SUMMARY

The aerodynamic performance characteristics of an isolated coannular plug nozzle have been investigated in the Langley 16-Foot Transonic Tunnel. Thirty-seven configurations generated by the combination of three geometric variables - plug angle, shroud boattail length (fixed exit radius), and shroud extension length - were tested.

Results of the wind-tunnel test program indicate that axial movement of the shroud exit downstream, which increases the design nozzle pressure ratio, decreased nozzle performance for the nozzle pressure ratios typical of low-bypass-ratio turbojet engines. Scalloping the shroud boattail to simulate retracted noise suppressor hardware had negligible effects on nozzle performance.

INTRODUCTION

The design of propulsion systems for supersonic cruise vehicles (SCV) has received considerable effort since the early 1970's. The coannular plug nozzle, as a general class, has been utilized in many design studies because of its wide applicability to noise abatement schemes (refs. 1 through 3). Noise abatement devices are required in order to meet Federal Aviation Regulations (FAR's) stipulating noise limitations. Typically, these devices impair nozzle efficiency and thereby reduce the overall aerodynamic performance of the vehicle.

The objective of the current investigation was to provide experimental data at transonic speeds, which would allow meaningful trade studies to be conducted between weight, acoustic requirements, and nozzle performance. A similar nozzle investigation has been conducted in the Lewis 8 x 6-Foot Supersonic Wind Tunnel (ref. 4). The data of the current investigation were obtained at Mach numbers from 0.65 to 1.20 and nozzle pressure ratios (NPR) from 1.0 to 10.0. Model angle of attack was nominally maintained at 0° throughout the investigation.

SYMBOLS

The symbols used in the computer-generated tables are given in parentheses.

A	length of cylindrical body extension, cm
A_e	nozzle exit area, m ²
A_m	maximum cross-sectional area, m ²
A_t	nozzle throat area, m ²
B	length of boattail (curvature tangent point to exit), cm
(CFMD)	gross thrust-minus-drag coefficient, $\frac{F - D}{q_\infty A_m}$

C_p		local static-pressure coefficient, $\frac{p - p_\infty}{q_\infty}$
d		model maximum diameter, 15.24 cm
F		gross thrust, positive upstream, N
$F - D$		nozzle gross thrust minus external drag, N
F_i		ideal isentropic gross thrust based on measured mass flow, N
$\frac{F - D}{F_i}$	(FMDZFI)	gross thrust-minus-drag divided by ideal isentropic thrust
l		plug length, cm
M	(MACH)	free-stream Mach number
p		local static pressure, N/m^2
$p_{t,j}$		jet total pressure, N/m^2
$p_{t,j}/p_\infty$	(NPR)	ratio of jet total pressure to free-stream static pressure
p_∞		free-stream static pressure, N/m^2
	(P1-P15)	plug local static pressure divided by jet total pressure
q_∞		free-stream dynamic pressure, N/m^2
R		radius of curvature of plug truncation, cm
	(S1-S10)	shroud local static-pressure coefficient, $\frac{p - p_\infty}{q_\infty}$
w_i		ideal nozzle exhaust flow rate, kg/sec
w_p		measured nozzle exhaust flow rate, kg/sec
x		axial distance of plug pressure orifice location downstream of model station 112.38, cm
y		axial distance of shroud pressure orifice location downstream of model station 125.24, cm
α_p		plug angle, deg

APPARATUS AND METHODS

Wind Tunnel

The investigation was conducted in the Langley 16-Foot Transonic Tunnel, a single-return, atmospheric tunnel with an octagonal slotted-throat test section and continuous air exchange. The tunnel has a continuously variable airspeed up to a Mach number of 1.30. The average Reynolds number per meter varies from 9.71×10^6 at

a Mach number of 0.50 to 12.6×10^6 at a Mach number of 1.30. A complete description of this facility and its operating characteristics can be found in reference 5.

Model and Support System

Photographs of the air-powered nacelle installed in the test section are shown in figure 1. The sting-strut-supported turbojet-engine simulator model used in this investigation is illustrated in the sketch of figure 2. The model consisted of a cone-ogive forebody, a cylindrical section of 15.24 cm diameter, and an afterbody-plug combination consisting of a cylindrical section, a boattail, and a cone plug. The afterbody-plug combinations were detachable at model station 101.60 to facilitate configuration changes. Dry high-pressure air at a stagnation temperature of approximately 520°R was used to simulate the exhaust stream of the turbojet-engine simulator.

The model was supported in the tunnel by a sting-strut support system at the nose as shown in figures 1 and 2. Boundary-layer transition on the model was fixed by a 0.154-cm-wide strip of No. 100 grit at model station 2.54.

