NUSAT 1 METHODS FOR RADAR FIELD STRENGTH MEASUREMENT

Paul Talaga

Center for Aerospace Technology, Weber State College, Ogden, UT

Abstract: The methods for obtaining the gain pattern of an Air Traffic Control Radar using the data collected by NUSAT 1 presented. The equations for this are given; these require an independently determined satellite attitude. addition we simultaneous measurements made separate channels can be related to obtain a single axis attitude, i.e., the direction of propagation of the incident radiation, and the power density of the radiation. This is done by solving a system of three algebraic equations.

Introduction. NUSAT 1 was the first satellite to be launched from a Getaway Special Cannister. It has six L-band channels which are driven by six orthogonally directed antennas. The purpose of these systems is to detect Air Traffic Control Radar (ATC) transmissions and measure the power density of the

incident radiation, thus allowing gain pattern of the radar transmitter to bе determined. satellite Since the is floating (no attitude control) since gains οf the satellite's receiving antennas not unidirectional fundamental problem arises in the determination of the direction of propagation (with respect to a satellite based coordinate οf the incident system) radiation. Τo surmount this problem crude а attitude determination system was included in NUSAT 1. It will not give an attitude accurate enough for data reduction.

The purpose of this paper twofold; one, we will present the equations needed to calculate the gain of the radar transmitter and power density of the radar wave. These can bе used if independently determined attitude is available. Two, we will also simultaneous how three measurements made bу three separate channels can be related obtain а single attitude; i.e., the direction of of the propagation incident radiation, and the power density of that radiation. This is done solving a system of three algebraic equations. addition, we will give a short error discussion to indicate the type of accuracy available.

1. Overview of NUSAT 1 For those readers who are unaware of the need and current methods for obtaining the power pattern of an ATC radar, we will give a brief summary of the situation; [1] contains more detailed information.

Air Traffic Control Radar ATC radar transmitting antennas rotate at a rate of one revolution in four to seconds. They have an elevation beam width of about 40 degrees (the lower 15-20 degrees is used detect aircraft) and azimuth beam width of 2 degrees. They transmit on a frequency of 1030 Mhz. If the antenna is pointing too low, then ground interference causes nulls lobes. So for safe operation in controlling air traffic, radiation pattern for different azimuthal orientations of the radar antenna is desired. In lieu of this, at least the location of the nulls and lobes.

The Satellite. The shape of NUSAT 1 is a twenty-six sided polyhedron. Upon launch, the satellite was not given any initial spin, nor is there any attitude control. Thus, the satellite's attitude is allowed to drift.

The satellite has a rather crude attitude determination system - eight symmetrically located wide angle field of view sensors (detecting radiation primarily in the visible region of the spectrum).

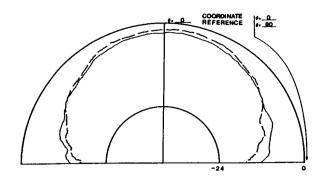

Fig. 1. Partial power gains in the horizontal G_{ϕ} ---- and vertical G_{ϕ} ----.

features οf present interest to us are the six Lband antennas whose major axes are directed in six orthogonal directions. Each is a circularly polarized double Archimedes spiral antenna with a nominal total gain of 1.4 dB. One cut of the pattern (partial power gains in the horizontal and vertical directions) of a typical antenna is depicted in Fig. 1. Note that the usable range is a hemisphere centered about the antenna's major axis and that the gain is down by 6 or 7 dB at 60 degrees. 2. The Basic Equations. calculation used to determine the gain of a radar antenna can be split into two steps. First, the measured value of the received power is used to find the power density of the incident wave at the satellite. Then this value combined with data orbital prediction routines compute the gain of the radar. These calculations are based on the transmission equation.

The fundamental equation governing power transmission is the <u>Friss Transmission Equation</u> [2, Sec 2.17]:

$$P_{r} = (\lambda/4\pi r)^{2}G_{r}(\theta_{r},\phi_{r}) \times G_{t}(\theta_{t},\phi_{t}) peP_{t}$$
 (1)

where

 P_r = power supplied by the receiving antenna,

P_t = power applied to the transmitting antenna,

r = distance between the
 antennas,

e = total efficiency,

p = polarization loss
 factor,

 $G_r(\theta_r, \phi_r)$ = isotropic gain of the receiving antenna in the (θ_r, ϕ_r) direction, $G_t(\theta_t, \phi_t)$ = isotropic gain of the transmitting antenna in the (θ_t, ϕ_t) direction. The relation between these parameters is shown in Fig. 2.

The power density W of the incident electromagnetic wave is related to the received power by

$$W=P_r 4\pi \lambda^{-2} (G_r (\theta_r, \phi_r)_p)^{-1}$$
. (2)

By using this in equation (1), one can show that the desired quantity $G_{t}(\theta_{t},\phi_{t})$, the gain of the radar antenna-ground interference in the direction (θ_{t},ϕ_{t}) , is

$$G_{t}(\theta_{t},\phi_{t}) = 4\pi r^{2} W/P_{te}$$
 (3)

In logarithmic decibel form this becomes

$$[G_t(\theta_t, \phi_t)]_{dB} = 20logr + [W]_{dB} + 10 log(4\pi/eP_t),$$

where the last term may be dropped if the absolute gain is not desired and the quanities P_t , e are nominally constant.

