SUMMARY

Tabulations and plots are presented of boundary-layer velocity and flow-direction surveys from wind-tunnel tests of a large-scale (0.90 m semispan) model of the NASA/Lockheed Wing C. This wing is a generic, transonic, supercritical, highly three-dimensional, low-aspect-ratio configuration designed with the use of a three-dimensional, transonic full-potential-flow wing code (FLO22). Tests were conducted at the design angle of attack of 5° over a Mach number range from 0.25 to 0.96 and a Reynolds number range of 3.4×10^6 to 10×10^6. Wing pressures were measured at five span stations, and boundary-layer surveys were measured at the midspan station. The data are presented without analysis.

INTRODUCTION

Ames Research Center and the Lockheed-Georgia Company conducted a joint computational/experimental research program to obtain detailed pressure-distribution and boundary-layer data on a generic model of a modern advanced-technology wing. This program was to contribute to the current efforts to validate inviscid and viscous numerical codes. The wing was designed using a three-dimensional, full-potential-flow, transonic wing code (FLO22), and an optimization routine. A highly three-dimensional, highly swept, highly twisted, low-aspect-ratio wing with supercritical airfoils was one configuration selected for study. The wing was designed for moderate aft loading, mild shock waves, and a mild pressure recovery. The result was a highly optimized wing (designated Wing C) designed for unseparated flow at a design Mach number of 0.85, and a design lift coefficient of about 0.5, at an angle of attack of about 5°.

As a part of the cooperative effort, Lockheed Georgia tested a small-scale 0.26 m semispan model of Wing C in the Lockheed-Georgia Compressible Flow Wind Tunnel at a Reynolds number of 10 million, based on the mean aerodynamic chord. In addition, they designed and tested two other small-scale wing models: a transport-type wing, and a fighter-type wing (designated Wings A and B). The surface pressures were measured on both the wing and on the tunnel wall for comparison with the calculations. The small-scale data are published in reference 1, and comparisons of the small-scale measurements with several 3-D transonic inviscid codes are presented in references 2 and 3. Boundary-layer thickness and skin-friction predictions are also presented in reference 4 for several standard 3-D transonic boundary-layer codes.

At Ames Research Center a large-scale (0.90 m) semispan model was built to obtain thicker boundary layers for ease of measurement. The surface pressures were

measured at five span stations. The surface flow patterns were photographed using oil-flow visualization. The boundary-layer velocity and flow direction surveys were obtained at the mid-semispan station, using a three-hole flow-direction probe at 0.218%, 0.350%, and 0.421% chord. Two-dimensional boundary-layer velocity surveys were also obtained with a laser velocimeter at 0.900% chord and also at the trailing edge. Data were obtained at the design angle of attack of 5° over a Mach number range of 0.25 to 0.96, and a Reynolds number range of 3.4×10^6 to 10×10^6.

A description of the wing design and an analysis of selected pressure distributions and interpreted oil-flow studies are presented in references 5 and 6. Early in the design stage, it was expected that a low-aspect-ratio wing with a large leading-edge sweep would have significant three-dimensional boundary-layer flow, even at unseparated-flow conditions. However, the analysis in references 5 and 6 shows that this was not the case for this wing, except near the leading edge. Oil-flow patterns indicated that boundary-layer flow angles were less than 10° behind the leading edge, so that boundary-layer measurements for Wing C would not be a substantial test of 3-D boundary-layer codes for large flow angles at unseparated-flow conditions. However, these data are useful because 3-D boundary-layer codes could be partially validated for small flow angles with these data. Moreover, one of the attributes of the present set of boundary-layer measurements is the set of laser velocimeter surveys obtained at the trailing edge (it is in this region that data are lacking in previous wing tests). This data report is to present tabulations and plots on microfiche film of the boundary-layer measurements for Wing C.

The author wishes to acknowledge that the laser velocimeter measurements were obtained by Dennis Johnson and Edward Schairer of Ames Research Center.

NOMENCLATURE

The conventional symbols are listed (if used herein) followed by the computer symbol used in the tabulated results. The test conditions are presented first, followed by wing geometry, boundary-layer pressure-probe surveys, boundary-layer integral characteristics, and laser velocity surveys.

Symbol	Computer Symbol	Definition
		Test Conditions
α	ALPHA	angle of attack, deg
M_∞	MACH	free-stream Mach number
p_∞	P	free-stream static pressure, psf
p_t	PT	free-stream total pressure, psf

q	Q	free-stream dynamic pressure, psf
$Re/\bar{c}$	RN/L	free-stream unit Reynolds number, M/ft
Re	RN	Reynolds number based on $\bar{c}$, M
t	TR	free-stream static temperature, °R
t_t	TTR	free-stream total temperature, °R

Wing Geometry

b/2	B/2	wing semispan
c		local wing chord
$\bar{c}$	MAC	wing mean aerodynamic chord, $(2/S) \int_0^1 c^2 \, d(n)$
c_R	CR	root chord
c_T		tip chord
n	n	nondimensional spanwise distance from wing root, fraction of semispan
S/2		area of semispan wing model
x	X	chordwise distance rearward of leading edge
z		spanwise distance outboard of wing root

Boundary-Layer Pressure-Probe Surveys

	TST-P-TN	tabulation identification: test-phase tunnel 356-1-66
	RUN:SEC	tabulation identification: run:sequence
	Conf	configuration number (Table 2)
	N	number of data points in B.L. survey
	W	I.D. number of orifice closest to B.L. survey station (ref. 6)
M	ML	local Mach number
p_C	PC	flow-direction-probe pressure: center tube

p_L	PL	flow-direction-probe pressure: left tube
p_R	PR	flow-direction-probe pressure: right tube
p_w	PW	wall (surface) static pressure on wing at boundary-layer survey station from pressure-distribution measurements (ref. 6)
$p_{t,2}$	PT2	probe pitot pressure for PSI = 0, calculated from Y6 and PSI
R		local gas constant
V	V	local resultant velocity
u	U	local velocity component in chordwise (streamwise) direction (u plane, fig. 7)
u_1	U1	local velocity component in direction of streamline at edge of boundary layer (u_1 plane, fig. 7)
w	W	local crossflow velocity component, normal to u
w_1	W1	local crossflow velocity component, normal to u_1
x	X	distance behind wing leading edge
y, in.	Y	vertical height of probe above wing surface, in.
y, cm	YCM	vertical height of probe above wing surface, cm
Y4	Y4	probe-differential-pressure calibration function for flow-direction angle, (PR - PL)/{PC - [(PR - PL)/2]}
Y6	Y6	probe-pitot-pressure calibration function for effect of flow angle, (PC - PT2)/{PC - [(PR - PL)/2]}
Y10	Y10	probe-Mach-number calibration factor, (PR + PL)/2PC
Y11	Y11	alternative probe-Mach-number calibration factor, P/PC
Y12	Y12	alternative probe-Mach-number calibration factor, 2P/(PR + PL)
	RHO	local density
	MUE	local dynamic viscosity

	NU	local kinematic viscosity
	DELU	delta U: B.L. thickness derived from velocity profile from height at which U/UE = 0.995
	PSI	local flow-direction-probe angle, calculated from Y4, positive for PR > PL Flow direction from the right is positive for which the flow angle is inclined in the outboard direction
	DPSI	delta PSI: differential flow-direction angle (PSI - PSIE), positive when angle is inclined in an outboard direction

Boundary-Layer Integral Characteristics

d^*	DSTAR	delta star: boundary-layer displacement thickness from integration in u plane
d_1^*	DSTAR1	delta star-1: boundary-layer displacement thickness from integration in u_1 plane
θ	THETA	boundary-layer momentum thickness from integration in u plane
θ_1	THETA1	boundary-layer momentum thickness from integration in u_1 plane
H	H	boundary-layer shape factor in chordwise plane, d^*/θ
H_1	H1	boundary-layer shape factor in u_1 plane, d/θ_1^*
Re_θ	RTH	local momentum-thickness Reynolds number, based on θ
$Re_{\theta,1}$	RTH1	local momentum-thickness Reynolds number, based on $\theta 1$

Laser Velocity Surveys

r	resultant velocity measured with a pair of laser beams incident at mean angle $+\beta$, $u \cos \beta + w \sin \beta$
s	resultant velocity measured with a pair of laser beams incident at mean angle $-\beta$, $u \cos \beta - w \sin \beta$
u	velocity component in the chordwise direction
v	velocity component in the vertical direction (normal to the wing reference plane)
w	velocity component in the crossflow direction, positive outboard

β		mean angle of incidence of laser beams measured in the wing reference plane from the crossflow direction, positive when inclined downstream

Superscripts: (laser velocimeter measurements only)

$( )'$		fluctuating quantity, e.g., $u = \bar{u} + u'$
$(\bar{})$		time averaged quantity
$\langle' \rangle$		rms value of quantity

Subscripts:

1	$( )_1$	boundary-layer characteristics in u_1-plane (fig. 7)
e	$( )_E$	conditions at edge of boundary layer
L	$( )_L$	lower surface
U	$( )_U$	upper surface
∞	$( )_{FS}$	free-stream conditions

TEST FACILITY

The Ames 6- by 6-Foot Transonic/Supersonic Wind Tunnel was chosen because the allowable model size and the tunnel operational characteristics were suitable for boundary-layer research. The tunnel is a variable pressure, continuous-flow facility. The nozzle used is an asymmetric sliding-block type that permits a continuous variation of Mach number from 0.25 to 2.3. The test section has a slotted floor and ceiling having 6% porosity with provisions for boundary-layer removal using uniform suction.

MODEL DESCRIPTION

Figure 1 shows sketches of the three wings designed in the collaborative program with the Lockheed-Georgia Company: Wing A, a high-aspect-ratio transport configuration; Wing B, a moderate-aspect-ratio fighter configuration; and Wing C, a highly three-dimensional, low-aspect-ratio, generic research configuration. Figure 2 shows the geometric details of Wing C which is the subject of the present investigation. Wing C is not intended to represent any existing wing. The geometry was selected to be consistent with the requirements that the wing have a large leading-edge sweep angle (45°) in order to develop a 3-D boundary layer, and a large

mean chord so as to develop a thick, easily measured boundary layer. The wing was then designed using modern computational fluid dynamic methods, which incorporated supercritical wing technology.

Wing C was designed for the present study by R. Hicks of ARC and B. Hinson of Lockheed-Georgia using the FL022 computer code. The selected design condition was a Mach number of 0.85, and a lift coefficient of about 0.5 occurring at an angle of attack of 5°. (Further details are given in refs. 5 and 6.)

The final theoretical root and tip airfoil coordinates for Wing C are listed in table 1. Typical calculated inviscid pressure distributions from the FL022 code were presented in references 3, 5, and 6. Lockheed Georgia estimated that the three-dimensional boundary-layer thickness effects did not influence the design pressure distributions (ref. 3).

