NOTICE

The invention disclosed in this document resulted from ¹⁴⁸ research in aeronautical and space activities performed under programs of the National Aeronautics and Space Administration. The invention is owned by NASA and is, therefore, available for licensing in accordance with the NASA Patent Licensing Regulation (14 Code of Federal Regulations 1245.2).

To encourage commercial utilization of NASA-owned inventions, it is NASA policy to grant licenses to commercial concerns. Although NASA encourages nonexclusive licensing to promote competition and achieve the widest possible utilization, NASA will consider the granting of a limited exclusive license, pursuant to the NASA Patent Licensing Regulations, when such a license will provide the necessary incentive to the licensee to achieve early practical application of the invention.

Address inquiries and all applications for license for this invention to NASA Resident Office-JPL, NASA Patent Counsel, Mail Code 180-801, 4800 Oak Grove Dr., Pasadena, CA 91103. Approved NASA forms for application for nonexclusive or exclusive license are available from the above address.

Date: July 18, 1989

AWARDS ABSTRACT

The present invention relates to superconductive devices, and, more particularly, to such devices utilizing superconductor-insulator-superconductor tunnel junctions.

In accordance with the present invention, edge-geometry NbN/MgO/NbN superconducting tunnel junctions are provided. The use of an edge geometry allows very small junction areas (0.01 to 1 μm^2) to be obtained, while the all-NbN electrodes permit operation at 8 to 10K, with a potential maximum operating frequency above 1 THz. Fig. 1 illustrates a perspective view of the finished device, while Fig. 3 illustrates a top plan view thereof. Figs. 2a-d illustrate the sequential steps in fabricating the device. The edge-geometry tunnel junction of the invention comprises a base electrode 10 of a patterned aluminum metal layer 12 formed on a NbN layer 14, formed on an insulating substrate 16. The NbN electrode is preferably deposited with the insulating substrate maintained at about 250° to 500° C for improved quality of the electrode. The aluminum layer is patterned to provide an edge 18. A layer 20 of Al_2O_3 is then formed and patterned to overlap the edge 18 of the aluminum layer 12. The patterned Al_2O_3 is used to define an edge 22 in the NbN layer 14. A very thin layer (5 to 30 Å) of MgO is then blanket-deposited everywhere, including on the edge 22. Next, a counter-electrode contact 26 comprising a layer 28 of NbN is formed on the substrate, overlapping the MgO-coated edge of the first NbN layer. The portion of the counter-electrode overlapping the edge 22 is patterned to provide a small area contact 30 with the MgO-coated edge of NbN. Fig. 4 presents the current-voltage of a typical 0.1 x 1 μm^2 junction of the invention with a current density of 1 x 10⁴ A/cm², a junction resistance of 325 Ω , and a gap sum of 4.9 mV. For this junction, the value of V_n ($V_n = I_c R_{jg}$) is 61 mV at 3 mV and 4.2K, and the gap spread is approximately 0.7 mV. These junction parameters are comparable to parameters for trilayer NbN/MgO/NbN junctions of similar current density.

The NbN/MgO/NbN edge junction devices of the invention are suitable for superconductor-insulator-superconductor (SIS) mixers operating in the 300 to 500 GHz range.

EDGE GEOMETRY SUPERCONDUCTING TUNNEL JUNCTIONS
UTILIZING AN NbN/MgO/NbN THIN FILM STRUCTURE

Origin of the Invention:

10

The invention described herein was made in the performance of work under a NASA contract, and is subject to the provisions of Public Law 96-517 (35 U.S.C. 202) in which the Contractor has elected not to retain title.

Technical Field:

15

The invention relates to superconductive devices, and, more particularly, to such devices utilizing superconductor-insulator-superconductor tunnel junctions.

Background Art:

20

25

30

Since their first use as quasiparticle mixers, SIS (superconductor-insulator-superconductor) tunnel junctions have become the lowest noise broad band mixers from 30 GHz to 760 GHz. Sensitivity of these mixers has approached the quantum limit ($h\nu$ power per unit bandwidth) at frequencies up to 110 GHz. A comprehensive theory of these devices has been developed which predicts excellent performance for SIS tunnel junctions as mixers well below millimeter wavelengths. However, actual development of submillimeter SIS mixers has been limited by currently used lead alloy junctions. Lead alloy junctions give excellent mixer results in the near-millimeter wave region, but have poor chemical, thermal, and electrical stability because lead is a soft, low melting point material.

