1.0 INTRODUCTION

The NASA Earth Radiation Budget Satellite (ERBS) spacecraft, which was launched into a 57-degree inclination orbit on October 5, 1984, became operational on November 1, 1984, and was the only operational ERBE spacecraft during that year. The National Oceanographic and Atmospheric Administration NOAA-9 spacecraft was launched into a polar, Sun-synchronous "noon/midnight" orbit on December 12, 1984. The NOAA-9 did not become operational until February of 1985. The NOAA-10 satellite was launched into a polar, Sun-synchronous "terminator" orbit in October 1986 and became operational in that month.

2.0 SCANNING RADIOMETERS

The relative positions of the scanner at various elevation angles are shown in Figure 1. The sector from 14 to 22 degrees is sometimes called the "space look before scan," the sector from 22 to 158 degrees is called "Earth-viewing," and the sector from 158 to 163 degrees is called "space after scan." The complete design and method of operation of the scanners was described by Carman¹ and Kopia². Data for scanner offsets are obtained from pre-Processed Archival Tapes (also called pre-PAT's or ID-3's) produced by the ERBE Merge Subsystem. The Merge Subsystem and the ERBE scanner count conversion process is fully described by Stassi et al.³. The ERBE scanners complete one scan every 4 seconds; hence, there are four scans in each telemetry record. A space-view is obtained every scan and is the source of the "space clamp" offset, which is applied to all measurements in a scan to adjust for drift. The scan position offsets are scan position specific, and these are the offsets listed in this report. The units associated are Watts per square meter per steradian. It is important to mention here that the scan positions referred to in this report, which range from 1 to 60, are known as the "Earth-viewing" scan positions, and they differ from the sample numbers listed in other documents (e.g., Section 4, Reference 4), which range from 1 to 74. The conversion from the "Earth-viewing" scan position to sample number is performed by adding 8 to the scan position. Thus, sample numbers 1 to 8 are the "space-viewing" positions, 9 to 68 are "Earth-viewing," 69 and 70 are "space-viewing," and 71 to 74 are the "internal blackbody (IBB) viewing" positions. The nadir position in the "Earth-viewing" system is scan position 34, while it is sample number 42.

2.1 GROUND OFFSETS AND THE SCANNER COUNT CONVERSION ALGORITHM

Halyo et al.⁵, modeled and determined the count conversion coefficients using the TRW ground calibration data documentation^{4,6,7} for all ERBE scanning sensors. A more detailed description of the scanner count conversion process is given by Lee et al.⁸. The accuracy of the ERBE scanners was shown by Lee et al.⁹, to be within 1 percent. Stassi et al.³, detailed the software applications of the count conversion algorithms as they are used by the ERBE Merge Subsystem. In abbreviated form, the following equation characterizes the scanner count conversion algorithm used:

$$E_{scan} = GAIN * (raw\ counts - (scan\ position + space\ clamp\ count\ offset)) \\ + scan\ offset\ for\ the\ record + drift\ offset\ for\ the\ scan$$

Figure 1. ERBE Scanner Elevation Angles

where: $GAIN = (AV/VB) * CVLT$ and
AV - a constant for the channel determined from ground calibration data.
VB - bias voltage counts for the channel
CVLT - a counts to voltage conversion factor (-1/409.5)

2.2 ERBS SCANNER OFFSET PROCEDURES

Halyo et al.⁵ determined the ERBS ground count conversion coefficients (gains). The ERBS zero-radiance offsets (by scan position) were derived by B.R. Barkstrom, using space-view data from the 1984 pitch-up maneuvers. The 1985 pitch-up maneuvers were used to verify that the ERBS in-flight scanner offsets had not changed. Major differences were found, however, between the scanner offsets, when operated at the along-track azimuth position and those found when operated at the cross-track position. Appendix A contains the ERBS cross-track and along-track scanner offsets. X

2.3 NOAA SCANNER OFFSET PROCEDURES

Halyo et al.⁵, determined the NOAA-9 and NOAA-10 ground count conversion coefficients and generated the corresponding offsets using the ground-calibration data reported by Hendricks^{4,7}. Data acquired by the NOAA-9 spacecraft in orbit indicated that ground and in-flight offsets were significantly different. The procedures used in the determination of the in-flight offsets for the ERBE NOAA satellites were developed by Mr. Lee Avis¹⁰ of the Atmospheric Sciences Division at the NASA Langley Research Center (LaRC). They consist, basically, of presuming that the ERBS satellite measurements are without error, and then making the necessary adjustments to the NOAA-9 data to make them equivalent to the ERBS data. The NOAA-9 and NOAA-10 offsets are produced only for scan positions 5 through 60, because of the difference in operational spacecraft altitudes.