For the present test, a large-scale semispan (reflection plane) wing model was designed to be mounted on the tunnel wall (fig. 3). Wing-root flow disturbances were not felt to be a problem because the flow would not be separated at the design condition. Also, it was not intended to test this model at high angles of attack where extensive separation would be present. A wing semispan of 0.90 m (close to one half of the test-section width), was selected as a suitable size, giving a test-section blockage ratio of 1.3%. This is considered to be a reasonable value to avoid severe tunnel-wall lift-interference effects. The wing was constructed from 17-4 PH stainless steel to minimize dynamic-load deflections and corrosion. The measured construction tolerance was ±0.12 mm (0.005 in.) over most of the surface and ±0.24 mm (0.010 in.) at the extremities.

INSTRUMENTATION AND ACCURACY

The instrumentation consisted of static-pressure orifices in the wing and turntable; a 3-hole, flattened tip, "cobra-head," boundary-layer flow-direction probe; a laser velocimeter; and one vertical accelerometer mounted in the wing tip.

The pressure instrumentation consisted of 229 static-pressure orifices installed at five spanwise stations (n = 0.1, 0.3, 0.5, 0.7, and 0.9), 203 orifices on the tunnel-wall turntable, and three pressures for the 3-hole "cobra-head" probe. Wing-orifice locations and the complete set of pressure measurements were tabulated in reference 6. These pressures were measured using conventional pressure-scanning valves. The self-calibrating feature of the scanning valves provided an accuracy of about one-quarter percent of the full scale of the ±8.62 N/sq cm (±12.5 psi) transducers, corresponding to about ±0.01 in. pressure coefficient. Each survey of surface and probe pressures required about 4 min. In particular, the probe-pressure survey incorporated a programmed 3-sec lag to account for pressure-line equilibrium.

Tunnel test Mach numbers were computed from wall-static and tunnel-total pressures to an accuracy of about ±0.002. Tunnel Mach-number unsteadiness was

controlled within about ±0.003 at $M = 0.85$ to 0.95, and smaller at lower Mach numbers. Tunnel-static pressure was measured on the tunnel wall 2.4 wing-root-chord lengths ahead of the wing-root leading edge. The angle of attack was set manually by rotating the wall turntable and by setting the angle to an accuracy of about ±0.03°.

The boundary-layer traversing mechanism was mounted below the wing to eliminate interference on the upper-surface pressures (fig. 4). The mechanism moved a pylon through a slot in the wing with a vertical traverse of about 5 cm. The probe support was attached to the top of the pylon (fig. 5(a)). Probe height was varied by a stepper motor that drove a ball-screw drive shaft attached to the pylon. The stepper motor was actuated by a controller, programmed for 48 automatic steps. The probe height was indicated by a linear-strip potentiometer, accurate to about 0.05 mm. An electrical circuit indicated when the probe touched the wing surface, at which time the probe height was set to zero. With the probe-drive mechanism attached to the wing, the probe-height readings were steady and repeatable within about 0.07 mm. The 3-hole probe was made from 1.0-mm diam tubes soldered together with their tips flattened to 0.15-mm height and a 0.07-mm opening (fig. 5(b)). The three pressure tubes were connected through the wing to a scanning valve outside the tunnel.

A 3-component laser-velocimeter system was set up outside the tunnel window. Owing to equipment problems, only a few 3-component velocity measurements were successfully obtained at $M = 0.70$. However, 2-component data were obtained that are useful since the local surface-flow-direction angle was shown by oil-flow measurements to be small.

TEST CONDITIONS AND PROCEDURES

Wing and boundary-layer-probe pressures were measured at Mach numbers from 0.25 to 0.96, and Reynolds numbers from 3.4×10^6 to 10×10^6. Since the angle of attack was not remotely controllable, the investigation was conducted at the design angle of attack of 5°. The test conditions are listed in table 2. Boundary-layer trips were installed on the wing using sifted glass spherules at 4.5% chord, and sublimation flow-visualization tests were made to determine an effective size. Two final trip sizes were selected: 0.16-mm (No. 100 mesh) trips were used on the lower surface and outboard of 60% span on the upper surface; 0.23-mm (No. 70 mesh) trips were used on the upper surface over the inboard 30% span. Oil-flow tests were made at several Mach numbers and Reynolds numbers using fluorescent oil (ref. 6).

The 3-hole flow-direction probe was calibrated using a probe support attached to the sting support system for flow angles up to 30° and Mach numbers up to 2.0 (local Mach numbers were supersonic). Probe pressures were measured at the midspan station at $x/c = 0.218$, 0.350, and 0.421 and Mach numbers from 0.5 to 0.96 and Reynolds numbers from 3.4×10^6 to 10×10^6 (fig. 6). At $M = 0.95$ the wing shock wave approaches the probe at $x/c = 0.218$. A wing pressure distribution was measured

with each boundary-layer survey. It was found that there was no probe-support interference with the wing surface pressures at the position of the probe tip. Reference 6 describes one problem with the wing pressures: a degree of pressure unsteadiness behind an unsteady shock wave, which is common for supercritical airfoils. Boundary-layer surveys were made in this region of pressure unsteadiness. Three surveys were made at each test condition, and it was found that pressure unsteadiness did not affect the mean pressures in the boundary layer as is often true of turbulent boundary-layer surveys. Due to mechanical difficulties with the laser drive mechanism, only limited three-component laser velocimeter measurements were obtained. However, two-component surveys were obtained at $M = 0.82$ at $x/c = 0.900$, 1.0(-) just upstream of the trailing edge, and 1.0(+) just downstream, to within 0.5 mm of the surface. These 2-D surveys are useful since the actual flow direction was measured to be less than 10°.

DATA REDUCTION

Static-pressure measurements were reduced to standard pressure coefficients using tunnel conditions measured at the beginning of each data set. Pressure coefficient data at each spanwise station were numerically integrated by Simpson's rule to determine section and overall normal-force and pitching-moment coefficients. Pitot-pressure measurements from the 3-hole flow-direction probe and the closest surface-static pressure were used to calculate the standard boundary-layer characteristics listed in the Nomenclature and tabulated on the microfiche. Calculated crossflow velocity components are defined in the flow-direction sketch in figure 7 and in the Nomenclature. The coordinate systems used in the data reduction are those commonly used in 3-D boundary-layer analysis. Computer plots of chordwise pressure distributions and boundary-layer surveys were generated and analyzed immediately after each test run.

Flow-direction angles and pitot-pressure corrections for flow angle were determined using the calibration functions recommended in reference 7 and shown in figure 8. The differential pressures between (1) the right and left tubes (a measure of flow angle), and (2) the actual and the indicated pitot pressures (a measure of the pitot-pressure correction) were normalized by the difference between the indicated pitot pressure p_C and the average of the right and left pressures, as follows:

$$PSI = f(Y4) \qquad Y4 = (p_R - p_L)/\{p_C - [(p_R + p_L)/2]\}$$

$$p_C = f(Y6) \qquad Y6 = (p_t - p_C)/\{p_C - [(p_R + p_L)/2]\}$$

These calibration factors were reported in reference 7 to be independent of Reynolds number (based on tube outside diameter) over a range of 1×10^3 to 4×10^4 and independent of Mach number up to the maximum measured of 0.9. Since local Mach numbers over Wing C were expected to be as high as 1.8, the 3-hole probe was calibrated at Mach numbers up to 2. At Mach numbers up to 0.9 the calibrations were independent

of test Mach and Reynolds numbers. At Mach numbers above 0.9, deviations occurred at flow angles greater than 15°. For example, the flow angle at 30° could be in error by as much as 5°.

In case the flow angles at the boundary-layer survey stations were found to be greater than 15° at local Mach numbers greater than 0.9, it would be necessary to make a Mach number correction to probe measurements; therefore, a method was sought that could be incorporated in the data reduction to determine a local Mach number. The method of determining local Mach number need only be approximate, since the Mach number corrections do not vary strongly with Mach number.

Three correlation factors that do vary with Mach number were found and investigated (fig. 8(d)), labeled Y10, Y11, and Y12; all three were obtained using combinations of the measured probe and surface static pressures.

$$Y10 = f[(p_R + p_L)/2p_C]$$

$$Y11 = f(p/p_C)$$

$$Y12 = f\ 2p/(p_R + p_L)$$

The correlation factor Y10 is based on the probe measurements alone, which is formulated by the ratio of the average of the right and left pressures to the center pressure. Y10 is the least sensitive to Mach number, but it might be usable since it is not sensitive to flow direction angle up to 30°. Both Y11 and Y12 use a combination of measured surface-static and probe pressures. The relation Y11 is the ratio of the surface-static and center pressures, so that at zero flow-direction angle it is identical to the ratio of free-stream static to pitot pressures. Y11 is most sensitive to Mach number; its estimated probable error is composed of only two random pressures; however, it varies with flow-direction angle. Its estimated probable error is the most favorable of the three relations because it is composed of only two random pressures. The relation Y12 is the ratio of the measured surface static pressure to the average of the right and left probe pressures. This relation is similar to the ratio of static to dynamic pressures, it is sensitive to Mach number, it does not vary with flow-direction angle up to 30°; however, its estimated probable error is composed of three random pressures, rather than two.

Since the flow-direction angles from this test were found to be generally less than 10°, and since Mach number effects occurred only at flow angles greater than 15°, no corrections were necessary for Mach number effects.

RESULTS

The boundary-layer data and plots of these data are tabulated on the enclosed microfiche records (which will be found on the book cover) for the test conditions listed in table 2. A sample data tabulation is given in table 3. Each survey is

identified by run and sequence numbers. All symbols are defined in the Nomenclature section. Samples of the boundary-layer-survey plots are given in figures 9 and 10 for $x/c = 0.218$ and 0.421 from runs:sequences of 224:1 and 214:1, respectively, at $M = 0.82$ and $Re = 10 \times 10^6$.

The measured 3-D laser velocity profiles (not tabulated on microfiche) are presented in figure 11 for $M = 0.70$ and 0.82. The measured turbulent-fluctuation velocities at $M = 0.70$ were used to obtain the distributions of chordwise and vertical Reynolds stresses (fig. 12). Figure 13 shows the measured flow angles through the boundary layer at $M = 0.70$ from the limited 3-D laser measurements. Although the accuracy of the 3-D measurements was not as good as desired, the measurements appear to show agreement with the oil-flow angles at the surface of about 8° outboard, and with the inviscid flow calculations of about 5° inboard at the edge of the boundary layer (refs. 5 and 6).

