrent nova. But it is actually a dwarf nova with a very long outburst cycle, as demonstrated by its optical and ultraviolet spectral characteristics during outburst and at minimum (Sparks *et al.* 1980, Fabian *et al.* 1980, and Holm 1988).

Category 9 Supernovae – The production of spectral plots and flux tables were completed before Supernova 1987a was discovered. Therefore, no data from Supernova 1987a is included here.

Category 10 Luminous Stars – For the Wolf-Rayet stars, we took care to select only isolated, non-eclipsing systems, which are not imbedded in planetary nebulae and which do not otherwise have strange properties not characteristic of the class as a whole.

Category 11 Nebulae – For the H II regions, the Orion Nebula pointing was selected to avoid stars in the large aperture. Therefore, the spectrum is a combination of dust scattered star light plus nebula emission. NGC 604 was observed with the large aperture ($10'' \times 20''$) pointing at the center of the object, the spectrum is the sum of direct star light, nebula emission and dust scattered light. A good collection of *IUE* spectra of extragalactic H II regions is given in Rosa, Joubert and Benvenuti (1984).

Planetary nebulae are ordered in decreasing excitation class. The excitation class is based on the optical nebular spectrum and is an indication of the degree of ionization of various elements (Aller 1956, Feast 1968, and Webster 1976). Class 10 has the highest excitation, and Class 1 has the lowest. Pottasch (1984) lists the excitation class for a large number of planetary nebulae. In several objects, the spectra are dominated by the continuum of the central star.

Category 12 Population II Stars – Except for HD 130156, all stars in subcategory 12.1, Population II Stars in the Field, are from Cacciari (1985). The spectral type of these stars as tabulated in Cacciari range

from A0 to M3, and they are arranged in this *Atlas* in that order. The spectral type of HD 130156 is obtained from the SIMBAD Data Base. Additional *IUE* observations of field population II stars are discussed in Huenemoerder, de Boer and Code (1984). Blue horizontal branch (BHB) stars in NGC 6397 (subcategory 12.2) are from de Boer (1981). The stars are designated by their *Royal Observatory Bulletin* (ROB) number as given in Wooley *et al.* (1961). UV bright stars in other globular clusters are discussed in de Boer (1985). Note that HD 222107, or λ And, is also presented in subcategory 3.2 as a RS CVn star.

Category 13 Globular Clusters – The objects were selected to provide a range in metallicity, $[Fe/H] = -0.44, -1.25, -1.42,$ and -1.57 respectively for 47 Tuc, M5, M13 and M3 (Harris and Racine 1979). Observations were made with the large aperture pointing at the center of each cluster.

Category 14 Extragalactic Objects – For extended objects, we selected those observations which had the large aperture pointing at the center of the galaxy. For M31, therefore, the spectrum is that of the nuclear bulge which has stellar populations similar to those in elliptical galaxies. In this category, we attempted to include a sample of different galaxies and active galaxies. Active galaxies are well represented, reflecting the availability of a large amount of good *IUE* data. For Seyfert galaxies, we have objects which span a range in luminosity; and I Zw 1 and Mrk 478 which are known to show strong optical Fe II emission (Osterbrock 1977, Phillips 1977). Variability is highlighted in presenting the spectra of broad line radio galaxies and BL Lac objects. Quasi-stellar objects were selected such that there is a range of redshift in the sample.

Notes to Magnitudes and Colors:

- a. average value
- b. Johnson blue magnitude
- c. Stromgren y magnitude
- d. Stromgren (b-y) color
- e. V_E photoelectric visual magnitude
- f. FES magnitude
- g. V_G in Genova system
- h. depending on orbital phase
- i. integrated V magnitude as determined from concentric aperture photometry
- j. B-V color index of sub-giant branch at horizontal branch level as determined directly from color magnitude diagram
- k. within 15" diameter aperture
- l. brightest magnitude observed
- m. faintest magnitude observed
- n. Visual nebular magnitude, estimated from Perek and Kohoutek (1967), (V, B-V) magnitudes for central stars are as follows:
 NGC 246 (11.95, -0.37) (AI);
 IC 418 (10.33, -0.20) (AJ);
 IC 2149 (11.59, -0.31) (AJ);
 BD+30 3639 (10.10, -0.06) (AI)
- o. v magnitude in narrow band photometry in Smith's (1968a, b) system
- p. b-v color in narrow band photometry in Smith's (1968a, b) system
- q. during quiescence
- r. derived magnitude and color
- s. magnitudes and colors measured using smallest apertures. Apertures (in arcsec) are as follows:
 22.5 (NGC 7582), 11.6 (NGC 7714),
 7.8 (Mrk 335), 17 (I Zw 1), 22.5 (Fairall 9),
 10.4 (NGC 1068), 17 (Mrk 9), 9.7 (NGC 3783),
 7.5 (NGC 4151), 10.1 (Mrk 478),
 9.7 (ESO 141-G55), 7.6 (3C 120),
 12.2 (3C 382), 12.2 (3C 390.3), 15.4 (3C 273)
- t. total integrated galaxy magnitude and color
- u. approximate value during period of IUE observations

