SUMMARY

An investigation of helicopter rotor noise at model scale has been conducted in the Langley 4- by 7-Meter Tunnel. Two rotor systems were used in this program to examine the main-rotor-only noise characteristics in preparation for a complete main rotor/tail rotor interaction study. Each rotor system had several tip configurations in order to select at least one appropriate configuration to use for the main and tail rotor tests. The rotor systems were tested at various operating conditions particularly designed to evaluate the acoustic characteristics of each rotor/tip configuration. Both acoustic and aerodynamic data were acquired during this test; however, only aerodynamic data are presented herein. The acoustic data have been reported elsewhere and properly referenced within.

INTRODUCTION

An investigation of helicopter rotor noise at model scale has been conducted in the Langley 4- by 7-Meter Tunnel. This test was part of an acoustic program designed to develop a data base for main rotor/tail rotor interaction noise studies. The initial plans for the program were to conduct the complete main rotor/tail rotor (MR/TR) effort over a period of time that would require three tunnel entries. Phase I , conducted in the 4- by 7-Meter Tunnel, was a study of main-rotor-only noise characteristics. Two rotor configurations each having the capability for several interchangeable tips were used for this investigation. Phase II, conducted at the United Technology Research Center (UTRC), was a study of tail-rotor-only noise characteristics, with an emphasis on tail rotor/pylon/empennage installation effects. These first two phases were intended to define the main-rotor-alone and tail-rotor-alone noise characteristics in preparation for Phase III of the program. Phase III was designed to utilize the information collected in Phases I and II to select an appropriate set of MR/TR configurations and to obtain an MR/TR acoustic data base. The purpose of this report is to provide a repository of the aerodynamic data collected during Phase I.

The rotor systems used in this investigation (Phase I) were models of the U.S. Army UH-60 and Sikorsky S-76 rotors with several tip configurations. References 1 and 2 present some detailed performance characteristics of the UH-60 and S-76 rotors, respectively, for most of the tip configurations tested. A preliminary report of the acoustic results from Phase I is available in reference 3.

SYMBOLS

The rotor axis system performance data have been resolved in the stability axis system as shown in figure 1.

A_1 lateral cyclic pitch, deg

a_0 coning angle, deg

a_{1s} longitudinal flapping, deg (see fig. 2)

B_1 longitudinal cyclic pitch, deg

b number of blades (4)

b_{1s} lateral flapping, deg (see fig. 2)

c reference chord, in. (see table I)

C_D/σ rotor drag coefficient, $\frac{\text{Rotor drag}}{\rho\pi\Omega^2R^4\sigma}$

C_D^*/σ values of C_D/σ in tables II through X that contain inaccuracies due to thermal drift

C_L/σ rotor lift coefficient, $\frac{\text{Rotor lift}}{\rho\pi\Omega^2R^4\sigma}$

C_Q/σ rotor torque coefficient, $\frac{\text{Rotor torque}}{\rho\pi\Omega^2R^5\sigma}$

C_T/σ rotor thrust coefficient, $\frac{\text{Rotor thrust}}{\rho\pi\Omega^2R^4\sigma}$

FM rotor figure of merit

M_{AT} advancing tip Mach number

r radial position along blade, ft

R rotor blade radius, in. (see table I)

V_∞ free-stream velocity, knots

V_∞^* free-stream velocity for particular rotor configuration where blade-vortex interaction noise is maximum, knots

x,y planform definition coordinates for parabolic tip, in.

α_s rotor shaft axis angle of attack, deg

α_{TPP} rotor tip-path-plane angle of attack, deg

θ_C rotor collective pitch angle, deg

Ω rotor rotational speed, rad/sec

ρ free-stream density, slugs/ft^3

μ rotor advance ratio

σ solidity, $bc/\pi R$

MODEL AND APPARATUS

The general rotor model system (ref. 4) was used in the Langley 4- by 7-Meter Tunnel for this investigation. The fuselage, approximately 0.9 model rotor diameter in length, enclosed the basic model hardware, transmission, and controls for the rotor system. Photographs of the model system in the tunnel test section are shown in figure 3. Models of the UH-60 and the S-76 rotors (0.17 scale and 0.21 scale, respectively) with several interchangeable tip designs each were mounted on a fully articulated hub and used in this test. The dimensional and design characteristics of these two rotor systems are provided in figure 4 and table I. The tip configurations tested are defined in figure 5 with additional details on the parabolic tip for the UH-60 rotor provided in figure 6.