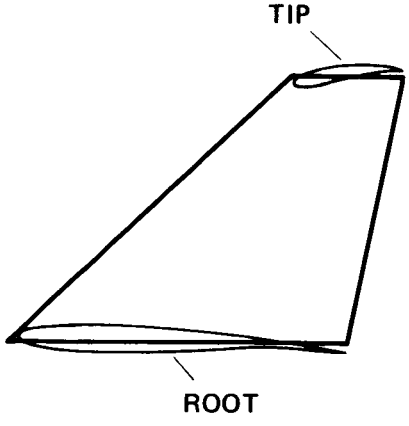
WING –	A	B	C
ASPECT RATIO –	8.0	3.8	2.6
L.E. SWEEP –	27°	35°	45°
TAPER RATIO –	0.4	0.4	0.3

Figure 1.- Sketch of small-scale wing models for Lockheed-Georgia tests in their high Reynolds number facility.



AR = 2.6 $\quad \lambda = 0.3$

$\Lambda_{L.E.} = 45°$ $\quad \Lambda_{T.E.} = 9.7°$

$S/2 = 0.625\ m^2$ $\quad b/2 = 0.902\ m$

$t_{ROOT}/C_R = 0.06$ $\quad t_{TIP}/C_T = 0.10$

$C_{ROOT} = 1.066\ m$ $\quad C_{TIP} = 0.318\ m$

M.A.C. = 0.760 m

$\alpha_{O,R} = 2.38°$ $\quad \alpha_{O,T} = -5.79°$

Figure 2.- Wing C geometry.

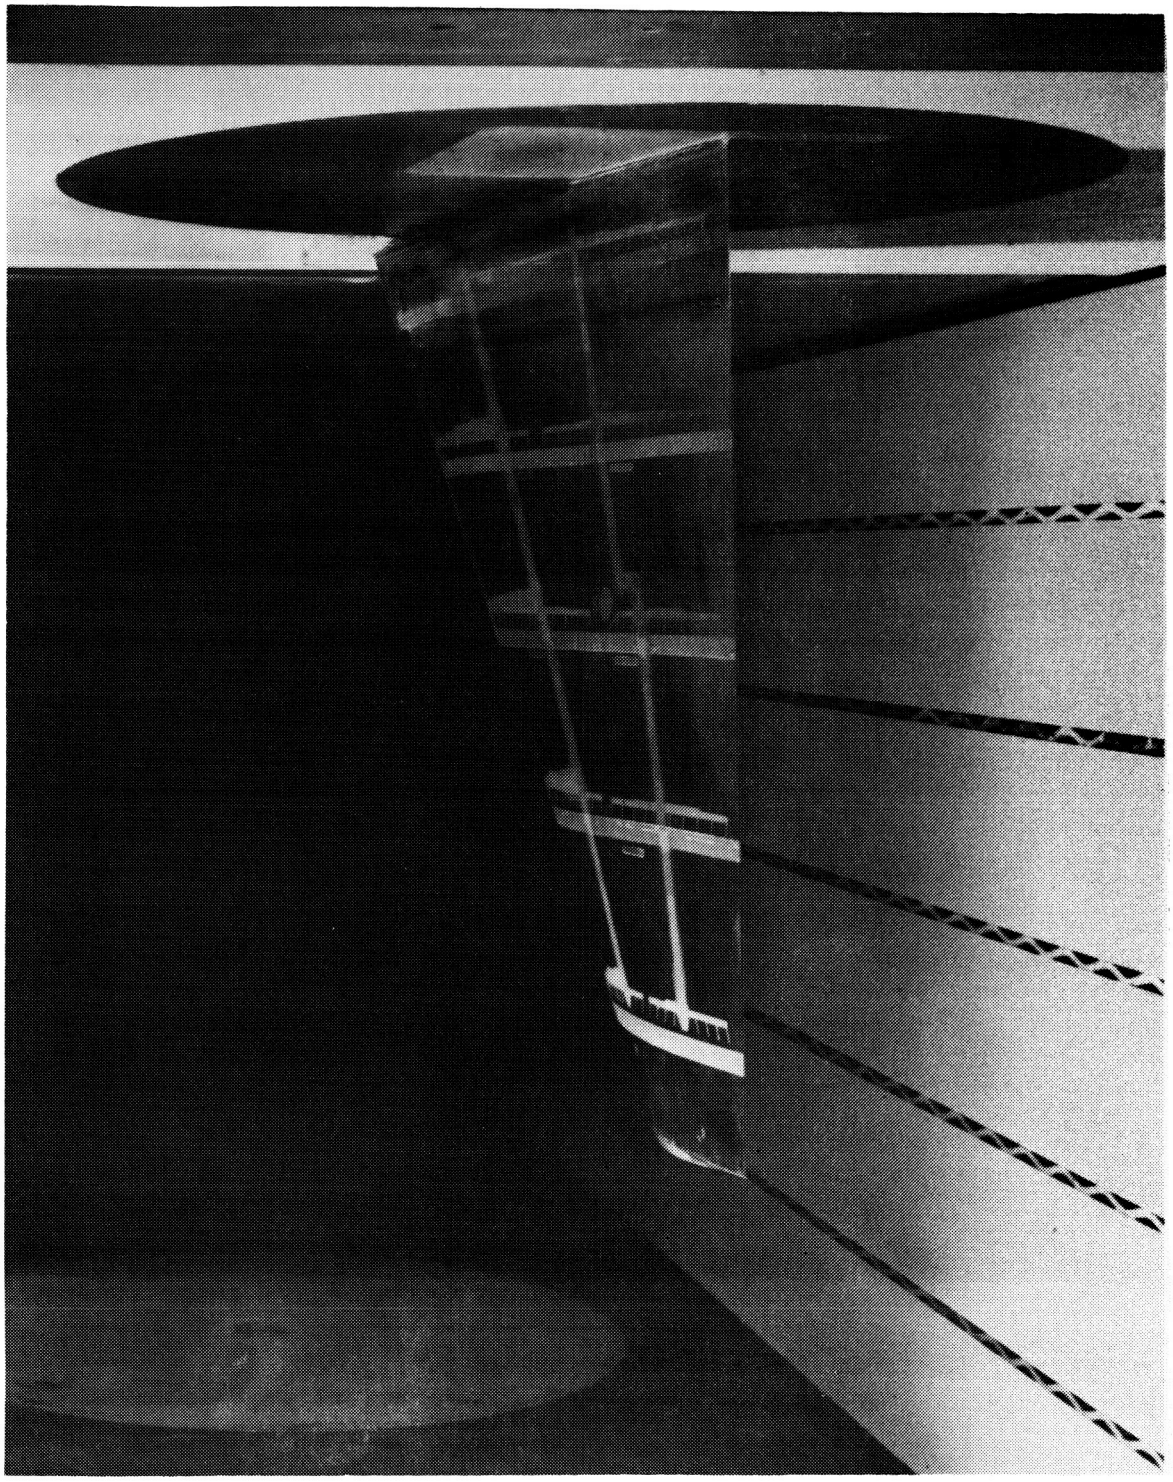


Figure 3.- Rear view of 0.9 m semispan model of Wing C mounted on the wall of Ames 6- by 6-Foot Transonic Wind Tunnel.

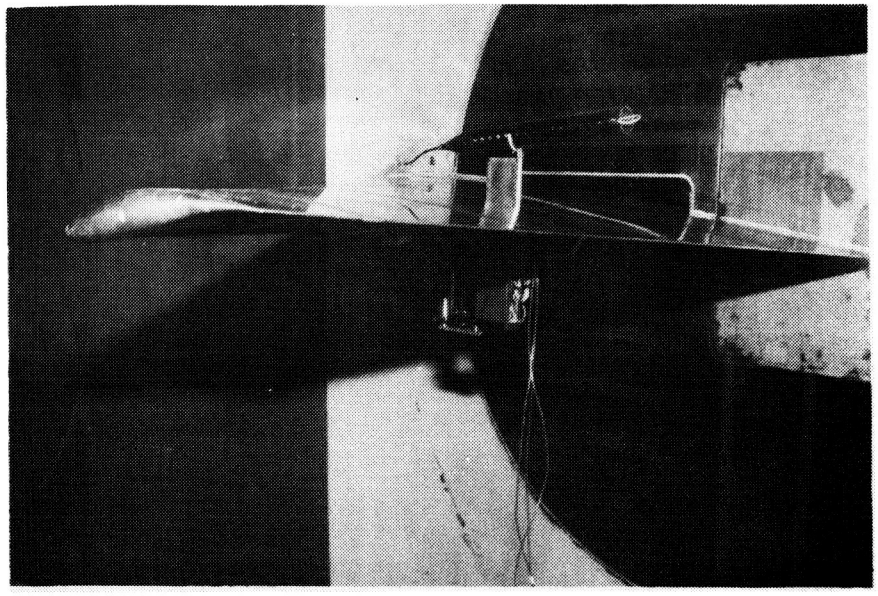

Figure 4.- Boundary-layer-probe traversing mechanism.