2.3.1 NOAA-9 SCANNER OFFSET PROCEDURES

For selected days during the month, when the ERBS averaged radiance profile is approximately Lambertian and the ERBS and NOAA-9 satellite orbits intersect in darkness, averages of the differences in the two readings for each scan position (corrected for differences in satellite altitude) are determined. These "offsets" are called the "benchmark" offsets and represent the amount by which the NOAA-9 measured radiances must be corrected to produce the "corrected to ERBS" values. The NOAA-9 offsets for each day, or for a group of days, are determined by applying the "benchmark" offsets to the NOAA-9 readings for the "benchmark" day or days, averaging if more than one day is involved, and taking the difference between these "corrected to ERBS" NOAA-9 radiances and the measured NOAA-9 radiances on the day in question. The NOAA-9 scanner offsets, generated using the "Avis" method just described, are shown in Appendix B of this report. In the listings contained in Appendix B, there are occasional columns which are filled with asterisks. In those cases, there either were no data for the day in question, or the data were not reduced. As with the nonscanner, NOAA-9 scanner offsets begin in February 1985.

2.3.2 NOAA-10 SCANNER OFFSET PROCEDURES

In the case of the NOAA-10 satellite, scanner offsets are necessarily produced in a different manner than those for NOAA-9. There are two reasons for this: first, because of NOAA-10's terminator orbit, there are few intersections in darkness; and second, the NOAA-10 offsets have been found to be sensitive to scanner azimuth angle, which is alternately either 0 or 35 degrees. Therefore, to determine NOAA-10 offsets, an extension of Mr. Avis' procedures was developed by STX. The modified procedure uses the same software developed for the NOAA-9 to determine an average of all offsets for days which contain nighttime intersection data during the period under consideration (i.e., the period when the scanner azimuth angle remains fixed at either 0 or 35 degrees). These averaged data are then used as the NOAA-10 offsets for each day of the entire period. The NOAA-10 scanner offsets for 1986, which were generated using the "STX" method, are shown in Appendix C of this report.

2.4 SIGNIFICANT EVENTS

During the lifetimes of the three ERBE satellites, there have been periods of time when the satellites have not been functioning in their "normal" or Earth viewing mode. Some of these events, such as the bi-weekly internal calibrations and operations in the along-track (or pushbroom) mode were planned; others were not. A list of the most significant of these events follows.

2.4.1 SIGNIFICANT EVENTS: ERBS

The ERBS satellite was launched into a 57-degree inclination orbit on October 5, 1984, and became operational on November 1, 1984. During the month of January 1985, from the 16th to the 28th, and during the month of August 1985, from the 7th to the 14th, the ERBS scanner was operated in the along-track (or pushbroom) mode, as opposed to the normal cross-track (or whiskbroom) mode.

2.4.2 SIGNIFICANT EVENTS: NOAA-9

The NOAA-9 satellite was launched into a polar, Sun-synchronous, "noon/midnight" orbit on December 12, 1984. During the month of August 1985, from the 2nd to the 9th, the NOAA-9 scanner was operated in the along-track mode, as opposed to the normal cross-track mode.

Thus, for a period of 2 days, from August 7 to 9, 1985, both the ERBS and NOAA-9 scanners were functioning in an along-track mode.

2.4.3 SIGNIFICANT EVENTS: NOAA-10

The NOAA-10 satellite was launched into a polar, Sun-synchronous, "terminator" orbit on October 22, 1986. Because of the orientation of the Sun in relation to the NOAA-10 scanning plane in this terminator orbit, the scanner azimuth angle must be changed periodically to prevent scanning of the solar disk. From its launch until December 31, 1986, the NOAA-10 scanner azimuth angle remained fixed at 35 degrees.