35

For high speed switching or high frequency detection applications utilizing SIS tunnel junctions, devices with very thin tunnel barriers and correspondingly high current

densities (J_c) are required. This constraint arises from the fact that the junction resistance decreases exponentially with decreasing barrier thickness, while the capacitance only increases linearly as the barrier thickness is reduced. Thus, the maximum operating frequency, which is inversely proportional to the resistance-capacitance (RC) product, can be increased by reducing the tunnel barrier thickness. Practical applications also require that the junction resistance be large enough (typically $\geq 50 \Omega$) to allow impedance matching to external circuits. Because the RC product is independent of area while the resistance increases as the junction area is decreased, this requirement can be met by fabricating small cross-sectional area tunnel junctions. To obtain junctions with adequate resistances and frequency response above 200 to 300 GHz, it is necessary to produce junctions with areas less than approximately $1.0 \mu\text{m}^2$, which are difficult to achieve using conventional photolithography.

One useful technique for fabrication of small area tunnel junctions utilizes an edge geometry to achieve very small junction areas without resorting to high resolution lithography. Superconducting edge junctions have been fabricated in a variety of materials systems, including Pb/Sn, PbIn/Pb, Nb/Pb-alloys, and NbN/Pb. However, relatively little work exists on all-refractory edge junctions, with only brief reports on Nb/Nb₂O₅/Nb and NbN/Si/NbN junctions.

A recent patent by J. J. Talvaccio et al (U.S. Patent 4,768,069) discloses a planar geometry of NbN/MgO-CaO/NbN. The substrate is heated to about 700°C to sputter-deposit the first NbN electrode and the oxide barrier layer.

For most practical high frequency applications, it is also necessary to fabricate superconducting tunnel junctions with high quality current-voltage (I-V) characteristics. In this case "high quality" means low subgap leakage coupled with a current rise at the gap sum which is narrow on the scale of the operating frequency. It is also highly desirable to utilize junction materials which are

resistant to chemical attack and static discharges. In summary, then, high frequency applications require rugged, small area tunnel junctions with high current density, high quality I-V characteristics. Such characteristics are not achieved with the prior art teachings.

Statement of the Invention:

Accordingly, it is an object of the invention to provide a superconducting device with a very small junction area.

It is another object of the invention to provide an edge-geometry superconducting tunnel junction device utilizing NbN electrodes and an MgO tunnel barrier.

It is still another object of the invention to provide a process for fabricating an edge-geometry superconducting tunnel junction device utilizing NbN electrodes and an MgO tunnel barrier.

In accordance with the invention, edge-geometry NbN/-MgO/NbN superconducting tunnel junctions are provided. The use of an edge-geometry allows very small junction areas to be obtained, while the all-NbN electrodes permit operation at 8 to 10K, with a potential maximum operating frequency above 1 THz.

Also in accordance with the invention, a novel technique for producing very small area tunnel junctions with conventional photolithography uses an edge geometry to define the junction area. Edge geometry tunnel junction fabrication relies on the formation of a tunnel barrier on the exposed edge of a superconducting film. The junction is completed by deposition and patterning of a superconducting counterelectrode. Because the top surface of the base superconductor is covered by a thick insulator, the contact area between the counterelectrode and the base electrode is determined by the thickness of the base layer and the width of the top electrode tip. Because the base electrode thickness can easily be in the 0.1 μm range, junction areas on the order of 0.1 μm^2 are readily attainable using conven-

tional photolithography at the 1 μm resolution level. A somewhat more subtle advantage of the edge geometry is that the in-line structure minimizes current-crowding effects that can lead to electrode transitions in high-current-density, planar-geometry junctions.

This is believed to be the first successful fabrication of edge-geometry tunnel junctions utilizing two niobium nitride electrodes with a magnesium oxide tunnel barrier. The combination of an all-NbN electrode structure with an MgO barrier results in very rugged tunnel junctions with very high quality I-V characteristics and junction areas as small as 0.1 μm^2 . In addition, the process described below has produced NbN/MgO/NbN edge junctions with current densities up to 1.5×10^4 A/cm², which is sufficient for junction operation at frequencies in the 500 GHz range. These devices have demonstrated excellent performance in preliminary receiver tests at 205 GHz, yielding receiver noise temperatures as low as 380K.

Brief Description of the Drawings:

Fig. 1 is a perspective view of an edge-geometry superconducting tunnel junction utilizing an NbN/MgO/NbN thin film structure in accordance with the invention;

Figs. 2a-d are cross-sectional views depicting the edge junction process of the invention at various stages;

Fig. 3 is a schematic top plan view of the thin film structure; and

Fig. 4 is a plot, on coordinates of current and voltage, depicting the I-V characteristics of a 0.1 x 1 μm^2 NbN/MgO/NbN edge junction, with the vertical scale in 10 μA /division and the horizontal scale in 2 mV/division.