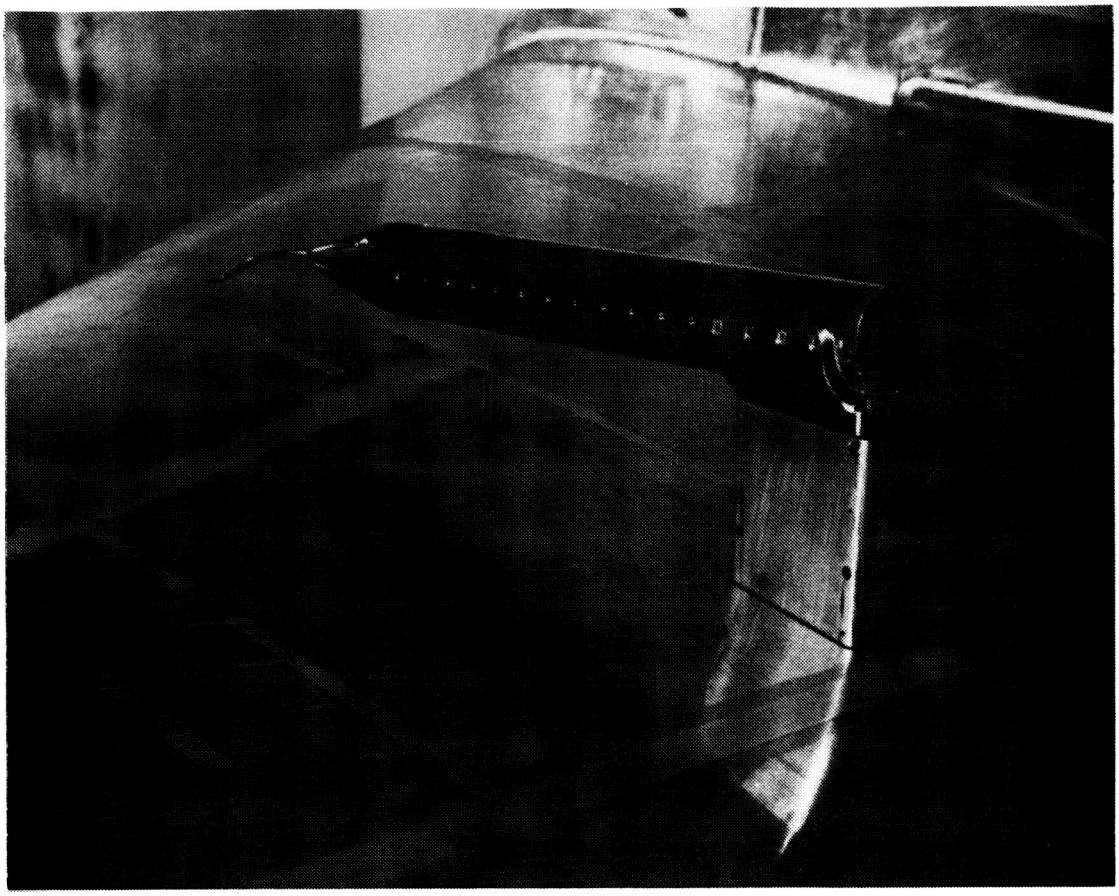
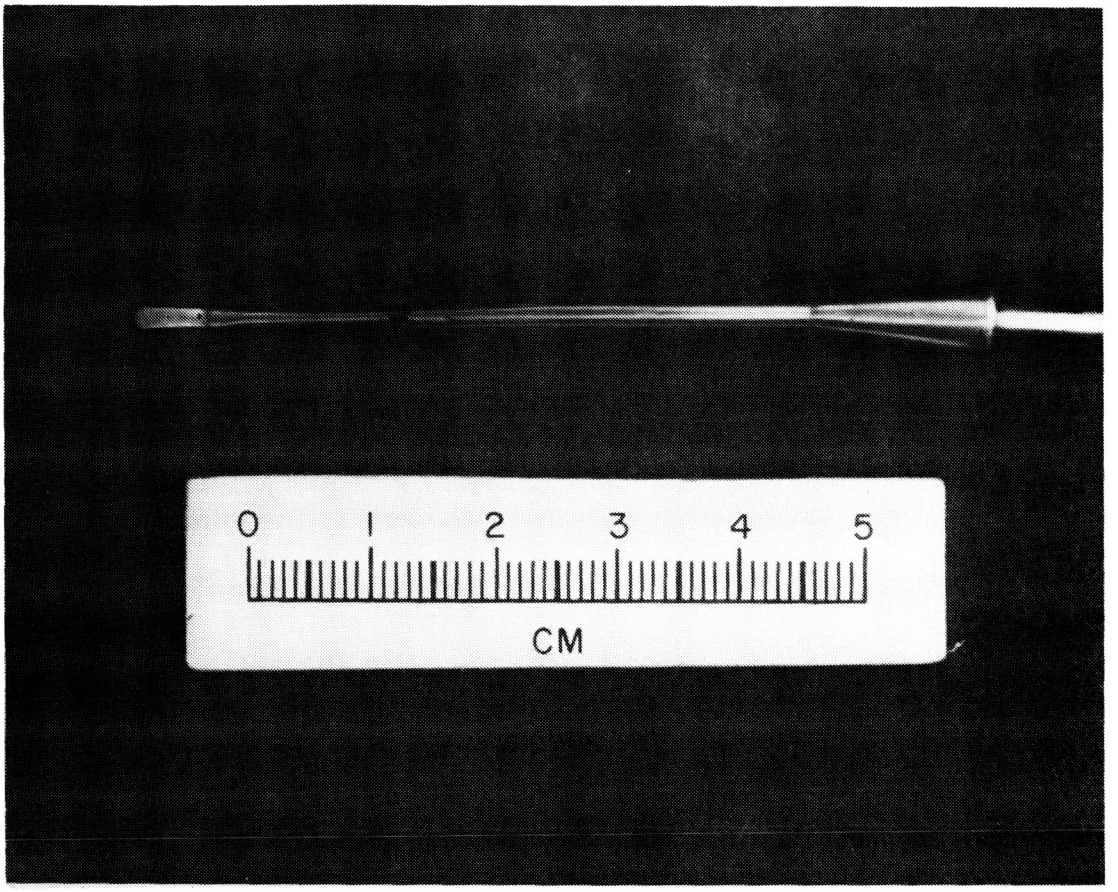


(a) Probe and vertically-traversing probe support.

Figure 5.- Boundary-layer flow-direction probe.



(b) Top view of 3-hole flat tip probe.

Figure 5.- Concluded.

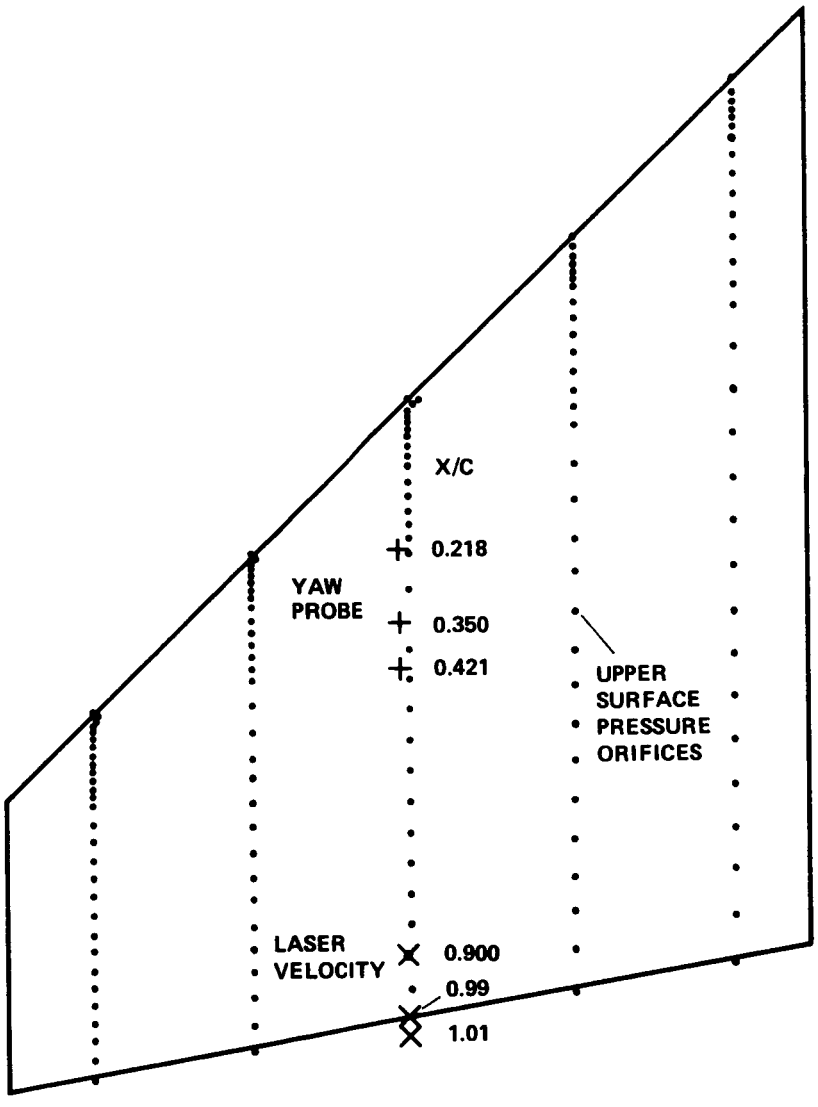


Figure 6.- Location of boundary-layer surveys; $\alpha = 5°$.