IV. ACKNOWLEDGMENTS

It is a great pleasure to acknowledge the assistance provided by our research associates, the advice received from our astronomical colleagues, and the resources made available to us by NASA and the Space Telescope Science Institute. We are in debt to their invaluable support.

James Blackwell, Jr., Ruth Bradley, Patricia Pitts, Michelle Fitzurka, and Deanna Wilson-Diaz helped us in data management, library research, making the spectral plots and flux tables, and editing the text of this *Atlas*. Randy Thompson, Dr. Carol Grady, Rosalie Ewald, and Keith Feggans assisted us in using the data reduction system at the *IUE* Regional Data Analysis Facility located at the Laboratory for Astronomy and Solar Physics of the NASA Goddard Space Flight Center. Sarah Stevens-Rayburn and the Space Telescope Science Institute Library made available to us much of the reference publications cited in this *Atlas*.

Dr. Bruce Altner recommended the most suitable *IUE* images, and the references for positions and magnitudes for the selected globular clusters. He also provided the reduced spectra for ϵ Aur at the phase closest to the center of eclipse. Dr. Carla Cacciari sent the FITS tape containing her published spectra of Population II stars. Dr. Nancy Evans helped in the selection of spectra for Cepheid and RR Lyrae variables. Dr. Kenneth Jensen helped in compiling the list of flare stars, and provided general information on flare stars and cataclysmic variables. Dr. Anne Kinney assisted in the selection of high-redshift quasars and their spectra, and had discussions with us on high z quasars. Dr. Keith Mason advised us in establishing the lists, and obtaining the references for dwarf novae, magnetic cataclysmic variables, and X-ray binaries. Dr. John Nousek helped in identifying the spectra which is most appropriate for the AM Her object E 1405-451. Dr. Nancy Oliverson provided references for symbiotic star magnitudes, and pointed out the outburst phase and spectra of Z And. Dr. Robert Panek took interest in the *Atlas* project during its early phase and provided the list of peculiar A stars. Dr. John Raymond advised us in the selection of spectra for the Cygnus Loop, the Vela SNR, and AM Her. Dr. Francis Schiffer assisted in the development of the production software for making the spectral plots and flux tables. Dr. Richard Shaw provided references for the excitation class of planetary nebulae. Drs. Anna Torres and Philip Massey helped in establishing the sequences of WC and WN stars, and in the selection of candidate stars which were single, least reddened, and not imbedded in planetary nebulae. They also provided general information on Wolf-Rayet stars, and references for positions, magnitudes, and classification. Dr. Barry Turnrose recommended the spectra for the Orion Nebula. Dr. Frederick Walter helped us put together the list of RSCVn stars, and provided general information on RSCVn stars. Dr. Wayne Warren provided us with invaluable assistance in accessing the SIMBAD data base for references, positions, and magnitudes of some of the objects in our *Atlas*.

The data reduction for this *Atlas* was performed at the *IUE* Regional Data Analysis Facility in the Laboratory for Astronomy and Solar Physics of the NASA Goddard Space Flight Center. The spectral plots and flux tables were made with the science computer at the Space Telescope Science Institute. This project was partially supported by the NASA research contract NAS 5-28749 to the Computer Sciences Corporation.

V. THE *ATLAS*

In this section, we present the spectral plots and tables of fluxes at 5Å bins. These are observed spectra, no correction for reddening by dust has been applied to any of the data. In order to show weak features in spectral regions of very low flux levels, plots in expanded flux scales are given either as an insert to the regular plot or on a separate plate. These inserts and separate plates are provided only for those spectra that have sufficiently high signal to noise ratio.

The following conventions were adopted in the plots and flux tables: 1) Pixels and bins containing only bad data, and data affected by reseau marks, were left blank. 2) In most cases, pixels containing only saturated data were also left blank. In cases where saturated data were included especially for plotting purposes, the data were plotted with pluses. In the flux tables, these entries were indicated by asterisks. 3) Extrapolated data were treated as good data, and no special symbols were used.