Detailed Description of the Invention:

The NbN/MgO/NbN thin film structure is depicted in Fig. 1. The edge-geometry tunnel junction comprises a base electrode contact 10 of a patterned aluminum metal layer 12 formed on a NbN layer 14, formed on an insulating sub-

strate 16. The aluminum layer 12 is patterned to provide an edge 18. A layer 20 of Al_2O_3 is then formed and patterned to overlap the edge 18 of the aluminum layer 12. The patterned Al_2O_3 is used to define an edge 22 in the NbN layer 14. A very thin layer of MgO 24 is then deposited on the edge 22. Next, a counterelectrode contact 26 comprising a layer 28 of NbN is formed on the substrate, overlapping the MgO-coated edge 22 of the first NbN layer 14. The portion of the counter-electrode overlapping the edge 22 is patterned to provide a small area contact 30 with the MgO-coated edge of NbN.

The basic NbN/MgO/NbN edge junction process is described below. The key fabrication steps are shown in Figs. 2a-d. While specific parameters are given, it should be understood that these are exemplary only, and that other process parameters which provide the described result are within the scope of the invention.

The initial process in edge junction fabrication is D.C. magnetron sputter deposition of the base NbN layer 14 ($\approx 0.1\mu\text{m}$) and an Al overlayer 12, typically on a sapphire substrate 16 (Fig. 2a). The substrate 16 conveniently comprises 0.625 inch square, 0.010 inch thick, unoriented sapphire substrates, although other insulating substrates, such as silica (e.g., SiO_2 on Si, or quartz) and magnesia, may be used. In the case of silica, a buffer layer MgO of about 200 to 500 Å thick, helps the growth of the NbN electrode. Such a buffer layer is formed by sputter deposition of MgO in an Ar- N_2 atmosphere.

NbN is reactive-DC sputtered from a Nb target in an Ar- N_2 mixture using a 2 inch diameter planar magnetron sputter gun. Ar flow rates are 20 to 150 sccm, and Ar partial pressures are 13.5 mTorr. N_2 flow rates are typically 2 to 15 sccm. Sputtering currents are held fixed at 0.50 Amps, and the target to substrate distance is 2.75 inches. The NbN layer 14 is formed to a thickness of about 100 to 10,000 Å, and preferably from about 0.1 to 0.2 μm .

During the NbN deposition, the insulating substrate 16

is preferably heated to about 250° to 500°C, and more preferably from about 300° to 450°C. The heating is believed to promote the formation of high quality NbN near the substrate surface, which is essential for obtaining edge junctions with low subgap leakage and sharp gap edges. Such heating tends to result in a more uniform composition through the thickness of the NbN layer. However, moderate quality junction fabrication is also possible on unheated substrates.

The substrate 16 must be heated to about 300°C in order to obtain the desired substantially uniform composition throughout the thickness of the NbN layer. Heating to more than about 500°C produces poor quality edge junctions, due to substrate interactions with the NbN layer.

The Al layer 12 is next formed, using an Al target and an Ar flow rate and partial pressure as above. The Al layer 12 is formed to a thickness of about 0.6 μm , which is appropriate for a base NbN layer of about 1,000 to 1,500 Å.

It will be noted that the aluminum layer thickness is chosen so that at least a small amount of Al remains after the ion milling process. Thus, the thickness of this layer is determined by the thickness of the base NbN layer which sets the required milling time. Any other metal layer or combination of metal layers can be used instead of aluminum, provided that these layers can be selectively etched relative to the base NbN layer, and provided that such layers survive the ion milling process and are chemically compatible with NbN.

One such alternate process which has been implemented by the inventors utilizes a metal bilayer of a thin Al film (≈ 100 to 250 Å) deposited on the base NbN layer and overlaid by a second NbN layer with a thickness typically 500 to 1,000 Å greater than the base NbN layer. In this case, the top NbN layer is photolithographically patterned using the conventional CF_4/O_2 RIE (reactive ion etch) dry etch down to the thin Al film, which serves as an etch stop.

The Al layer is then wet-etched and the process proceeds as normal. This modification to the conventional process minimizes the chemical interaction between Al and NbN which can sometimes occur.

5 Following the metal depositions, the Al layer 12 is patterned using photolithography and wet etching. The aluminum layer ultimately serves as the edge junction base electrode contact 10. An edge 18 is defined at one end of the patterned aluminum layer 12.

10 A layer 20 of Al_2O_3 is then deposited everywhere, such as by electron beam evaporation, to a thickness of about 0.1 to 0.8 μm (as determined by the base NbN thickness). The Al_2O_3 thickness is determined by the requirement that an insulating layer remain on top of the base NbN layer after
15 the ion-milling edge-cutting process is complete. Al_2O_3 is typically used because it has a low ion milling rate, but any other insulator could be used, provided that it could be patterned appropriately by lift-off or etching in a thick enough layer to serve as an ion milling mask. Bi-
20 layers of insulators could also be used with the same restrictions. Junctions have been fabricated using bilayers of SiO_2 over Al_2O_3 , as well as with single layers of SiO_2 .