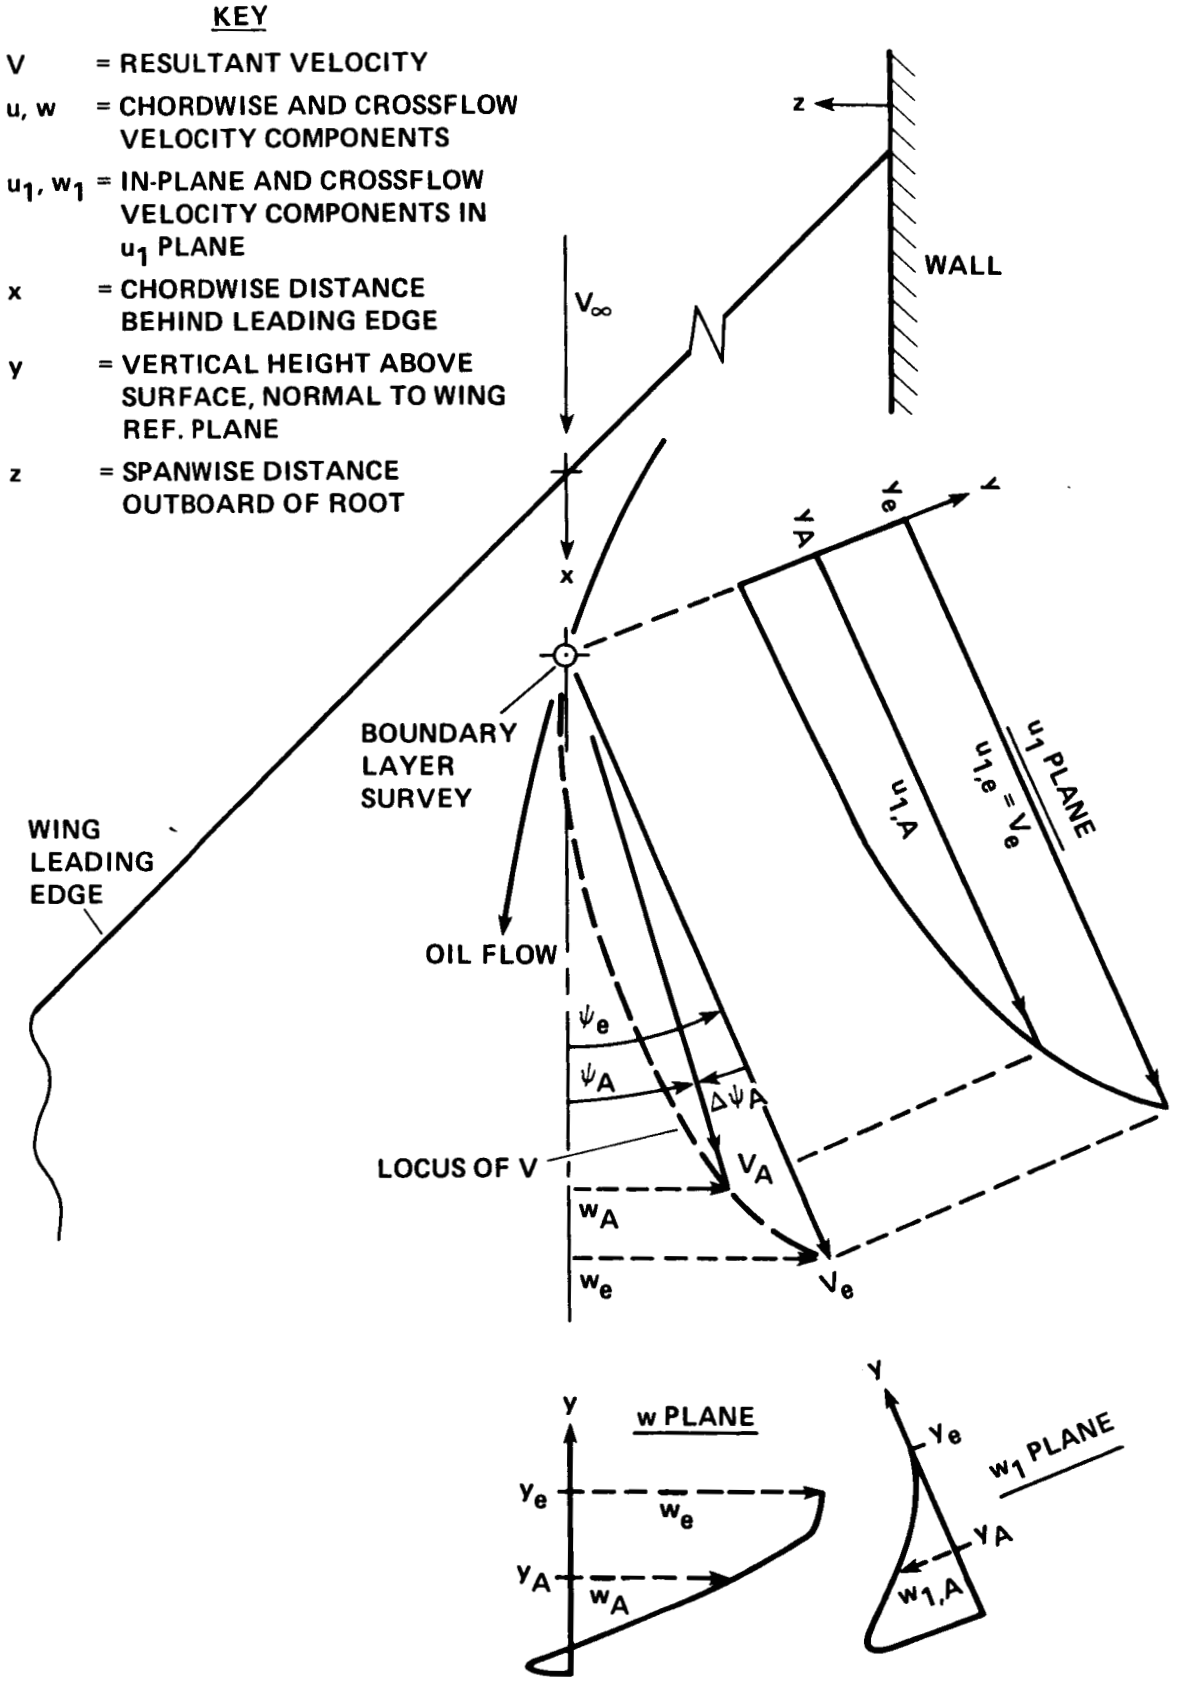

Figure 7.- Nomenclature for boundary-layer velocities and flow directions (see sample profiles, figs. 9 and 10).

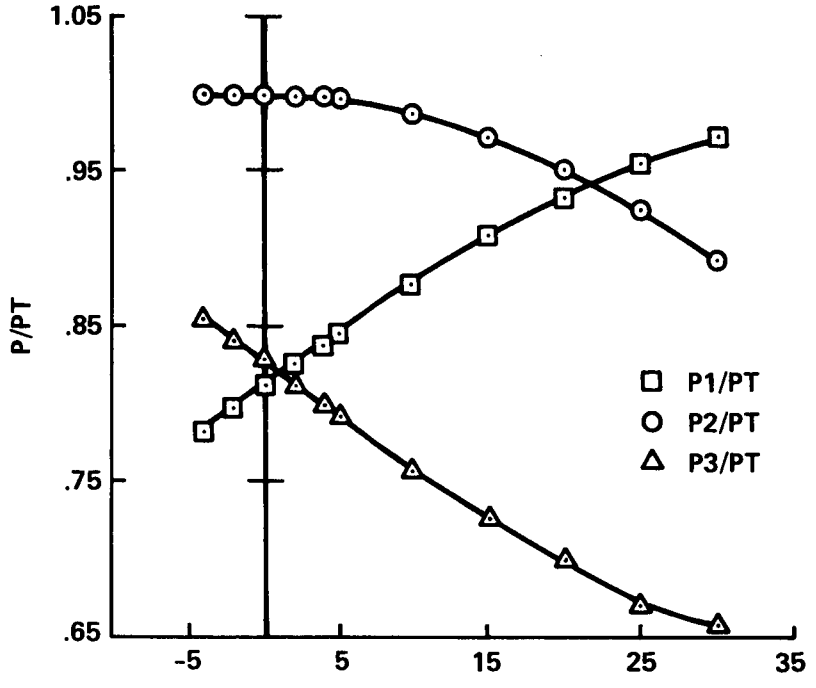
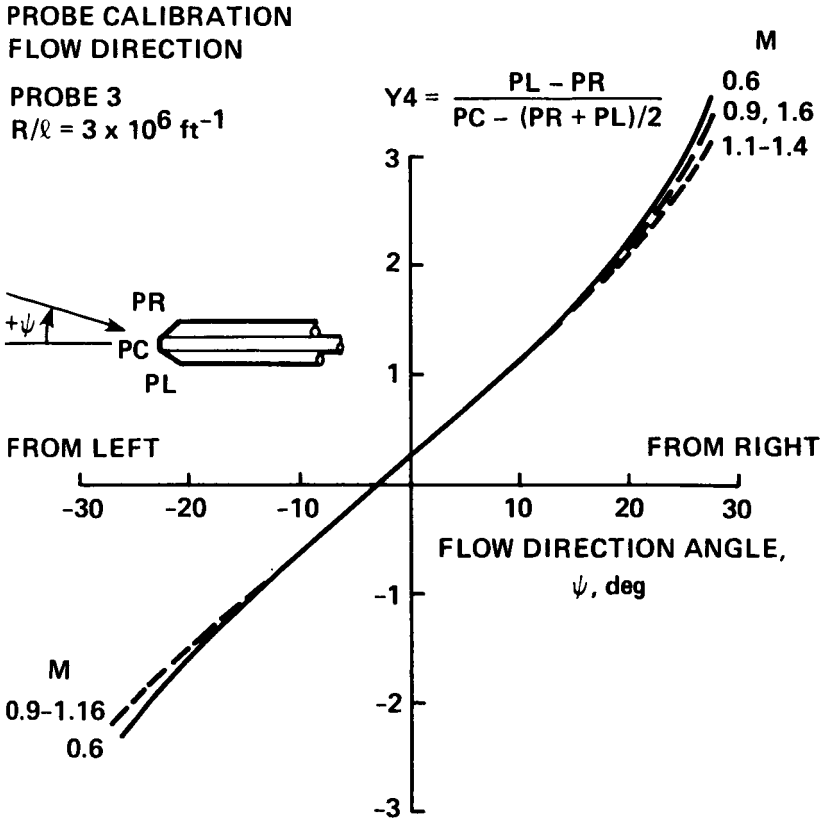


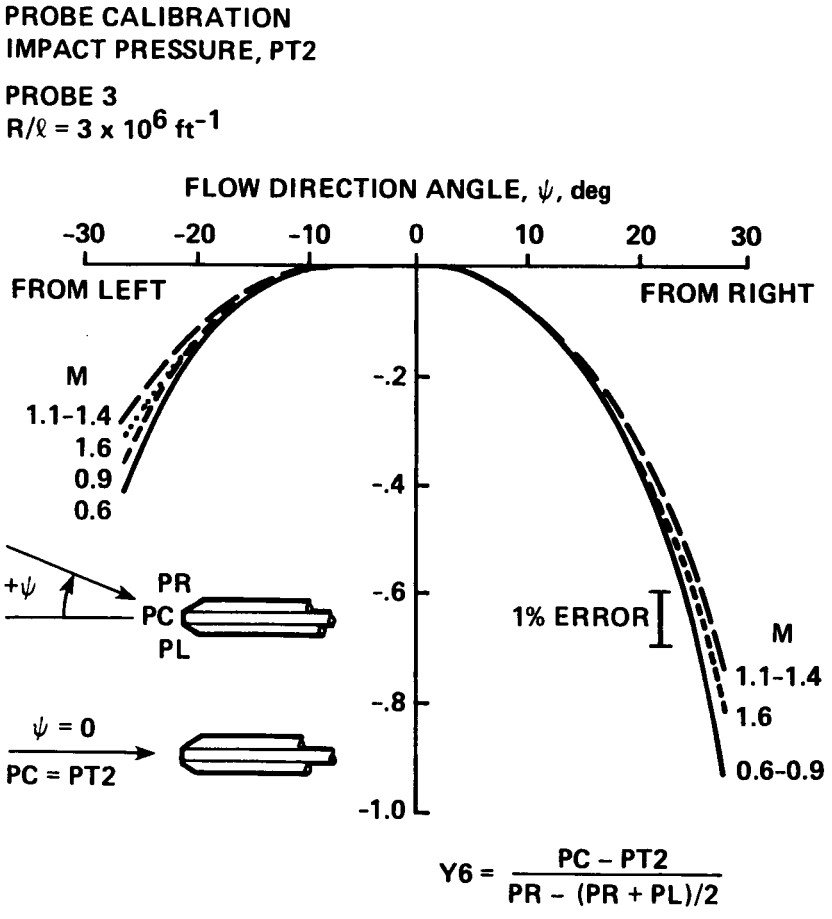
(a) Probe pressures vs flow-direction angle.

Figure 8.- Calibration curves for 3-hole flow-direction probe.



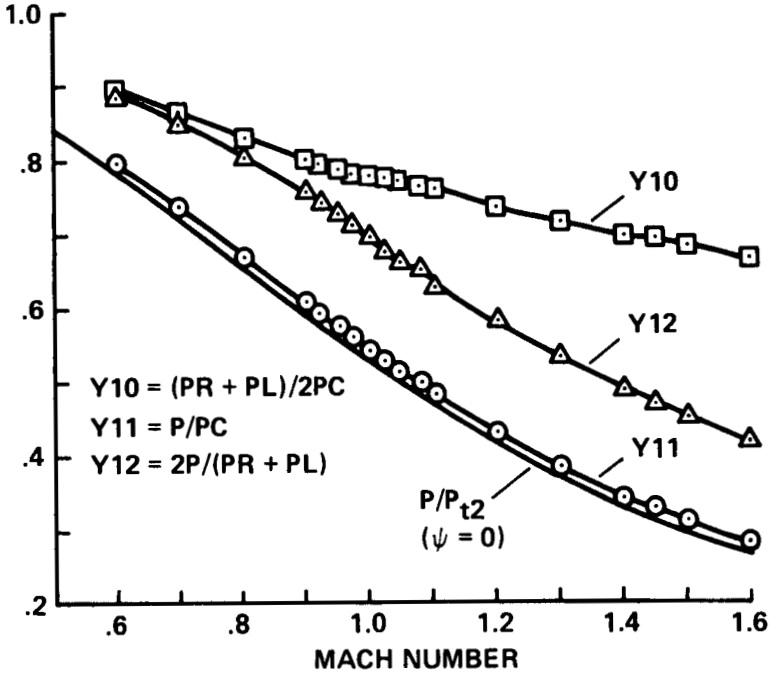
(b) Probe differential-pressure factor (Y4) vs flow-direction angle.