In our application, Pr measured by the satellite; then equation (2) is used calculate W. In (2) the angles θ_{r},ϕ_{r} represent the direction of propagation of incident wave; the direction of the ATC radar in а satellite based coordinate system. These can be from an attitude determination system or they can be computed simultaneously with addition, Ιn polarization loss factor, p,

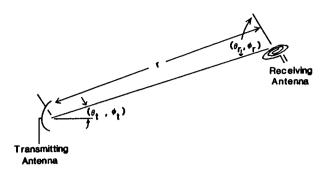

Fig. 2. Relation of parameters for power transmission.

must bе evaluated. evaluation of p and computation of W will be discussed in more detail in the next section. W is found, it can be used in (3) to get the gain of the radar antenna. Here, the variables r, θ_t, ϕ_t are the spherical coordinates of the satellite in a local coordinate system based at the radar antenna. These can be found from orbital prediction routines.

3. Computation of power density and the polarization loss factor. density W power οf incident radar wave is computed using (2). Nominally, the radar wave is linearly polarized and the receiving antennas circularly polarized; so p may be approximated by 1/2. For more accuracy p needs to be evaluated; this may be done using the gain measurements performed on the receiving antennas.

The antennas were measured using a modified version of the Multiple-Amplitude-Component method. The entire gain pattern (letting θ_r , ϕ_r range over useful values, a hemisphere about the major axis) of each antenna was mreasured with а linearly polarized transmitter oriented at angles ψ of 0, 45, 90, and 135 degrees (see Fig. 3). resulted in a measurement of the partial power gains G_{ϕ} , G_{45} , G_{θ} ,

 $^{\rm G}_{135}$ respectively in the direction $(\theta_{\, r}\,,\phi_{\, r})$.

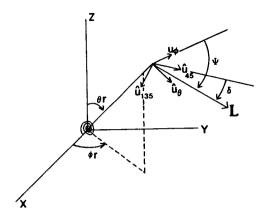

Fig. 3. Direction of polarization, L, of wave propagating from direction (θ_r, ϕ_r) .

Letting L, in Fig. represent the electric field of the incident wave allows the polarization ratio to be related to either of the angles ψ or δ . angle ψ using the assuming that the wave perfectly linear; i.e., that the in the direction perpendicular to L is zero, one can show that

$$p = \cos^2 \psi + \tau^2 \sin^2 \psi + \tau \sin^2 \psi \cos \beta / (1 + \tau^2)$$

where τ, β are the polarization ratio and relative phase angle of the receiving antenna in the direction (θ_T, ϕ_T) . A similar equation is available for pusing the angle δ . Note that for a perfectly circular antenna we have $\cos \beta = 0$ and $\tau = 1$ so that preduces to 1/2. We also note that there is the option of approximateing $\cos \beta$ with a nominal value for each antenna. If this is done, only the measurements G_{ϕ} , G_{θ} need to be performed and

$$\begin{array}{ll} G_r p = G_\phi \cos^2 \psi + G_\theta \sin^2 \psi \\ + \tau \sin 2\psi \cos \beta G_r / (1 + \tau^2) \,. \end{array}$$

Since a complete set of four measurements are available for NUSAT 1, both τ and β can be found for each direction (θ_r, ϕ_r) . Omitting the intermediate steps, we get two different equations to use for the product $G_r(\theta_r, \phi_r)p$ in equation (2). Using the angle ψ we get

$$G_{r}p=G_{\phi}\cos^{2}\psi+G_{\theta}\sin^{2}\psi+$$
 $(1/2)\sin^{2}\psi(G_{45}-G_{135}).$
(4)

Using the angle δ we get

$$G_{r}^{p=G_{45}\cos^{2}\delta+G_{135}\sin^{2}\delta} + (1/2)\sin^{2}\delta(G_{\theta}-G_{\phi}).$$
(5)

If the satellite's attitude can be found, then θ_r, ϕ_r can be determined from the relative location of the radar and the the satellite at time mesasurement was made. Further, ψ and δ can be found by applying the attitude matrix to a vector in the direction of the local vertical at the radar antenna. Thus, $G_r(\theta_r,\phi_r)$ can be determined from either equation (4) or (5). For better accuracy, the equation that has the smallest value for $\sin 2\psi$ or $\sin 2\delta$ should be used (subtraction produces a loss of significance in the third terms).