3.0 NONSCANNING RADIOMETERS

The ERBE nonscanning sensor module is illustrated in Figure 2. The hemispherical shortwave dome, which is shown covering the active cavity in the illustration, is used only for the shortwave channels and is not present on the total instruments. Also, the distance separating the primary aperture and the field limiting aperture is much less on the WFOV instrument than on the MFOV. The complete design and method of operation for the nonscanners was described by Carman¹¹ and Luther et al.^{12,13}. The TRW ground calibration data for the ERBS, NOAA-9, and NOAA-10 nonscanners was documented by Fellner et al.^{14,15,16}. Halyo et al.⁵ designed, modeled, and validated count conversion equations to represent the TRW ground calibration data. They also produced the final count conversion coefficients for all nonscanning sensors. For the most part, nonscanner offsets were produced for every usable calibration day. The normal nonscanner calibration frequency was once every 2 weeks. As mentioned in the Introduction, NOAA-9 offsets start in February 1985, and NOAA-10 offsets start in October 1986.

3.1 NONSCANNER COUNT CONVERSION ALGORITHMS

The equations used in the determination of nonscanner offsets were developed by members of the ERBS Science Team, and are described by Halyo et al.⁵ They are used as follows:

TOTAL CHANNELS (WFOV & MFOV)

$$E_T = A_V \cdot V^2 + A_T \cdot T_T + A_R \cdot V_R^2 + B_T$$

SHORTWAVE CHANNELS (WFOV & MFOV)

$$E_{SW} = A_V \cdot V^2 + A_T \cdot T_T + A_R \cdot E_T + A_R \cdot V_R^2 + B_{SW}$$

The in-flight total channel count conversion coefficients, except for the B_T offset term, remain the same as the ground coefficients. The offset term, B_T , is recalculated using in-flight calibration data. However, because of degradation of the transmissivity of the Suprasil dome used to block longwave radiation from entering the active cavity of the shortwave channel, each count conversion coefficient for the shortwave channel is modified as described in the next paragraph. The shortwave offset term, B_{SW} , is then recalculated using the in-flight data.

3.1.1 DOME DEGRADATION CORRECTION

The transmissivity degradation caused by solar exposure of the dome is computed for each calibration day. The method of correction of the shortwave data to compensate for this dome degradation is accomplished by using the relationship:

$$A(t) = (s(t_0)/s(t)) * A = (C_0 / s(t)) * A$$

where: $A(t)$ = "corrected" in-flight shortwave coefficient

Figure 2. ERBE Nonscanner Sensor Module

$s(t_0)$ - measured solar irradiance on day 0
 $s(t)$ - measured solar irradiance on day t
 C_0 - offset calculated on day 0
A - ground coefficient for the term in question

The factor $(C_0/s(t))$ is sometimes referred to as the dome degradation factor. It is a number (normally greater than 1) which represents the amount by which the ground coefficient, A, must be increased to compensate for degradation of the dome. These comments apply to all "A" coefficients in the shortwave equation. For the coefficients and offsets listed in this document, the value of $s(t)$ was calculated from a second order fit to solar calibration data both before and after the data days. The offset term, B_{SW} , was computed by assuming zero shortwave energy present in the nighttime in-flight data. The procedures used for revising the coefficients and offsets are described by Paden et al.¹⁷.