Figure 8.- Continued.



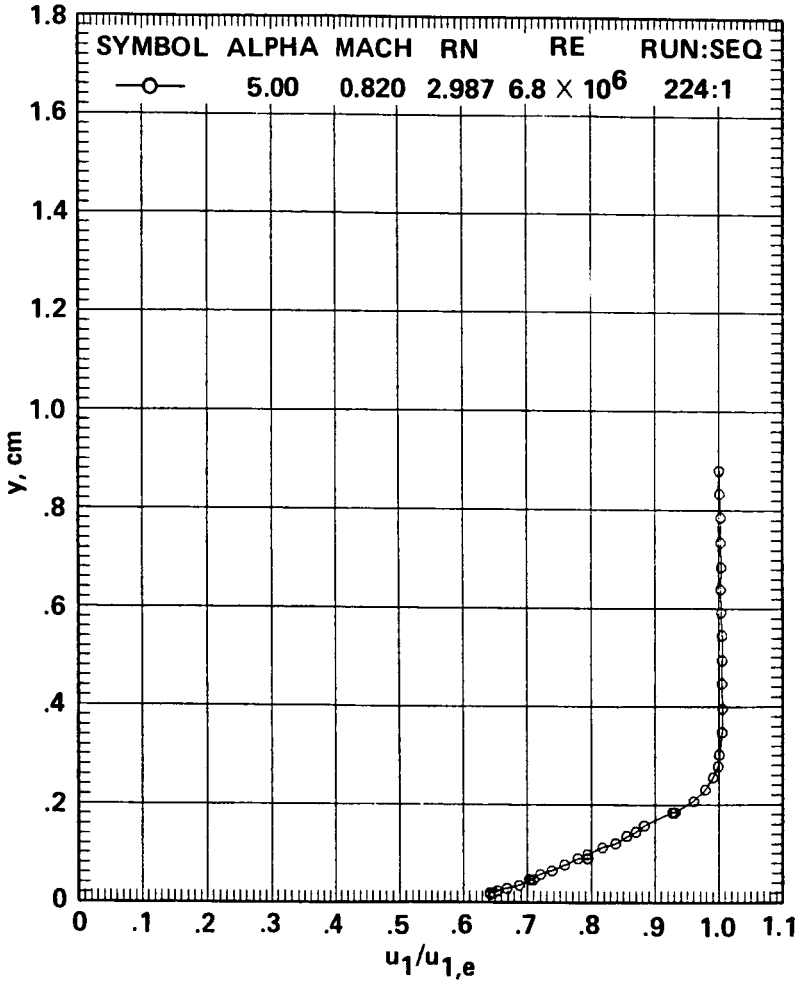
(c) Probe pitot-pressure factor (Y6) vs flow-direction angle.

Figure 8.- Continued.



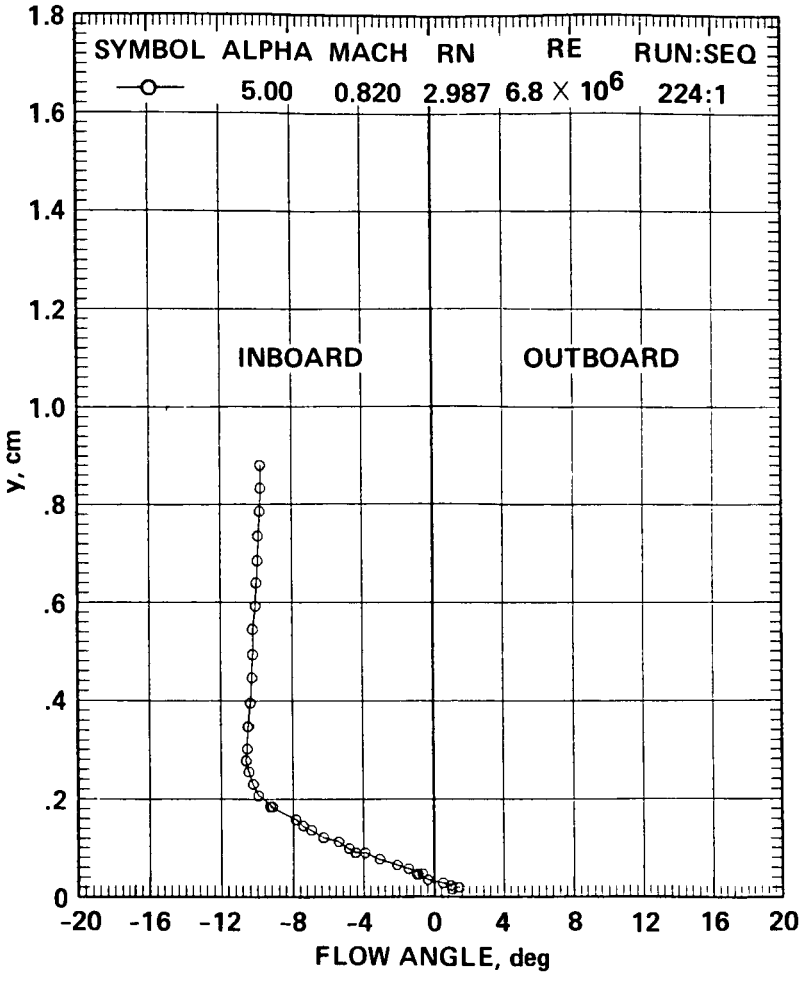
(d) Probe Mach number sensitivity at $\psi = 20°$.

Figure 8.- Continued.



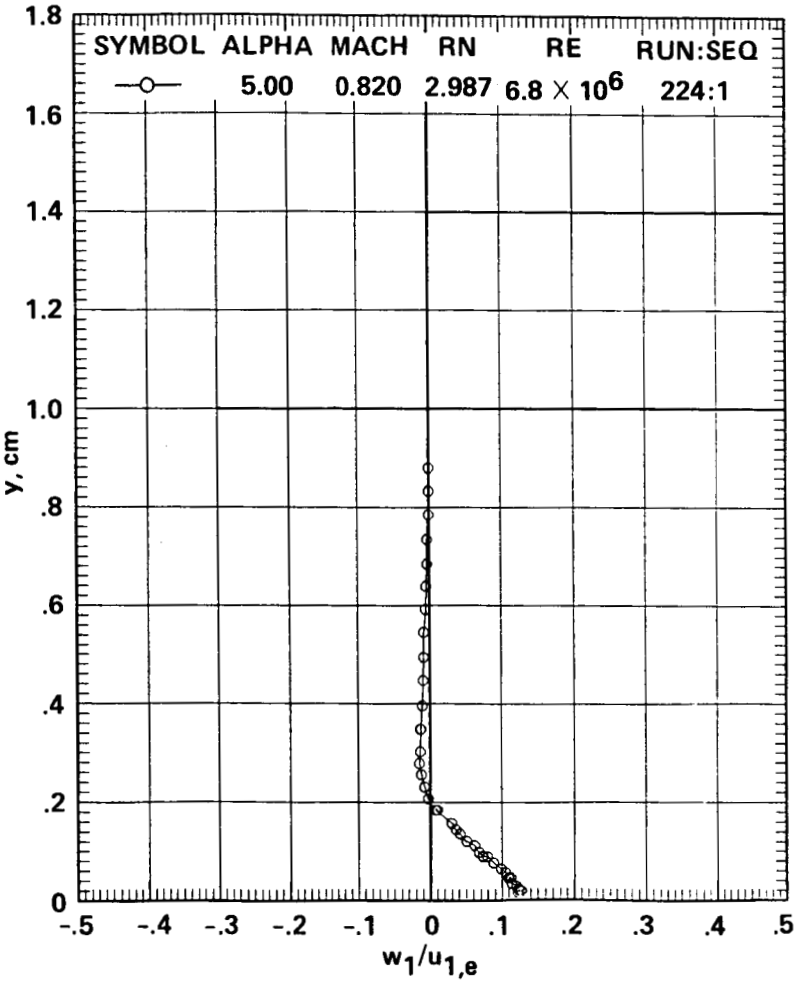
(a) Velocity profile.

Figure 9.- Sample plots of turbulent mean-velocity and flow-direction profiles from boundary-layer survey with 3-hole probe; M = 0.82, α = 5°, Re = 6.8×10^6, x/c = 0.218.



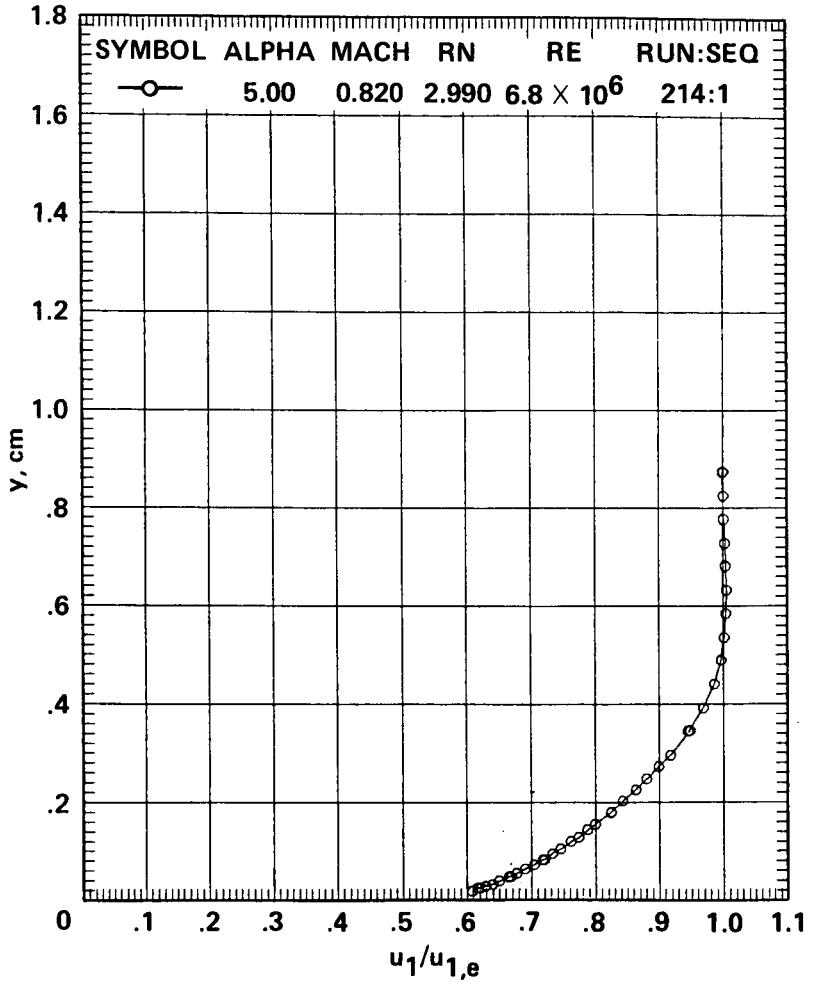
(b) Flow direction angle.