The rotor hub was fully articulated, with cyclic and collective pitch of the blades controlled by a swash plate driven by remotely controlled actuators. Blade flapping and lead-lag angles were measured at the flapping hinge offset. The rotors were driven by two 90-hp electric motors through a shared transmission. The entire system - rotor, transmission, and motor - was mounted on a six-component strain-gauge balance to measure rotor forces and moments. The model was mounted on a special model sting (fig. 3) that permits the angle of attack and angle of sideslip to be varied over wide ranges while the model is maintained at a fixed position in the tunnel.

The Langley 4- by 7-Meter Tunnel may be operated with either an open- or closed-throat test section by raising or lowering the side walls and ceiling. For this investigation the tunnel was operated in the open-throat mode with a floor in place. The rectangular jet entrance to the test chamber is 14.5 ft high and 21.75 ft wide. Acoustic treatment was employed to reduce reflections and improve the acoustic characteristics of the test chamber. Some of this treatment can be seen in figure 3 on the test section floor and in figure 3(b) on the test chamber wall.

TEST PROCEDURES AND CONDITIONS

The two rotor blade configurations had the capability for tip modification. Four tips were selected for the UH-60 and five tips selected for the S-76. (See fig. 5.) Since the purpose of the wind-tunnel investigation was to obtain an acoustic data base, only limited aerodynamic performance data were collected. For each rotor configuration, the original intent was to obtain the basic hover characteristics, run through a detailed acoustic test envelope, and then conduct a limited aerodynamic performance test at low advance ratios for each rotor configuration. For some configurations, the tests were shortened primarily because a tip configuration failed on the rotor blade. The shortened test matrix is reflected in the incomplete run schedule for the aerodynamic and acoustic tests.

The rotor configurations were tested for hover at various levels of rotor rotational speed ranging from 1180 to 1500 rpm. The acoustic data were acquired at two levels of C_T/σ (0.064 and 0.086) for a range of free-stream velocities from 50 to 90 knots, and a range of tip-path-plane angles of attack from -10° to 10°. The limited aerodynamic data were acquired for a range of advance ratios (0.15 to 0.30) and a range of tip-path-plane angles of attack (-6° to 3°). The acoustic data and the aerodynamic data were acquired by different techniques. To obtain the acoustic data the procedure was to select an appropriate C_T/σ, free-stream velocity, and then run through an angle-of-attack sweep at zero flapping in order to bracket the

blade-vortex interaction phenomena as viewed on-line. (See ref. 3.) To obtain the aerodynamic data the procedure was to select an appropriate advance ratio and angle of attack, and then run through a collective (C_T/σ) sweep at zero flapping in order to develop a performance map at each advance ratio and angle of attack. All these tests were conducted at a constant value of rotor rotational speed, except for a few limited cases where the rotor and free-stream velocity were operated at a slightly reduced value but with matched advance ratio, C_T/σ, and angle of attack.

A summary of the run schedule for the aerodynamic tests for the UH-60 and S-76 rotors is provided as follows:

UH-60

Rotor configuration	Run number for μ of -		
	0	0.15	0.20
Standard tip	84, 85	120-128	129-137
Swept tip with standard airfoil	400-403, 405-408	422-427	428-433
Swept tip with new airfoil	500-504	524-532	533-541
Parabolic tip	700-703	723-731	732-740

S-76

Rotor configuration	Run number for μ of -		
	0	0.215	0.30
Standard tip	80-83	214-222	223-228
Anhedral tip	300-303		
Swept tip	600-603		
Tapered tip	800-803	822-827	
Square tip	901-904	917-920	

A summary of the run schedule for the acoustic tests for the UH-60 and S-76 rotors is provided as follows:

UH-60

Rotor configuration	Run number for -		
	C_T/σ = 0.064 (V_∞ vs α_{TPP})	C_T/σ = 0.086 (V_∞ vs α_{TPP})	C_T/σ variation at V_∞^*
Standard tip	109, 112, 116, 117	100-108, 110, 111, 113-115, 118	119
Swept tapered tip with standard airfoil	416, 418	404, 409-415, 417, 419, 420	421
Swept tapered tip with new airfoil	511, 514, 517	505-510, 512, 513, 515, 516, 518, 519, 521, 522	520, 523
Parabolic tip	712, 713, 715	704-711, 714, 716, 717	718

S-76

Rotor configuration	Run number for -		
	C_T/σ = 0.074 (V_∞ vs α_{TPP})	C_T/σ = 0.099 (V_∞ vs α_{TPP})	C_T/σ variation at V_∞^*
Standard tip	205, 208, 211, 233	200-204, 206, 207 209, 210, 212, 230-232, 234	213
Anhedral tip		304-306	
Swept tip	609	604-608, 610-612	
Tapered tip	809, 811, 813	804-808, 810, 812, 814-817, 819-821	818
Square tip	909, 912, 913	905-908, 910, 911, 914, 915	916

The model hub configuration used is representative of a full-scale hub. The data presented in this report have not been adjusted for force and moment contributions due to aerodynamic forces acting on the model rotor hub. The data for free-stream velocities other than zero have been corrected for jet-boundary effects by using the methods described in reference 5. The corrected tunnel free-stream dynamic pressure and flow direction are used to compute all velocity parameters and angles of attack.

Unfortunately, after the test program, an anomaly was detected in the rotor balance data. After thorough evaluation, the axial-force component was found to be biased by as much as 120 lb (0.0125 C_D/σ). This bias was caused by an increase in the temperature of the rotor balance located next to the electric drive motors. Even though no temperature measurements were obtained in the vicinity of the rotor balance, the data indicated that as the motor warmed up during a run the heat transferred to the rotor balance and caused the apparent increase in axial force. Usually, all Langley balances are thermally compensated; however, for this test, the balance was a new design for the NASA designers and thus not properly compensated. The problem has since been corrected; however, the anomaly was still present in the rotor drag component data. Only the rotor axial-force measurement was seriously contaminated in these data, and an attempt was made to account for the drift in the axial-force data. Thermal effects typically cause shifts in both zero readings and sensitivities, however, only the zero shift error can be addressed in this data set. The most straight-forward method of data correction would have been to apply a correction based on temperature; however, since temperature at the balance was not measured that was not possible. Correction based on the time of operation was applied instead.

All the rotor axial-force data from the hover runs were collected into one large data base. A second-order polynomial regression analysis was performed on these axial-force data as a function of time from the start of the motors. Because for a pure hover test the rotor axial force should be near zero, depending on the ability of the pilot to maintain zero flapping, this curve should provide a correction equation that can be applied to the rest of the data at free-stream velocities other than zero. This correction was applied to the raw axial-force data, and then the full data base was recomputed. Since the corrections had to be made as a function of time, there still remains some uncertainty in the accuracy of the axial-force data. Upon review of all the hover data after correction it appears that the uncertainty can be as much as ±25 lb (approximately ±0.0025 C_D/σ). For this reason, the data are being presented in tabular form and no attempt has been made to compare the performance of the various tip configurations. Since there is no way to assure that the rotor axial-force data at free-stream velocities other than zero have been successfully corrected, it is important that the reader be careful in interpreting any results that depend on the rotor axial-force measurements. The only parameter affected, that is presented herein, is C_D/σ, which is labeled C_D^*/σ in tables II through X.

PRESENTATION OF RESULTS

The results of this wind-tunnel investigation are presented herein in tabular form in tables II through X as follows:

In tables II through X, part (a) includes the parameters computed from the data base which basically describe the rotor control operating conditions, whereas part (b) includes the parameters computed from the data base which describe vehicle and tunnel flight simulation parameters.

16. Abstract

An investigation of helicopter rotor noise at model scale has been conducted in the Langley 4- by 7-Meter Tunnel. The program described in this report was the first of a planned three-phase project, whose purpose was to examine the characteristic noise mechanism involved in main rotor/tail rotor interaction noise. This first phase was conducted with a main rotor only in order to identify the characteristic noise generated by only the main rotor. This report defines the aerodynamic operating conditions of the rotor system during the test. The acoustic data are properly referenced.
