

NASA CASE NO. LEW-14734-1PRINT FIG. 2NOTICE

The invention disclosed in this document resulted from research in aeronautical and space activities performed under programs of the National Aeronautics and Space Administration. The invention is owned by NASA and is, therefore, available for licensing in accordance with the NASA Patent Licensing Regulation (14 Code of Federal Regulations 1245.2).

To encourage commercial utilization of NASA-owned inventions, it is NASA policy to grant licenses to commercial concerns. Although NASA encourages nonexclusive licensing to promote competition and achieve the widest possible utilization, NASA will consider the granting of a limited exclusive license, pursuant to the NASA Patent Licensing Regulations, when such a license will provide the necessary incentive to the licensee to achieve early practical application of the invention.

Address inquiries and all applications for license for this invention to NASA Patent Counsel, Lewis Research Center, Mail Code 301-6, 21000 Brookpark Rd., Cleveland, OH 44135.

Approved NASA forms for application for nonexclusive or exclusive license are available from the above address.

FIG. 4

AWARDS ABSTRACT

A graphite fiber reinforced polymer matrix is layed up, cured, and thermally aged at about 750°F in the presence of an inert gas. The heat treatment improves the structural integrity and alters the electrical conductivity of the materials. In the preferred embodiment PMR-15 polyimides and Celion-6000 graphite fibers are used.

INVENTOR(S): Kenneth J. Bowles
Carl E. Lowell

EMPLOYER: NASA Lewis Research Center

EVALUATOR: Salvatore J. Grisaffe

SERIAL NO.: 279,624

FILING DATE: December 5, 1988

Light Weight Polymer
Matrix Composite Material

Origin of the Invention

The invention described herein was made by employees of the United States Government and may be manufactured and used by or for the Government for governmental purposes without the payment of any royalties thereon or therefor.

Technical Field

This invention is concerned with improving the structural integrity of fiber reinforced composites that are made with thermally treated polymers as their matrices and are exposed to air at high temperatures. The invention is further concerned with the production of components that can be used at temperatures well above those that can be tolerated by current state-of-the-art polymer matrix materials.

The projected material needs for aircraft propulsion systems for the near future are processable low density polymer matrix composites which are thermo-oxidatively and structurally stable at a temperature of 700°C and possibly 800°C. Conventional polymer matrix composite materials cannot meet these requirements.

A state-of-the-art high temperature polymer matrix for use in advanced composites is a polyimide described in U.S. patent No. 3,745,149 and known commercially as PMR-15. When this polyimide is used with high modulus graphite fibers, the resulting composites can be used for long periods of time at 550°F and for shorter periods of time at 600°F. At this higher temperature the interlaminar shear strength is about 50% of the value at room temperature. At higher temperatures the value decreases even more.

As with other polymer matrix composites the use-temperature limit, as determined by structural integrity, for PMR-15 is limited by the T_G of the resin. The T_G designates the temperature at which the matrix changes from an elastic material (below T_G) to a rubbery material (above T_G). As a rubbery material with an extremely low

modulus, the matrix can no longer transfer loads from fiber to fiber, and the composite stiffness or structural integrity is lost. The T_G of PMR-15 is one of the highest of the state-of-the-art engineering polymers and is normally about 635°F. Inasmuch as the transition at the T_G is not sharp, but occurs over a finite temperature range, even short excursions near 635°F can result in the loss of structural integrity for PMR-15 matrix composites.

Most composite materials are literally composed of fibers that are cemented together with an organic polymer matrix. Therefore, the electrical resistivity across the composite, perpendicular to the plane in which the fibers lie, is very much dependent on the resistivity of the matrix material. As an example, Celion 6000/PMR-15 composites have a resistivity of 25.4 ohm-cm across the fibers and 0.0346 ohm-cm parallel to the plane of the fibers. The highly conductive Celion 6000 graphite fibers dominate in producing a low resistivity in the direction parallel to the fiber axes. Most organic fibers have high resistivities and therefore the resistivity through the thickness of a composite plate is also high.

