SCIENCE REQUIREMENTS FOR A GLOBAL CHANGE TECHNOLOGY INITIATIVE ARCHITECTURE TRADE STUDY

by

John T. Suttles^{*}, Edwin F. Harrison^{*}, Gary G. Gibson[†], and Thomas G. Campbell[‡]

SUMMARY

Science requirements for a Global Change Technology Initiative (GCTI) Architecture Trade Study have been established by reviewing and synthesizing results from recent studies. A scientific rationale was adopted and used to identify a comprehensive set of measurables and their priorities. Spatial and temporal requirements for a number of measurement parameters were evaluated based on results from several working group studies. Science requirements have been defined using these study results in conjunction with the guidelines for investigating global changes over a time scale of decades to centuries. Requirements are given separately for global studies and regional process studies. For global studies, temporal requirements are for sampling every 1 to 12 hours for atmospheric and radiation parameters and 1 day or more for most Earth surface measurements. Therefore, the atmospheric measurables provide the most critical drivers for temporal sampling. Spatial sampling requirements vary from 1 km for land and ocean surface characteristics to 50 km for some atmospheric parameters. Thus, the land and ocean surface parameters have the more significant spatial variations and provide the most challenging spatial sampling requirements.

INTRODUCTION

Global observations of the physical parameters required to detect and quantify changes in global climate, composition of the atmosphere, surface properties, and the biosphere can only be accomplished using sophisticated instruments on orbiting spacecraft. Defining such a mission is a formidable task involving several essential elements. First, the overall goals of the effort must be defined and the associated science requirements established. Next, goals and

Table 2 shows the measurables and ESSC priorities for Earth science studies on the time scale of decades to centuries. The measurables are broken down into categories relating to the atmosphere, the Earth land and ocean surfaces, and the energy components of the solar and Earth radiation. While this list of measurables is widely accepted, the priorities are subject to debate. For example, the priority framework of the U. S. Global Change Research Program shown in table 3 (from ref. 5, a report by the Federal Coordinating Council on Science, Engineering, and Technology (FCCSET)), gives all the measurables in table 2 as high priority, but places much higher relative importance on clouds and water vapor than does the ESSC. At a recent meeting, the Investigator Working Group of the Earth Observing System (EOS) found substantial agreement with the priorities in table 3, but voiced the need for a relative measure of importance to give proper perspective to the separation between the highest and lowest priorities.

It seems prudent at this point to examine some parameters that are excluded by adopting the rationale stated above. To this end, the measurables for the time scale of thousands to millions of years are shown in table 4. Several items on this list warrant comment. Although given low priority by the FCCSET, two measurables were given the highest priority by the ESSC: seismic properties (including plate motions and deformations), and gravity and geoid. The seismic properties are presently being measured to high accuracy by in situ techniques supplemented by precise position information from the Global Positioning System (GPS). Some monitoring improvements can be achieved by the Geodynamic Laser Ranging System (GLRS). The gravity measurable is pertinent to this study, particularly as it relates to satellite position determination for analysis of altimetry measurements. This is an indirect requirement, and the GPS can provide the needed information. Therefore, based on the low priority for the adopted science rationale and the existing capabilities for these two measurables, we feel justified in not including these parameters. Also included on the list in table 4 is the lightning measurable, even though it was not included in the ESSC science discussions. Lightning has been included in several measurement system studies, however, so it was included for completeness. With regard to lightning, we have not found any specific scientific requirement for this measurement, and, therefore, it is not included in our study.

INITIAL MEASUREMENT REQUIREMENTS

Numerous scientific groups have undertaken to establish spatial and temporal requirements for Earth science measurements. Results of the most relevant studies are given in table 5 for temporal requirements and in table 6 for spatial requirements. The Science and Mission Requirements Working Group for the Earth Observing System (EOS) defined scientific requirements for a wide variety of measurements of atmospheric, radiative, and Earth surface parameters Based on current climate model characteristics, the spatial resolution for data products must be 100-250 km (horizontal) and have a vertical resolution equivalent to 9-17 pressure levels. Resolution requirements for instantaneous measurements should, therefore, be in the range of 10-25 km.

The best estimates of temporal resolution for data products range from less than 1 day to 1 month. For adequate temporal sampling, some variables such as cloud cover and associated radiation parameters require measurements across the entire diurnal cycle to avoid aliasing daily and longer-term variations. Other physical properties change at a much slower rate. Some examples are sea ice distribution and land surface properties.

Regional Process Studies are crucial to understanding the Earth as a system and to evolving improved models. These studies require the highest possible temporal and spatial resolutions, but are of limited time and space extent. They involve satellite, aircraft, and ground-based measurements used together in an intensive field study. Some of the important existing regional climate process studies are listed in table 8 for the Physical Climate System and for the Biogeochemical Cycles. These are the programs that must be continued and expanded upon in order to adequately understand regional processes and develop accurate models.

FINAL SCIENCE REQUIREMENTS

The requirements recommended for the GCTI Architecture Trade Study are shown in table 9. The requirements are given separately for Global Change Studies and Regional Process Studies. The requirements are to be interpreted as instantaneous measurement requirements, and the appropriate data products are given as a footnote. Parameters for which measurements over the diurnal cycle are critical are so noted. Where a range of values is given, the lower value is an ideal to provide an objective while the upper value is an adequate level or minimum requirement.

For Global Change Studies, temporal requirements are for sampling every 1 to 12 hours for atmospheric and radiation parameters and 1 day or more for most Earth surface measurements. For temporal variations, the most rapidly changing parameters are those related to the Earth's atmosphere. For this reason, these measurables provide the most critical drivers for temporal sampling. Spatial sampling requirements vary from 1 km for land and ocean surface characteristics to 90 km for atmospheric parameters. Thus, the land and ocean surface parameters have the more significant spatial variations and provide the most challenging spatial sampling requirements.

•	CONCEPTUAL AND NUMERICAL MODELS
	THOUSANDS TO MILLIONS OF YEARS - EARLY EARTH, CORE AND MANTLE, PLATE-TECTONICS, AND SOLAR-DRIVEN
	DECADES TO CENTURIES - PHYSICAL SYSTEMS (ATMOSPHERE, OCEANS, LAND SURFACES), BIOGEOCHEMICAL CYCLES, WATER CYCLE
•	OBSERVATIONAL REQUIREMENTS
	REMOTE SENSING VS. IN SITU OBSERVATIONS
	INSTANTANEOUS MEASUREMENTS VS. ANALYZED DATA PRODUCTS
•	SCIENTIFIC STUDIES
	GLOBAL VARIABLES (SURVEYS)
	PROCESSES (CASE STUDIES)