 The Al_2O_3 layer 20 is patterned via liftoff to provide a milling mask, as shown in Fig. 2b.

25 The patterned Al_2O_3 and Al layers 20, 12 shown in Fig. 2b serve as ion milling masks to protect the underlying NbN layer 14 during the edge-cutting step. A 500 eV Ar ion beam is used to define the NbN edge 22, shown in Fig. 2c. The resulting edge is inherently sloped at about 60° from
30 the horizontal plane (about 30° off normal). Immediately following the edge milling, a lower energy (80 to 150 eV) Ar ion beam cleaning step is done to remove any surface damage caused by the high energy edge definition process. The use of low energy ions minimizes the thickness of the
35 damaged surface layer, which is especially important for a short coherence length material like NbN.

 After the edge cleaning, the MgO tunnel barrier 24 and

NbN counterelectrode layer 28 are deposited, using RF magnetron sputtering for the MgO and DC magnetron sputtering for NbN.

5 MgO is RF sputtered from pressed MgO targets using a 2 inch diameter planar magnetron sputter gun. Ar flow rates are 20 to 150 sccm, and the Ar pressure is 10.0 mTorr. MgO is deposited intermittently by rotating the substrate over the sputter gun; this provides better thickness control and helps promote uniformity in the typically 10 1 nm thick MgO barrier 24. Following the MgO deposition, the barrier is exposed to a brief oxygen plasma discharge.

The MgO barrier film is blanket-deposited to a thickness of about 5 to 30 Å and, more preferably, to a thickness of about 5 to 20 Å. At least about 5 Å (about one 15 monolayer) is required for high quality tunneling barriers, while thicknesses greater than about 30 Å defeat tunneling.

The NbN counter-electrode layer 28 is formed, using the same process as above for the deposition of NbN layer 14, except that the substrate is not intentionally heated. 20 The NbN counter-electrode was also coated with an evaporated 300 Å gold layer (not shown) to aid in making contact to the junctions.

Finally, the counterelectrode is patterned using standard photolithography and reactive ion etching in a CF₄/O₂ 25 gas mixture (Fig. 2c and 3).

Using the above process, edge junctions with areas ranging from 0.1 to 0.8 μm² have been fabricated. These are the first reported NbN/MgO/NbN edge junctions. The areas of the edge junctions may range from about 0.01 to 1 30 μm².

Figure 4 presents the current-voltage characteristics of a typical 0.1 x 1 μm² junction with a current density of 1 x 10⁴ A/cm², a junction resistance of 325 Ω, and a gap sum of 4.9 mV. For this junction, the value of V_n (V_n = I_cR_{sq}) is 35 61 mV where R_{sq} is measured at 3 mV and 4.2K, and the gap spread is approximately 0.7 mV. The junction parameters obtained for these all-NbN edge junctions are superior to

parameters for prior art trilayer NbN/MgO/NbN junctions of similar current density as described in U.S. Patent 4,768,069. In particular, the edge junctions of the invention show lower subgap leakage than the devices of U.S. Patent 4,768,069 for junctions of a given current density, as evidenced by the high values of V_g (at 3 mV) obtained for the edge junctions of the invention.

The present edge junction characteristics are suitable for SIS mixer testing in the 300 to 500 GHz range.

Thus, there has been disclosed a superconducting tunnel junction device comprising a tunnel junction region comprising an MgO film sandwiched between two NbN electrodes, the MgO film being formed on a portion of an edge of one of the electrodes. It will be readily apparent to those skilled in this art that various changes and modifications of an obvious nature may be made. All such changes and modifications are considered to fall within the scope of the invention, as defined by the appended claims.

EDGE GEOMETRY SUPERCONDUCTING TUNNEL JUNCTIONS
UTILIZING AN NbN/MgO/NbN THIN FILM STRUCTURE

ABSTRACT OF THE DISCLOSURE

5

An edge defined geometry is used to produce very small area tunnel junctions (30) in a structure with niobium nitride superconducting electrodes (14, 28) and a magnesium oxide tunnel barrier (24). The incorporation of an MgO tunnel barrier with two NbN electrodes results in improved current-voltage characteristics, and may lead to better junction noise characteristics. The NbN electrodes are preferably sputter-deposited, with the first NbN electrode deposited on an insulating substrate maintained at about 250° to 500°C for improved quality of the electrode.