Often the structure materials that are used in aircraft components must have low electrical resistivities to dissipate lightning strike voltages, to provide a path for grounding electrical and electronic circuits, and possibly for providing a medium for resistance heating anti-icing and deicing techniques. The low electrical resistivity suggests that such new materials may also possess high thermal conductivity characteristics. This would enable state-of-the-art anti-icing and deicing techniques to be used with these composite materials that are required for the aircraft of the future.

It is, therefore, an object of the present invention to provide a method for using thermal processing of polymer matrix materials to bring about changes in their properties.

Another object of the invention is to utilize thermal processing technology to significantly improve the structural

integrity of fiber reinforced composites that are made with thermally treated polymers as their matrices are exposed to very high temperatures.

A further object of the invention is to change the chemical structure of polymer matrix materials to increase the T_G above the desired use temperature.

A still further object of the invention is to remove those volatiles that are always produced during the pyrolysis of organic matrices at a rate slow enough that blistering will not occur within the composite.

Still another object of the invention is to decrease the electrical resistivity and possibly raise the thermal conductivity of the polymeric material by converting this material to a more electrical conducting, possibly semi-carbonaceous material.

Background Art

U.S. patent No. 4,016,140 describes a heat treatment in a temperature range between 300°F and 700°F prior to molding. This treatment provides a molecular weight increase necessary for good copolymer properties and more complete imidization of the polymers. In addition, this treatment prevents the formation of water vapor which would cause void formation later in the molding step.

U.S. patent No. 4,167,620 to Chen describes the heat treating of polyimide resins to improve their physical properties. The process is used to remove volatiles generated and contained within the polyamide-amides and polyamic acids that will cause voids, delaminations and warping of a structure made from this material when heated to near the heat deflection temperature. A circulating gas is used to help flush the volatiles from the solid. The treatment is likewise a post cure which promotes oxygen enhanced crosslinkings within the polymer to increase the heat deflection temperature about 30°F.

Yoshimura et al patent Nos. 4,401,590 and 4,497,728 are both concerned with processes which alter the conductivity of polyimides.

This is accomplished by heating the material to a temperature between 400°C and 1,000°C.

Pater patent No. 4,560,742 describes the standard post cure for a polyimide PMR-15 matrix composite. The heating does not take place in an inert atmosphere and the composite material is heated to a temperature as high as 600°F.

Edelman patent No. 4,395,514 is directed to graphite reinforced polyimide resin materials having improved structural properties. After lay-up, the composite material is heated to temperatures as high as 635°F for comparatively short periods of time and not in an inert atmosphere. The main objective is to reduce curing temperature from 600°F to a temperature of about 350°F to 450°F.

Disclosure of the Invention

The present invention relates to graphite fiber reinforced polyimide resin materials for structural use above 550°F. The materials are heat treated at about 750°F in the presence of an inert gas. This heat treatment improves the structural integrity and alters the electrical conductivity of the materials.

The processing is done on a fabricated structure after the lay-up and curing has been completed. This material can be used for short times at temperature well above the current limit of 550°F at which existing high temperature polyimide matrix material can operate for extended periods.

Unlike present day polymer matrix composites, the materials produced by the thermal processing of the present invention will not experience large reductions in mechanical properties, such as stiffness and strength, as temperature increases past 600°F and even past 700°F. The materials can be used at temperatures well beyond current limits while retaining low temperature structural integrity.

In addition to the superior high temperature performance exhibited by the materials produced by the present process, the processing procedure also alters the electrical resistivity of the precursor composite matrix material. The thermal processing

decreases the electrical resistance significantly which increases the value of the material, particularly in the aerospace industry. Such a processing produces certain metal-like properties in polymer based materials.

Brief Description of the Drawings

The objects, advantages and novel features of the invention will be more fully understood from the following detailed description when read in connection with the accompanying drawings wherein

FIG. 1 is a graph showing nitrogen and air aging of Celion 6000/PMR-15 composites;

FIG. 2 is a bar chart illustrating the improvement in high temperature flexural properties achieved with thermal treatment of Celion 6000/PMR-15 composites;

FIG. 3 is a bar chart illustrating the increase in glass transition temperature obtained with nitrogen treatment; and

FIG. 4 is a bar chart illustrating the composite resistivity changes during isothermal aging in nitrogen at 700°F.