Figure 9.- Continued.



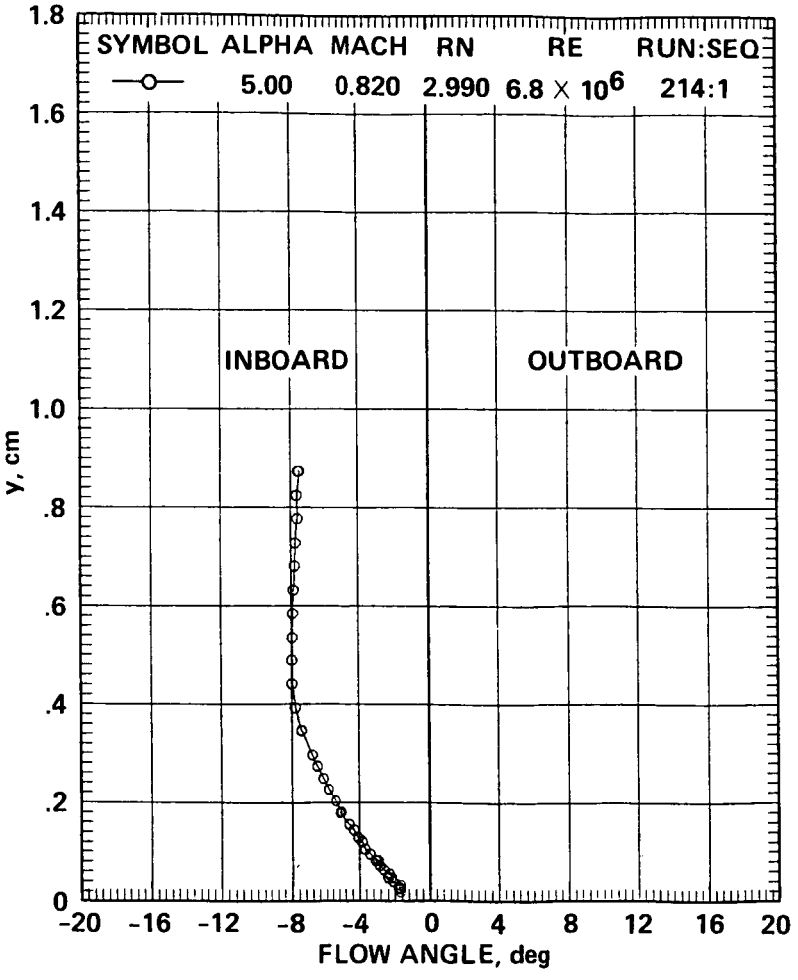
(c) Crossflow velocity component.

Figure 9.- Concluded.



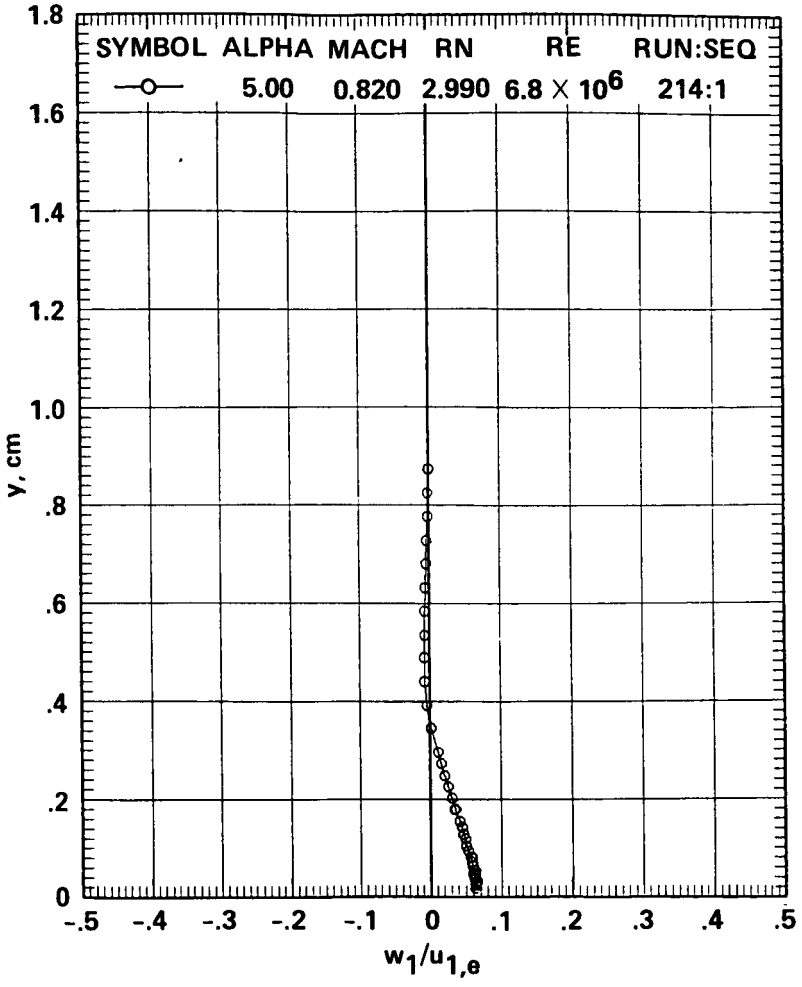
(a) Velocity profile.

Figure 10.- Sample plots of turbulent mean-velocity and flow-direction profiles from boundary-layer survey with 3-hole probe; M = 0.82, α = 5°, Re = 6.8×10^6, x/c = 0.421.



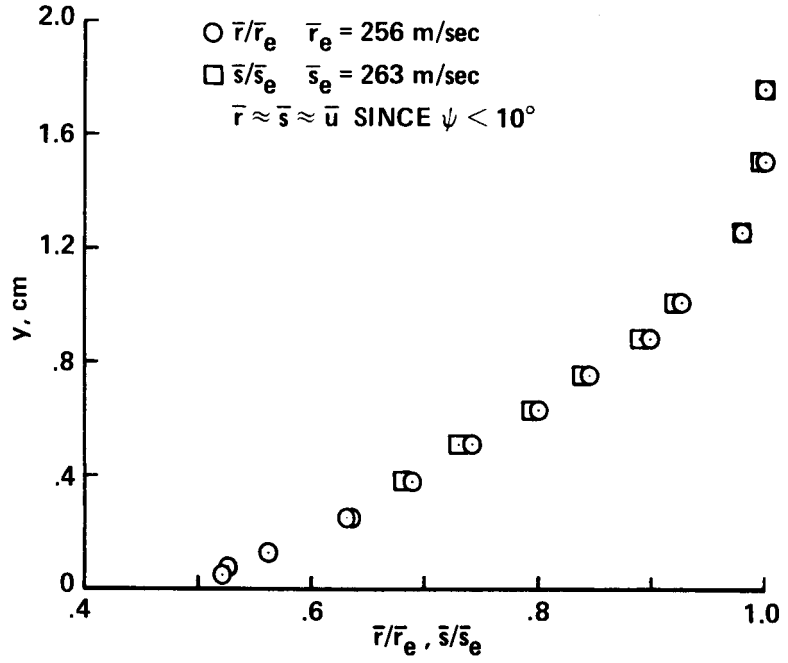
(b) Flow direction angle.

Figure 10.- Continued.



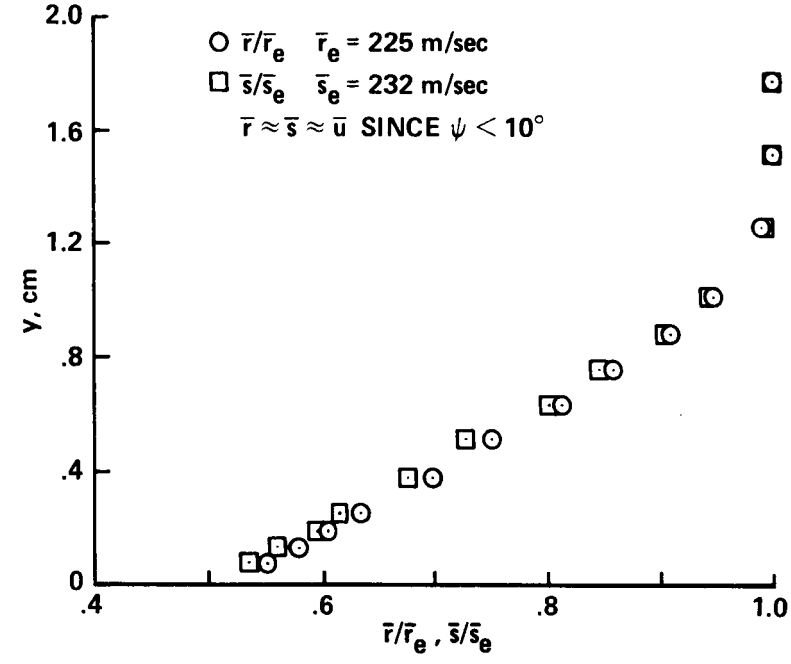
(c) Crossflow velocity component.

Figure 10.- Concluded.



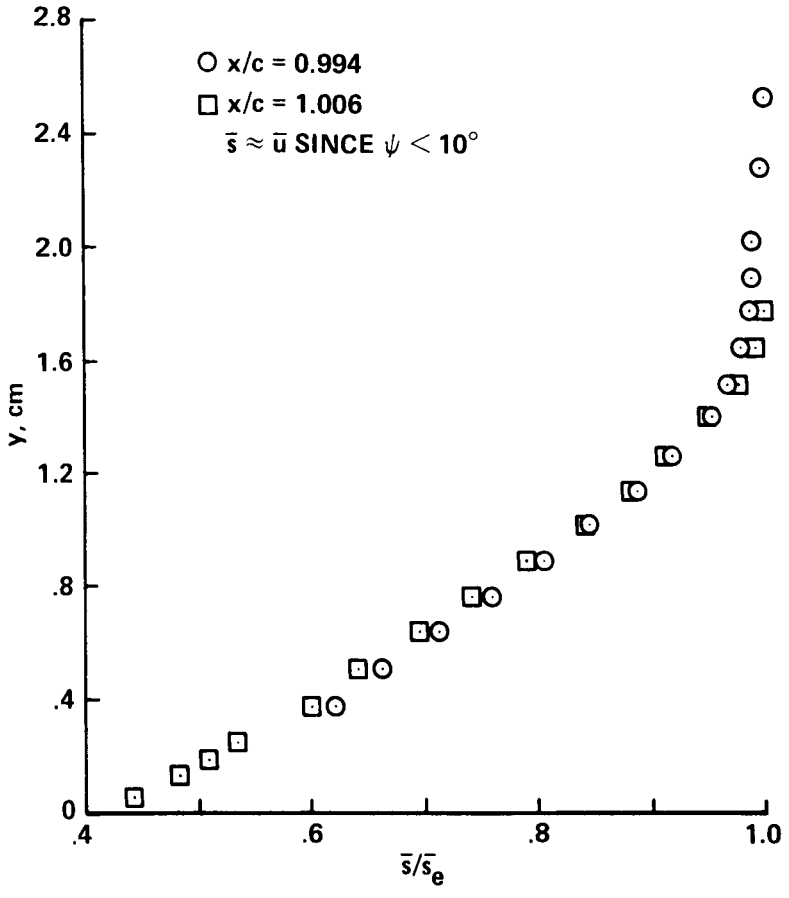
(a) M = 0.82, x/c = 0.90.

