## Preface

This is the second in a series of reports presenting results from five extensive lidar flight missions. One of the primary purposes of these missions was to determine the spatial distribution and aerosol characteristics of the El Chichon-produced stratospheric material. This particular mission covered 27°N to 76°N in January to February 1983. The results from the October to November 1982 mission, which covered 46°N to 46°S, were reported by McCormick and Osborn in NASA Reference Publication 1136, *Airborne Lidar Measurements of El Chichon Stratospheric Aerosols—October 1982 to November 1982*. The other three missions took place in July 1982, May 1983, and January 1984 and covered a wide range of latitudes.

This report contains representative profiles of lidar backscatter ratio, plots of integrated backscattering values versus latitude, and contours of backscatter mixing ratio versus altitude and latitude. In addition, tables containing numerical values of the backscatter ratio and backscattering function versus altitude are supplied for each profile. Although no attempt has been made to provide any scientific analysis with the data, this report is intended to give the results of the mission in a ready-to-use format.

The authors recognize the airborne lidar team of W. H. Fuller, Jr., and B. R. Rouse of the NASA Langley Research Center and W. H. Hunt and F. C. Diehl of Wyle Laboratories, whose dedicated efforts provided these data, and wish to thank the crew and supporting personnel at the NASA Wallops Flight Facility for providing excellent research airplane platforms for conducting these measurements. In addition, thanks go to the many groups at the Canadian and Greenland air bases which provided logistics support during this mission. Finally, the authors wish to express their appreciation to D. J. Hofmann and his group at the University of Wyoming for providing the dustsonde data.

## Summary

This report presents lidar data from a flight mission in January to February 1983 between 27°N and 76°N. One of the primary purposes of this mission was to determine the spatial distribution and aerosol characteristics of the El Chichon-produced stratospheric material. Representative profiles of lidar backscatter ratio, plots of integrated backscattering values versus latitude, and contours of backscatter mixing ratio versus altitude and latitude are presented. In addition, tables containing numerical values of the backscatter ratio and backscattering function versus altitude are supplied for each profile. The most massive portion of the material produced by the El Chichon eruptions of late March-early April 1982, which was measured by this flight, resided between 35°N and 52°N. Peak backscatter ratios at a wavelength of 0.6943 μm decreased from 8 to 10 at the lower latitudes to 3 at the higher latitudes. Similarly, the altitudes of the peak scattering ratios decreased from about 20 km to 15 km with increasing latitude. Backscatter ratio profiles taken while crossing the polar vortex show that high-altitude material from El Chichon arrived at the north polar region sometime after the winter polar vortex was established. No attempt has been made in this report to give any detailed explanations or interpretations of the data. The report provides, in a ready-to-use format, the results of this mission to be used in atmospheric and climatic studies.

## Introduction

The late March-early April 1982 eruptions of El Chichon in Mexico (17.3°N, 93.2°W) produced the largest enhancements of stratospheric aerosols in at least 20 years. Because of the effects of the eruption cloud from El Chichon and the need for characterizing the cloud spatially, one of the purposes of the January to February 1983 survey flight was to map its latitudinal distribution. A previous flight mission in October to November 1982 (ref. 1) had shown that this material was well dispersed north and south of the equator, but it was not known how much had reached the polar regions. The January to February 1983 flight mission had two additional objectives: to assist with the SAM II (Stratospheric Aerosol Measurement II) (ref. 2) correlative measurement program and, if possible, to locate and study the scattering characteristics of polar stratospheric clouds. To accomplish these goals, a NASA Electra airplane, outfitted with a lidar system, was flown during the period from January 27 to February 6, 1983, between latitudes of 27°N and 76°N. To assist with the execution of this mission, the SAM II data were made available in real time (approximately 12 hours delay), and a "quick-look" analysis was carried out. In this way, the airborne lidar could be directed to locations of special interest.