Nozzle/Plug Description

The class of nozzle under investigation in this study is a single-flow, truncated conical plug nozzle with a contoured translating shroud (ref. 2). Thirty-seven configurations were generated by the combination of three geometric variables - plug angle, shroud boattail length (fixed exit radius), and shroud extension length. The model hardware consisted of five plugs having angles from 10° to 20°, eight shrouds (boattails), and three shroud extensions. In addition, two shrouds having "scalloped" trailing edges (simulate retracted noise suppressor geometry) were tested. These shrouds were of the same design as two of the basic or "unscalloped" shrouds for comparison purposes. Photographs of the basic and scalloped shrouds installed on the model are shown in figure 1. Sketches showing design details of the shrouds and plugs are presented in figures 3 and 4, respectively. Table 1 presents the three geometric variables, nozzle expansion ratio, and design nozzle pressure ratio (NPR or $p_{t,j}/p_\infty$) for each nozzle configuration tested.

Tests

Tests were conducted in the Langley 16-Foot Transonic Tunnel statically ($M = 0$) and at Mach numbers from 0.65 to 1.20. NPR was varied from 1.0 (jet-off) to 10.0 depending on Mach number. Figure 5 shows a representative NPR operating schedule with Mach number for a low-bypass-ratio engine. Each range of NPR tested at a particular M included a scheduled NPR data point for this Mach number as obtained from figure 5.

Instrumentation and Data Reduction

Data obtained during the investigation were recorded simultaneously on magnetic tape and were reduced to coefficient form by the use of a computer. Approximately 50 frames of data were taken over a time period of 5 seconds for each data point and the average value was used for computations.

A six-component strain-gauge balance was used to measure forces and moments on that portion of the model downstream of the metric break at model station 67.31. (See fig. 2.) Static pressure taps were located on the plug and shroud surfaces as shown in figures 3 and 4. Jet total pressure and temperature were determined from three stagnation pressure probes and two thermocouple measurements, respectively. These measurements were obtained in the nozzle duct downstream of the flow-straightening screens and ahead of the plug support as seen in figure 2. Nozzle mass-flow rate was measured with a turbine-type flowmeter. Corrections were made to the force data to account for bellows/balance interaction tares as outlined in reference 6.

RESULTS AND DISCUSSION

Basic Data

A tabulation of the performance and pressure data for all configurations tested is given in tables 2 through 38. The static ($M = 0$) nozzle discharge coefficient and thrust ratio for configuration 17 are plotted as a function of NPR in figure 6. These data are representative of all configurations, with the results of configuration 17 being arbitrarily picked as the reference configuration for comparison purposes only, and do not represent any critical design condition. Similar results were obtained for all configurations. Since nozzle throat area did not vary with geometric changes, nozzle discharge coefficient (w_p/w_i) remained nearly constant (approximately 0.985) at all test conditions. The annular plug nozzle used in this investigation was operating off-design (overexpanded) at $M = 0$ and $NPR = 2.5$; this results in the low thrust ratio performance shown in the lower half of figure 6.

Wind-On Nozzle Performance

The effect of shroud boattail length B on nozzle performance as a function of NPR is presented in figure 7 at Mach numbers of 0.65 and 0.90. The plug used in this comparison had a 15° angle and an extension ratio A/d of 0.184. Only data for the 15° angle plug configuration are presented as a function of NPR since all the other plugs produced similar results. At the lower nozzle pressure ratios, large losses in performance are indicated as a result of overexpanded nozzle operation. However, as NPR is increased, the thrust-minus-drag ratio increases as the nozzle becomes fully expanded. The large losses shown at the lower NPR are a result of the high expansion ratios for these configurations. (See table 1.) Although varying B would change the boattail radius of curvature and thus have a small effect on drag, its primary effect is to change the nozzle expansion ratio and thrust for a given NPR. Therefore, the vast majority of the differences shown in figure 7 are effects of varying B on A_e/A_t (and thus thrust) and not effects of varying B on drag. The effect of increasing shroud boattail length B on thrust-minus-drag ratio at a representative nozzle pressure ratio for each test Mach number (fig. 5) is presented in figure 8 for three different plug angles. For the 12° and 18° angle plugs, extension length A was also varied. At the subsonic Mach numbers, extending the shroud boattail length (increasing B/d) generally produced a loss in performance for all three plugs similar to that shown in the previous figure. Moving the shroud exit plane further downstream of the throat by increasing extension length (increasing A/d) resulted in a loss of performance which varied from 2 to 6 percent depending on Mach number. At $M = 1.20$, the effect of shroud boattail length on nozzle performance is much smaller. This result is due to the nozzle operating near its design NPR at $M = 1.20$. (See table 1 and fig. 5.)

The effects of extension length on nozzle thrust-minus-drag ratio are presented in figures 9 and 10. As expected from the previous discussion, increasing extension length A produces similar effects on thrust-minus-drag ratio as increasing shroud boattail length B. This result confirms the previous hypothesis that the major effect of increasing shroud length is on thrust (by varying A_e/A_t) rather than on drag (by varying radius of curvature).

The effect of plug angle on nozzle performance for a representative nozzle pressure ratio is shown in figure 11. The plug angle for maximum performance tends to increase with increasing Mach number but this is primarily because NPR is closer to design NPR rather than any special advantage of a particular plug angle.