The *Atlas* is organized by astronomical categories, and spectral plots and flux tables of the objects in the *Atlas* are identified by plate numbers. The Table of Contents gives the plate numbers associated with each astronomical category. Table 3.1 lists all objects presented in the *Atlas* in the order of their Right Ascension, together with their V, B–V, and plate numbers. Table 3.2 provides the connection between astronomical categories, objects included in each category with their abbreviated Right Ascension and Declination, *IUE* images used for making the spectral plots and flux tables, and plate numbers.

FLUX-1: Eta Car (Very Luminous Star in Galaxy)
FLUX-2: P Cyg (Very Luminous Star in Galaxy)

Table with 10 columns: WAVE, FLUX-1, FLUX-2, WAVE, FLUX-1, FLUX-2, WAVE, FLUX-1, FLUX-2, WAVE, FLUX-1, FLUX-2, WAVE, FLUX-1, FLUX-2, WAVE, FLUX-1, FLUX-2. It contains spectral data for two stars: Eta Car and P Cyg.

Plate 103

FLUX-1: S Dor (Very Luminous Star in LMC)
 FLUX-2: LMC S30 (Very Luminous Star in LMC)

FLUX-1: IZW 18 (Dwarf Irreg Galaxy)
FLUX-2: NGC 4449 (Irreg Galaxy SmlV)

Plate 141

Table with 12 columns: WAVE FLUX-1, FLUX-2, WAVE, FLUX-1, FLUX-2, WAVE, FLUX-1, FLUX-2, WAVE, FLUX-1, FLUX-2, WAVE, FLUX-1, FLUX-2. The table contains a grid of spectral data points for two galaxies.

VI. IUE IMAGES USED IN THE ATLAS

The IUE images used in the production of this *Atlas* are listed in Table 6.1. Column 1 gives the image number, designated by the camera and followed by a sequential number. LWP, LWR, SWP, and SWR are the Long Wavelength Prime, Long Wavelength Redundant, Short Wavelength Prime and Short Wavelength Redundant camera, respectively. SWR had not been used for routine observations because of hardware problem experienced early in the IUE mission. Column 2 is ALT, A stands for aperture used: L (large) is the 10 by 20 arc second oval aperture; S (small) is the three arc second circular aperture. The L column of ALT is to indicate the configuration of the large aperture: O \equiv opened; C \equiv closed. The T column shows how the exposures were made: blank \equiv single exposure. We attempted to select the exposures for which the target is centered in the aperture. T \equiv trailed exposure obtained by trailing the target along the long axis (or the X-axis) of the large aperture. For the low dispersion mode in which all spectra in this *Atlas* were obtained, the X-axis is perpendicular to the dispersion direction. M \equiv multiple exposures taken by placing the target on discrete locations along the X-axis of the large aperture. During a trailed exposure, the motion of the spacecraft is controlled by gyros. If the time required to trail the target is more than a few minutes, the inaccuracy of the gyro control and the changing thermal condition of the telescope may lead the target to move also in the Y-axis direction and cause wavelength smearing. Therefore, for faint objects, the observer can improve the signal to noise ratio of the data by taking discrete exposures when the target is placed at different locations along the X-axis and the spacecraft is stabilized by tracking on a guide star. Sometimes, this multiple exposure technique is called pseudo-trail technique. The trail and pseudo-trail techniques improve the quality of the spectra in several ways: 1) more photons are collected, 2) at a given wavelength, the data are recorded on more pixels, therefore, the fixed pattern read-out noise has a better chance of being averaged out, and 3) the spectra are wider which allow blemishes such as reseaux, cosmic-ray hits, hot pixels, etc., be excised and data repaired reliably. E \equiv exposures taken on extended sources. For these exposures, the orientation of the large aperture may be important. The derivation of the orientation of the large aperture on the sky is discussed by Schiffer (1980) and repeated in Sonneborn *et al.* (1987). Column 3 is the identification of the object. Column 4 gives the V magnitude derived from the Fine Error Sensor (FES) counts recorded on observing scripts and *Merged Log of IUE Observations*. To convert FES counts to V_{fES} , we adopted the algorithm of Imhoff and Wasatonic (1986) which are reproduced here for convenience.

1. Correct the FES sensitivity degradation:

$$CC = FES\ Counts / [0.98568 + 0.00791(T - 1978.0) - 0.00396(T - 1978.0)^2] \quad (6-1)$$

2. Compute the color-correction term:

$$COLOR = -0.271087(B-V) - 0.063880(B-V)^2 + 0.137764(B-V)^3 \quad (6-2)$$

3. Compute the V_{fes} magnitude:

$$V_{fes} = -2.5 \log [CC/(1 - 1.2 \times 10^{-4} CC^{0.781})] + COLOR + K \quad (6-3)$$

Where $T =$ date of observation in decimal years.