3.2 GROUND OFFSETS

The TRW ground calibrations for the ERBE nonscanners are described by Fellner, et al.^{14,15,16}, at the TRW facility in Redondo Beach, California. The TRW calibration data were used by Information & Control Systems, Inc. (ICS), Hampton, Virginia⁵, to define count conversion coefficients. A summary of the applicable coefficients, which were generated through the combined efforts of ICS and NASA, is shown in Table 1. The radiometric fluxes, or "E" terms in the above equations, are calculated based on the coefficients, or "A" terms in Table 1, and the following variables:

V - Instrument output (volts)
 T_f - Field-of-view limiter temperature (degrees K)
 V_R - Calibration heater voltage (volts)

3.3 IN-FLIGHT OFFSETS

The ERBE Merge Subsystem, described by Stassi et al.³, was used to produce Instrument Validation Tape (IVT) for each calibration day in question. This tape was used as the source for nonscanner in-flight calibration data. Appendices G, H, and I contain figures depicting the offsets derived on the calibration days for the ERBS, NOAA-9, and NOAA-10 satellites, respectively. Monthly tables of nonscanner offsets, as they were used by the Merge Subsystem, are reproduced in their original memoranda format in Appendices J, K, and L, for the ERBS, NOAA-9, and NOAA-10 satellites, respectively.

3.3.1 TOTAL CHANNELS

Two data sets are used to independently determine total channel offsets (i.e., the B_T terms). These are referred to as "B-soak" and "internal cal." The "B-soak" data set is the set of 60 IVT records beginning 90 records before the "go to nadir" command preceding the elevation of the instrument to the internal sources

nadir" command preceding the elevation of the instrument to the internal sources for the internal calibration sequence. The "internal cal" data set is the data set comprised of records collected during the internal calibration sequence when both the Shortwave Internal Calibration Source (SWICS) and the calibration heater voltages are zero. Total channel offsets are independently determined from both of these data sets, using the temperature and voltage data supplied by the IVT records. If the "B-soak" offset is present, it is the preferred offset and is the final total channel offset. If the "B-soak" offset is not available, then the "Internal Cal" offset is used.

3.3.2 SHORTWAVE CHANNELS

Four data sets are defined for use in the independent determination of shortwave channel offsets. The "B-soak" and "internal cal" data sets, as described for the total channels; the "nighttime" data set; and the "solar cal" data set. The "nighttime" data set is the aggregate of all data records collected when the solar zenith angle is greater than a specified value. The specified value is normally 123 degrees. The "solar cal" data set is the collection of "space-look" records (about 24) following solar exposure while the instrument is returning to nadir. During the "nighttime" and "solar cal" periods, the incident shortwave flux is assumed to be zero. If there are data for the "nighttime" offset, this is the preferred offset. If not, then the second choice is the "internal cal" offset determined by using the IVT data (and using the SWICS temperature to determine the total channel flux reading, if it were observing the SWICS) adjusted by the appropriate "delta" (e.g., the fitted difference between the "nighttime" and the "internal cal" shortwave offsets). Failing either of these options, we then resort to using interpolated "nighttime" (first choice) or "internal cal" (second choice) data from the calibration days immediately preceding and succeeding the day in question. The "solar cal" offsets are not currently used. Deltas for shortwave channel correction to "nighttime" equivalents are determined from least squares linear fits to historical shortwave calibration data.

3.4 FINAL COUNT CONVERSION COEFFICIENTS

Appendices G, H, and I contain tables of nonscanner offsets for the ERBS, NOAA-9, and NOAA-10 satellites, respectively, for the years 1984, 1985, and 1986. These offsets were generated using data acquired on internal calibration days, which are shown in the plots in Appendices J, K, and L and are presented as they were used by the ERBE Merge Subsystem. For the most part, nonscanner offsets were produced for every useable calibration day, and the nonscanner internal calibration frequency was approximately once every 2 weeks. As mentioned in the Introduction, NOAA-9 offsets commence in February 1985, and NOAA-10 offsets commence in October 1986.

APPENDIX A

ERBS SCANNER OFFSET TABLES

APPENDIX A: ERBS SCANNER OFFSET TABLES

The following pages contain the ERBS scanner offset tables, both cross-track and along-track for the period from November 1984 until December 1986. As previously mentioned, the ERBS did not become operational until late October 1984.

During the periods from January 16 to 28, 1985, and from August 7 to 14, 1985, the ERBS spacecraft was operated in an along-track mode. Scanner offsets for these days are listed as "along-track" offsets. Offsets for all other days are listed as "cross-track" offsets. In reality, for all days in 1985, only one set of scanner (cross-track) offsets was used. The differences for each individual month were only in the offset for scan position 1 of the shortwave set.