Best Mode for Carrying Out the Invention

Changes in chemical structure are obtained by the controlled thermal degradation of a polymer which produces improvements in high temperature mechanical properties and electrical properties over those of the starting material. Heat transfer properties also may be improved.

This controlled thermal degradation can be easily incorporated without the necessity for the development of new processing technology. Controlled thermal degradation is really a chemical structure change and can be compared to the metallurgical transformations caused by annealing and other types of heat treatments.

The process itself entails the thermal aging of a fully-cured graphite fiber reinforced polymer matrix composite in an inert gas, such as nitrogen or argon, or in a vacuum. The aging must take place at a temperature above the projected use temperature of the

proposed structure. The length of the thermal treatment must be enough to insure that further treatment will not result in further weight loss as illustrated in FIG. 1 which shows nitrogen and air aging. A particular weight loss value is characteristic for a particular material at a particular temperature.

Referring again to FIG. 1, the aging of a Celion 6000/PMR-15 composite in 371°C in air is shown by the line 10, while the aging of this composite in nitrogen at this temperature is shown by the line 12. Agings of this composite in nitrogen at 343°C and 427°C are shown by the lines 14 and 16 respectively.

The beneficial technical effects of the process is illustrated by the results of testing Celion 6000/PMR-15 unidirectional composites. Interlaminar shear strengths of treated and untreated composites are listed in Table I. Flexural strengths and moduli of treated and untreated Celion 6000/PMR-15 unidirectional composites are shown in FIG. 2.

TABLE I

	Interlaminar Shear Strength (Ksi)
Post cured and no aging.	17.2
Post cured and aged in N ₂ at 700°F for 335 hrs. room temp test.	16.9
Post cured and aged in N ₂ at 700°F for 335 hrs. and at 800°F for 230 hrs. room temp test.	8.8
Post cured and no aging. Tested at 700°F.	4.0
Post cured and aged 335 hrs. at 700°F 700°F test.	11.1
Post cured and aged 335 hrs. at 700°F and 800°F for 230 hrs. 700°F test.	7.7

Flexural properties of the composites are listed in Table II.

TABLE II

	Flex Strength (Ksi)	Flex Mod. (Msi)
Post cured and unaged. Tested at room temp.	205.8	21.5
Post cured and aged 335 hrs. at 700°F. Tested at room temp.	171.8	21.5
Post cured and unaged. Tested at 700°F.	70.2	12.2
Post cured and aged 335 hrs. at at 700°F. Tested at 700°F.	169.0	21.0

Room temperature resistivities of the composites are listed in Table III.

Weight loss at 700°F.	7.0%
T _G No aging post cured.	644°F
T _G aged at 700°F 335 hrs. in nitrogen.	896°F

From the examples it is seen that the process provides material which has structural integrity at temperatures well above the T_G of the parent material. These changes in T_G are shown in FIG. 3. Also, no new processing developments are required to fabricate structures from the material produced by this invention.

The process of the invention provides a method for altering and controlling the electrical resistance of a composite within finite limits that are determined by the parent composite material. These changes are shown in FIG. 4. When coupled with a suitable

protective coating, the material produced in accordance with the present invention can be used at temperatures of 700°F and above for long periods of time.

While the preferred embodiment of the invention has been disclosed and described, it will be appreciated that various modifications may be made to the invention without departing from the spirit thereof or the scope of the subjoined claims.

ABSTRACT OF THE DISCLOSURE

A graphite fiber reinforced polymer matrix is layed up, cured, and thermally aged at about 750°F in the presence of an inert gas. The heat treatment improves the structural integrity and alters the electrical conductivity of the materials. In the preferred embodiment PMR-15 polyimides and Celion-6000 graphite fibers are used.