$K =$ 11.16 for FES fast track underlap (FU) mode.

$K =$ 16.52 for FES fast track overlap (FO) mode.

$CC = CC/4$ for FES slow track (SO) mode which operates only in overlap and integrates four times longer than the fast track mode.

Note that the term in the denominator of the third equation is the dead-time correction needed for bright stars (with FES counts > 5000). Comparison with published photometry shows that V_{fes} has a RMS error of about 0.07 magnitude. Other entries in Column 4 are BI off \equiv blind offset from a nearby target (a star or a satellite of the planet), Offset \equiv offset (same as blind offset), No rec \equiv no FES counts recorded on the observing script. For LWR 4905 and 5258, we give the lower limit for the V_{fes} of the supernova in M100 because the body of M100 galaxy contributed significantly to the measured brightness. The question mark for ROB 584 (SWP 9279) indicates that nearby stars may contaminate the measured FES counts. Notes are also provided for some entries in Column 4. Column 5 gives the observing program under which the data were taken. The observing programs with their respective Principal Investigators are published in the *Merged Log of IUE Observations*. Column 6 is the date of observation. The first number is the year minus 1900, and the second number is the day of the year. Column 7 gives the start time of the exposure in hour and minute. Column 8 is the exposure time in minutes and seconds. Column 9 is for comments, V and G indicate that the data were read down at VILSPA station and Goddard Space Flight Center, respectively. The exposure level of the VILSPA images are presented in a three digit code, the reader should consult the *Merged Log of IUE Observations* for further information. The exposure level of Goddard images are generally given in three numbers separated by slashes. Each is the Data Number (DN) measured by the Telescope Operator during the quick-look analysis with the Guest Observer. The DN goes from 0 to 255, such that the detector is saturated at 255. The first number is the maximum DN for the strongest emission line on the spectrum, the second number is the maximum DN level for the most heavily exposed portion of the continuum, and the third number is the average DN for the background adjacent to the spectrum. If the quick-look data do not reveal any obvious emission lines, the first number is omitted. If the spectrum is overexposed with saturation, the roughly estimated number of times of overexposure is given. For example, if the strongest emission lines is ten times overexposed, the first number will be 10x. Some entries in Column 9 are non-standard, but they are usually self-explanatory.

Notes on calculating V_{fes} :

- a: assumed $(B-V) = 0$
- b: used $(b-v)$ *i.e.* Stromgren $H\beta$ photometry
- c: V_{fes} = those from Benvenuti *et al.* (1982)
- d: used $(B-V)$ within $15''$ aperture
- h: used $(B-V)$ from Greenstein (1984)
- g: used $(B-V)_g$ *i.e.* colors for globular clusters' giant branch
- G: used $(B-V)$ of the Genova system
- m: used mean $(B-V)$ (for variable stars)

VII. ERRATA

After the production of the plates and tables, a few minor errors were found. For a variety of reasons it was impractical to go back and correct these errors. For this reason, they are listed here for your reference.

1. Plate 33, Delta Cep, binned SWP fluxes were inadvertently left out of the flux table.
2. Plate 120, HD 19445, the published spectral type ranges from A4p to F2.
3. Plate 122, HD 140283, the published spectral type and luminosity class are F3 VI.
4. Plate 123, HD 130156, the published spectral type ranges from A3m to F3.
5. Plate 135, HD 186776, the flux table should be blank at wavelengths shortward of 1956 Å.

13. ABSTRACT (Maximum 200 words) This IUE Ultraviolet Spectral Atlas of Selected Astronomical Objects (or "the Atlas"), is based on the data that were available in the IUE archive in 1986, and is intended to be a quick reference for the ultraviolet spectra of many categories of astronomical objects. It shows reflected sunlight from the Moon, planets, and asteroids, and also shows emission from comets. Comprehensive compilations of UV spectra for main sequence, subgiant, giant, bright giant, and supergiant stars are published elsewhere. This Atlas contains the spectra for objects occupying other areas of the Hertzsprung-Russell diagram: pre-main sequence stars, chemically peculiar stars, pulsating variables, subluminoous stars, and Wolf-Rayet stars. This Atlas also presents phenomena such as the chromospheric and transition region emissions from late-type stars; composite spectra of stars, gas streams, accretion disks and gas envelopes of binary systems; the behavior of gas ejecta shortly after the outburst of novae and supernovae; and the H II regions, planetary nebulae, and supernova remnants. Population II stars, globular clusters, and luminous stars in the Magellanic Clouds, M31, and M33, are also included in this publication. Finally, the Atlas gives the ultraviolet spectra of galaxies of different Hubble types and of active galaxies.