The units used for all scanner offsets in these tables are watts per square meter per steradian.

	Table
ERBS Cross-Track Offsets, October 1984 - December 1985	A-1
ERBS Along-Track Offsets, January and August 1985	A-2
ERBS Scanner Offsets, January - December 1986	A-3

APPENDIX B

NOAA-9 SCANNER OFFSET TABLES

APPENDIX B: NOAA-9 SCANNER OFFSET TABLES

The following pages contain the scanner offset tables for the NOAA-9 spacecraft for the period from February to December 1986. As previously mentioned, the NOAA-9 did not become operational until late January 1985.

During the period from August 2 until 9, the NOAA-9 spacecraft was operated in the "along-track" mode. Scanner offsets listed for these days are those appropriate for the scanner operational mode on that day. Only one set of scanner offsets was used for each day.

The units used for all scanner offsets in these tables are watts per square meter per steradian.

	Table
February 1985	B-1
March 1985	B-2
April 1985	B-3
May 1985	B-4
June 1985	B-5
July 1985	B-6
August 1985	B-7
September 1985	B-8
October 1985	B-9
November 1985	B-10
December 1985	B-11
January 1986	B-12
February 1986	B-13
March 1986	B-14
April 1986	B-15
May 1986	B-16
June 1986	B-17
July 1986	B-18
August 1986	B-19
September 1986	B-20
October 1986	B-21
November 1986	B-22
December 1986	B-23

APPENDIX C

NOAA-10 SCANNER OFFSET TABLES

APPENDIX C: NOAA-10 SCANNER OFFSET TABLES

The following pages contain the scanner offset tables for the NOAA-10 spacecraft for the period from October to December 1986. Only one set of scanner offsets was used for each day. As previously mentioned, the NOAA-10 did not become operational until October 1986.

The units used for all scanner offsets in these tables are watts per square meter per steradian.

This page has been intentionally left blank

APPENDIX D

ERBS SCANNER OFFSET PLOTS

APPENDIX D: ERBS SCANNER OFFSET PLOTS

The plots in this section are standard "x,y" plots of scan position vs. offset for the total, longwave, and shortwave sensors. The scanner offsets for the ERBS are invariant over time; but they vary with scanner azimuth position, and, thus, there is a set for the "cross-track" (or "normal" mode) and a set for the "along-track" mode.

APPENDIX E

NOAA-9 SCANNER OFFSET SURFACE PLOTS

APPENDIX E: NOAA-9 SCANNER OFFSET SURFACE PLOTS

The following plots show the total, longwave, and shortwave NOAA-9 scanner offsets used during each applicable month of 1985 and 1986. The x-axis is in units of Earth-viewing scan position. The y-axis is in units of day-of-month, and the z-axis is in units of Watts/m²/steradian. Missing data are plotted as zero.

NOAA-9 NONSCANNER OFFSETS (MERGE)

APPENDIX K: NOAA-9 NONSCANNER OFFSETS (MERGE)

The tables of NOAA-9 nonscanner offsets in the following pages cover the period from February 1985 to December 1986.

Table

February 1985	K-1
March 1985	K-2
April 1985	K-3
May 1985	K-4
June 1985	K-5
July 1985	K-6
August 1985	K-7
September 1985	K-8
October 1985	K-9
November 1985	K-10
December 1985	K-11
January 1986	K-12
February 1986	K-13
March 1986	K-14
April 1986	K-15
May 1986	K-16
June 1986	K-17
July 1986	K-18
August 1986	K-19
September 1986	K-20
October 1986	K-21
November 1986	K-22
December 1986	K-23

APPENDIX L
NOAA-10 NONSCANNER OFFSETS (MERGE)

APPENDIX L: NOAA-10 NONSCANNER OFFSETS (MERGE)

The NOAA-10 satellite's nonscanner did not become operational until October 1986. The tables of NOAA-10 nonscanner offsets in the following pages begin with October 1986.

The units used for all nonscanner offsets in this table are watts per square meter.

	Table
October 1986	L-1
November 1986	L-2
December 1986	L-3

This page has been intentionally left blank