Figure 11.- Turbulent boundary-layer velocity surveys from laser velocimeter; α = 5°, Re = 6.8×10^6.



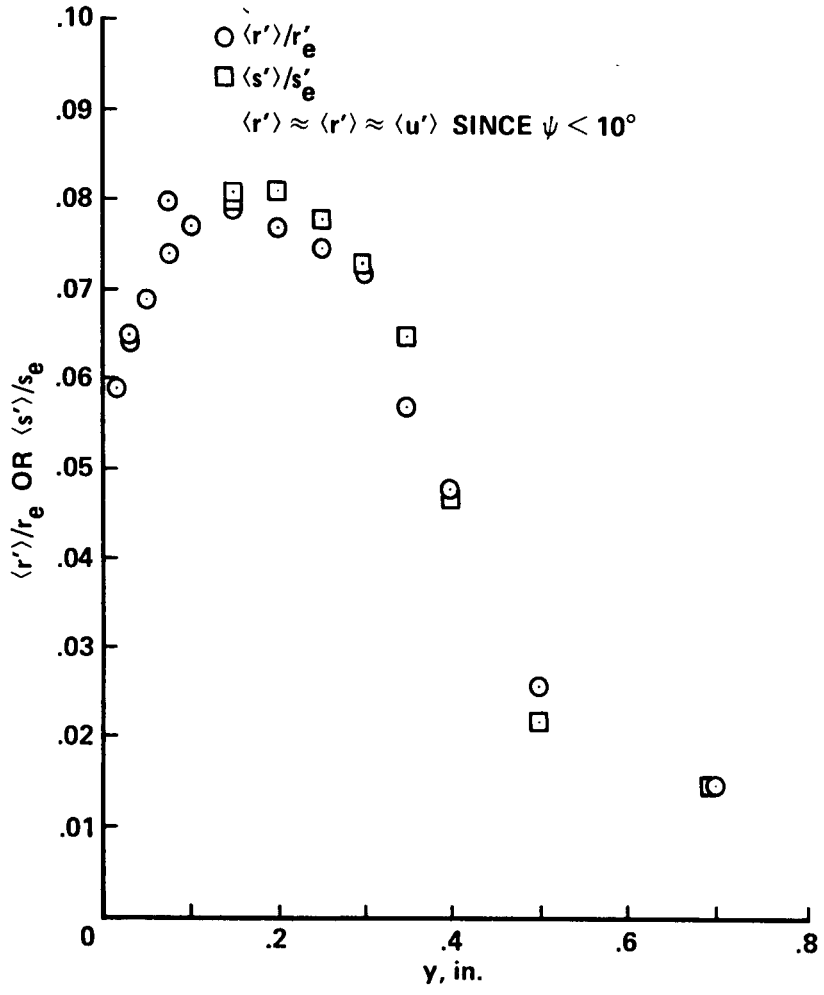
(b) M = 0.82, x/c = 1.0.

Figure 11.- Continued.



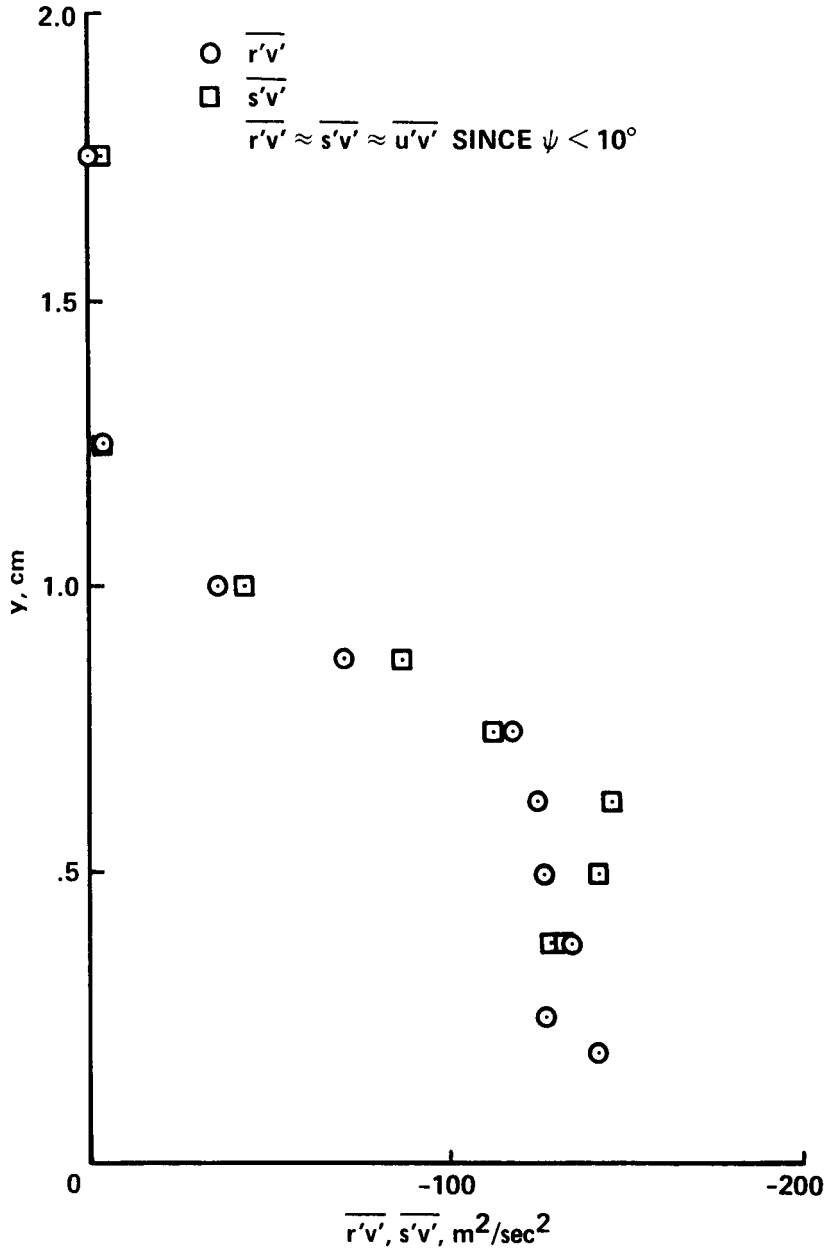
(c) M = 0.70, x/c = 0.90.

Figure 11.- Concluded.



(a) $\langle r' \rangle / r_e$ and $\langle s' \rangle / s_e$.

Figure 12.- Turbulent boundary-layer velocity-fluctuation surveys from laser velocimeter; M = 0.70, α = 5°, Re = 6.8×10^6, x/c = 0.90.



(b) $\overline{r'v'}$ and $\overline{s'v'}$.

Figure 12.- Concluded.

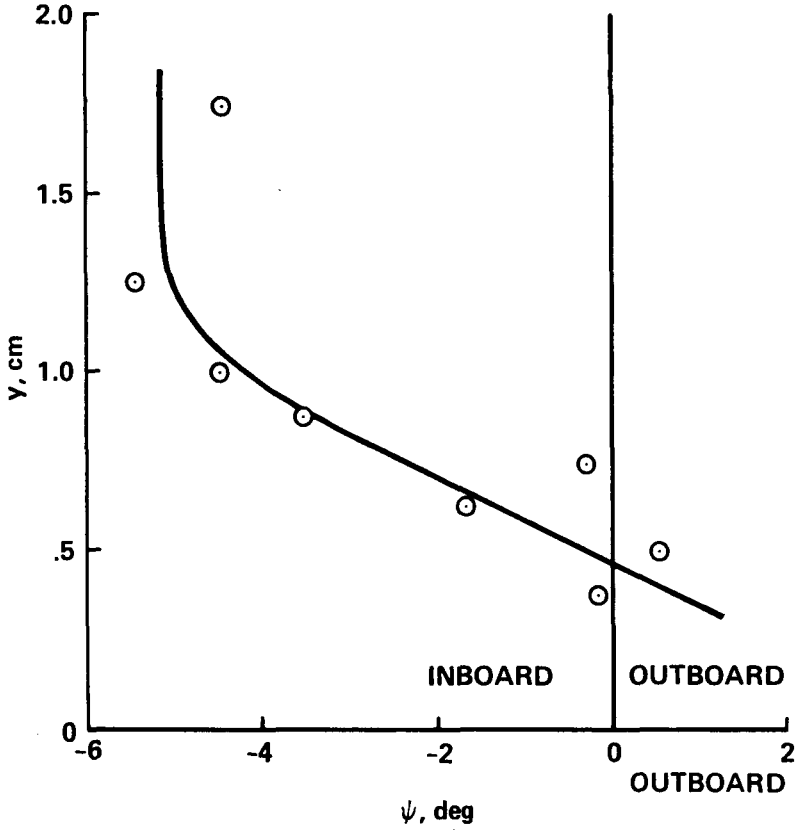


Figure 13.- Boundary-layer flow-direction angles from 3-D laser velocimeter; $M = 0.7$, $\alpha = 5°$, $Re = 6.8 \times 10^6$, $x/c = 0.90$.

16. Abstract

Tabulations and plots are presented of boundary-layer velocity and flow-direction surveys from wind-tunnel tests of a large-scale (0.90 m semi-span) model of the NASA/Lockheed Wing C. This wing is a generic, transonic, supercritical, highly three-dimensional, low-aspect-ratio configuration designed with the use of a three-dimensional, transonic full-potential-flow wing code (FLO22). Tests were conducted at the design angle of attack of 5° over a Mach number range from 0.25 to 0.96 and a Reynolds number range of 3.4×10^6 to 10×10^6. Wing pressures were measured at five span stations, and boundary-layer surveys were measured at the midspan station. The data are presented without analysis.