Alternately, the power density, W, and the angles $heta_{ extsf{r}}, \phi_{ extsf{r}}$ can be simultaneously determined relating three received power For this though, the levels. polarization loss factors must be approximated by 1/2. Recall that NUSAT 1 has six L-band antennas oriented so that their major axes directed in the orthogonal directions. When the satellite is not in a null of the radar's radiation pattern least three channels will be able to detect a signal. The geometry is shown in Fig. 4, where the major axes of the antennas which

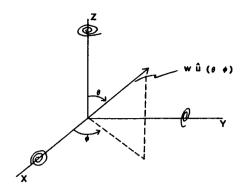

Fig. 4. Three L-band antennas and the direction of the incident wave with power density w.

are able to detect a particular signal have been placed along the x,y,z directions. From equation (2) we have for the three channels:

$$\begin{array}{lll} P_1 &=& (\lambda^2/4\pi)\,G_1(\theta\,,\phi)\,P_1W \\ P_2 &=& (\lambda^2/4\pi)\,G_2(\theta\,,\phi)\,P_2W \\ P_3 &=& (\lambda^2/4\pi)\,G_3(\theta\,,\phi)\,P_3W \end{array}$$

 $G_{i}, P_{i}, p_{i}; i=1,2,3$ are associated with channel i and θ , ϕ give the direction of the radar in body coordinates. If the polarization loss factors are approximated by 1/2 this system can be solved for W, θ, ϕ . The gain functions $G_i(\theta, \phi)$ are known through test measurements, yet any of several numerical methods can be used to solve this system. Ιf the chosen method requires the partial derivatives οf the functions G_i, then it might be necessary to smooth measurements. Actually this system should be solved logarithmic decibel form:

$$\begin{array}{lll} \left[\,P_{\,i}\,\right]_{\,d\,B} &=& 10\log \left(\,\lambda^{\,2}/4\pi\,\right) \\ &+& \left[\,G_{\,i}\left(\,\theta\,\,,\phi\,\right)\,\right]_{\,d\,B} \,+& \left[\,P_{\,i}\,\right]_{\,d\,B} \\ &+& \left[\,W\,\right]_{\,d\,B}\,, & i=1\,,\,2\,,\,3\,. \end{array}$$

Combining each $[P_1]_{dB}$ with $10\log(\lambda^2/4\pi)$ and using P_1 to denote the combined quantity this system becomes, with the dB subscripts dropped

$$P_{1} = G_{1}(\theta, \phi) + W + P_{1},$$

$$P_{2} = G_{2}(\theta, \phi) + W + P_{2},$$

$$P_{3} = G_{3}(\theta, \phi) + W + P_{3}.$$
(6)

For actual computation, each p must be approximated by -3dB.

4. Preliminary error discussion. We now give an error discussion to indicate the origin of major errors and to realize the type of accuracy available. We will only give a short discussion of the errors as the complete error analysis is quite lengthy and is still in the process of being completed.

The gain of the radar antenna in the direction (θ_t, ϕ_t) is computed from (3) with the power density being calculated from (2). From (3), the relative error in $G_t(\theta_t, \phi_t)$ is:

$$\Delta G_{t}/G_{t} = 2\Delta r/r + \Delta W/W + \Delta e/e + \Delta P_{t}/P_{t}.$$

angles $\theta_{\mathsf{t}}, \phi_{\mathsf{t}}$ and distance r are found from orbital prediction routines which usually quite accurate. efficiency e and power supplied to the transmitter P+ are close enough to being constant that they will also not contribute much error. The relative error in the power density $\Delta W/W$ at least two orders magnitude larger than the others. It can be found from (2),

$$\Delta W/W = \Delta P_r/P_r + 2\Delta \lambda/\lambda + \Delta G_r p/G_r p.$$

the received power P_r is obtained from measurements of the signal in the L-band channels. A calibration can be carried out for each channel, thus keeping $\Delta P_r/P_r$ comparatively small. The relative error in the wave length $\Delta \lambda/\lambda$ will be very small, the relative error in neglecting the doppler shift is .01 %. The term

 $G_r(\theta_r,\phi_r)$ will produce the largest error.

error analysis for An or (5) is equations (4) in progress, but no results are available at this time. Αn indication of the error was obtained by considering Gr and p separately. If the angles θ_r, ϕ_r are found independently from W, then the error in $G_r(\theta_r,\phi_r)$ will depend on the errors in θ_r and ϕ_r ; the accuracy of the gain measurements οf the receiving antennas; and variation of G with respect to θ_r, ϕ_r . If the angles θ_r, ϕ_r are known to be within .5 degrees, then $\Delta G_r/G_r$ will be bounded by 12% since the gain measurements indicate that the variation is bounded by .25 dB/deg. Some quick estimates of the error in approximating p by 1/2 indicate that it will average about 1.2dB but may be as high as 2 dB.

Thus, the total error in finding the radar gain $G_t(\theta_t,\phi_t)$ given values of θ_r,ϕ_r accurate to within .5 degrees and approximating p by .5 will be on the order of 1.6 dB but could be as much as 2.3 dB.

To give a preliminary indication of the error in determining $\theta_{\rm T}, \phi_{\rm T}$ and W simultaneously, the author worked several examples. These gave the following bounds:

 $\Delta\theta$, $\Delta\phi \leq 10$ degrees, $\Delta W \leq 1$ dB.

As yet Conclusion satellite has made not any actual radar measurements. Therefore, no test results are available for presentation. But, as reproduced here, the necessary equations are in place for calculating the ATC radar gain in case some measurements are made. These same equations will be needed for the second satellite to attempt an radar calibration, NUSAT2.