The effect of nozzle geometry representing a retracted noise suppressor (scalloped shroud) on $(F - D)/F_i$ is presented in figure 12 by comparing scalloped shroud configurations with similar configurations without scalloped shrouds. As shown in this figure, the effect on $(F - D)/F_i$ of scalloping the shroud trailing edge was negligible.

The variation of the plug static-pressure distributions as a function of nozzle pressure ratio for configuration 17 at Mach numbers of 0.65 and 0.90 is presented in figure 13. The plug static-pressure distributions shown in this figure are typical of plug-type nozzles. (See refs. 7 through 9.) The series of increases and decreases of local plug static pressure along the length of the plug are a result of alternating regions of expansion and compression of the jet flow starting with a Prandtl-Meyer expansion fan originating at the shroud lip.

The effect of NPR on the shroud external static pressures for configuration 17 at Mach numbers of 0.65 and 0.90 is shown in figure 14. At $M = 0.65$, the influence of the jet exhaust on the shroud is seen to extend forward to some station ahead of the tangent point ($y/B = 0.0$) of the shroud boattail to the cylindrical section. Jet operation decreased boattail static pressure for all nozzle pressure ratios tested but the data indicate that jet effects may become favorable (increase static pressure) at higher NPR's. At $M = 0.90$, jet operation produced aspiration effects only on the last 50 percent of the boattail surface (jet operation probably moved a standing shock on the boattail down to the nozzle exit). Further increases in NPR had only small effects on the surface static pressures (at y/B greater than 0.65).

Theory

A calculation of the flow field about the nozzle described by the geometry of configuration 17 was carried out at conditions equivalent to $M = 0.95$ and $NPR = 8.60$ using VNAP2 (ref. 10), a computer program which solves the two-dimensional, time-dependent, compressible Navier-Stokes equations. VNAP2 can solve either single- or dual-flowing geometries such as the internal/external flow about inlets and nozzles. For this nozzle calculation, the fluid was assumed to be inviscid and adiabatic and the flow field steady. The computational grid used to calculate the inviscid flow field is presented in figure 15. The grid was designed for high resolution in the region of the jet plume but did not include the truncated base of the plug (fig. 4). The upper surface of the computational grid is a constant pressure inflow-outflow boundary and for this case was 56.7 kN/m^2 (static pressure at $M = 0.95$). The total pressure at the inflow plane was initially set to 0.101 MN/m^2 for the external flow and 0.488 MN/m^2 ($p_{t,j}/p_\infty = 8.60$) for the internal nozzle flow. The total temperature was fixed at 530°R for both regions of the flow.

The computed Mach number contours of the flow field about the nozzle at $M = 0.95$ and $p_{t,j}/p_{\infty} = 8.60$ are shown on figure 16. Presented in figure 17 is a comparison of inviscid adiabatic theoretical calculation of plug pressure distribution with experimental data at a Mach number of 0.95 and nozzle pressure ratio of 8.6.

The Mach number contours of figure 16 show an expansion of the flow downstream of the throat, followed by a strong recompression at the shroud exit. The compression region extends from the shroud lip to approximately $x/l = 0.475$ on the plug. The experimental and computed plug pressure distributions (fig. 17) support this analysis; however, they also clearly illustrate the drawbacks of an inviscid calculation. The experimental data indicate that the flow separates at $x/l = 0.68$, but the VNAP2 calculations show a pressure recovery and no separation over the same region of the plug.

The Mach number contours also illustrate the large velocity gradient between the supersonic jet exhaust and the transonic free stream. The jet plume is roughly defined by the high velocity gradients and indicates that the nozzle is slightly over-expanded. The flow over the shroud boattail is accelerated before encountering a region of strong compression (shock) at the shroud exit plane. The curved sonic line near the throat indicates that the effective nozzle throat area may actually be larger than the geometric throat area. This may explain why the thrust ratios for some configurations approach unity at or near their design nozzle pressure ratios.

CONCLUSIONS

The aerodynamic performance characteristics of a coannular plug nozzle have been investigated in the Langley 16-Foot Transonic Tunnel. Thirty-seven configurations were generated by the combination of plug angle, shroud boattail length (fixed exit radius), and shroud extension length. The results of this investigation indicate the following conclusions:

1. Axial movement of the shroud exit downstream (increasing design nozzle pressure ratio) decreased thrust-minus-drag ratio at test conditions representative of a typical low-bypass-ratio turbojet engine.
2. Scalloping the shroud boattail to simulate retracted noise suppressor geometry had negligible effects on thrust-minus-drag ratio.
3. The flow field about the nozzle can be described by an axisymmetric inviscid, adiabatic fluid model and the plug static pressure predicted so long as the flow remains attached.

16. Abstract An investigation was conducted in the Langley 16-Foot Transonic Tunnel to evaluate the performance characteristics of a coannular plug nozzle at static conditions (Mach number of 0) and at Mach numbers from 0.65 to 1.20. Jet total pressure ratio was varied from 1.0 (jet off) to 10.0. Thirty-seven configurations generated by the combination of three geometric variables - plug angle, shroud boattail length (fixed exit radius), and shroud extension length - were tested.