This report presents the results of the lidar stratospheric measurements taken over the entire mission. Although the mission failed to locate any polar stratospheric clouds, the other two mission objectives were accomplished. In addition, using real-time SAM II data, the airplane lidar was directed to take measurements while crossing the north polar vortex. More detailed scientific analyses of these results are contained in McCormick et al. (ref. 3).

## Airborne Lidar System

The airborne lidar system used for the measurements presented in this report consists of a ruby laser, nominally emitting 1 joule per pulse at 1 pulse per 2 seconds at a wavelength ( $\lambda$ ) of 0.6943 μm during flight, and a 35.6-cm cassegrainian-configured receiving telescope. Two photomultipliers, electronically switched on at specific times after laser firing, are used to enhance dynamic range. The photomultiplier output signals are processed with an analog-to-digital converter and microprocessor computer, stored on magnetic tape, and displayed on an interactive terminal. The transmitted output divergence is 1.0 mrad, and the receiver field-of-view is 2.0 mrad. Two 40.6-cm quartz windows separated by 1 m are used in the top of the fuselage of the airplane. One window is used for the laser transmitter, and the other, for the telescope receiver. The signal becomes usable at 3 to 4 km above the altitude of the airplane. A detailed error analysis for this system is described in Russell et al. (ref. 4).

## Flight Path

The flight path for the January to February 1983 mission is given in figure 1. The northbound and southbound flight legs are represented by solid lines and dashed lines, respectively. The flight leg on February 1, during which the airplane lidar flew west of Thule and returned along the same path, is represented by a single solid line.

As expected, overlying upper tropospheric clouds prevented measurements at some latitudes, but most latitudes were covered, and a remarkable amount of high-quality data were successfully recorded. Table A1 (in the appendix) contains an abbreviated flight log for the mission and lists the date, time, location, and flight altitude for those legs of the mission where good quality lidar data were obtained.

## Lidar Profiles

The lidar backscatter ratio (or scattering ratio) is defined as

$$R(z) = 1 + \frac{f_A(z)}{f_M(z)} \quad (1)$$

where  $f_A$  is the aerosol backscattering function, or scattering function, and  $f_M$  is the molecular backscattering function, both in units of  $(\text{km}\cdot\text{sr})^{-1}$  and both at altitude  $z$  (ref. 5). Representative vertical profiles of lidar scattering ratio for the flight survey are shown in figures 2 to 31. The error bars reflect the  $1-\sigma$  uncertainty in the derived scattering ratio. The tropopause height is indicated by an arrow. Tables A2 to A31 (in the appendix) contain numerical values of the aerosol scattering ratio and scattering function versus altitude for each of these profiles.

The scattering-ratio profiles, reported at 0.15-km intervals, have been smoothed over 0.3 km. The minimum three-point running average over a specified altitude range was computed for each profile. The profiles were then normalized, so that this minimum was 1, a value which would be obtained only if no aerosols were present at some altitude within the normalization region. Occasionally, the numerical values of the scattering ratio are less than 1, and the corresponding scattering functions are negative. This occurs near the normalization height and when the profile contains minima outside the normalization region. Minimum values of the scattering ratio and scattering function should be considered 1 and 0, respectively.

As shown in figures 2 through 31, the peak scattering ratios at  $\lambda = 0.6943 \mu\text{m}$  decreased from a high of 8 to 10 at the lower latitudes to a low of 3 at  $72^\circ\text{N}$ , before increasing to 6 at  $76^\circ\text{N}$ . Similarly, the altitudes of the peak scattering ratios dropped from about 20 km at  $27^\circ\text{N}$  to about 15 km at  $72^\circ\text{N}$ . Dramatic changes in scattering-ratio profiles (especially above 18 km) were observed on February 1. These occurred because the flight path west of Thule crossed from inside to outside of the north polar vortex. From these profiles it can be inferred that the bulk of the higher altitude volcanic material (originally above 20 km at low latitudes) reached high latitudes sometime after the polar vortex was established. The material originally below about 20 km at low latitudes reached the Arctic region by the end of April 1982 (ref. 3).

## Integrated Backscattering

The integrated aerosol backscattering function is defined as

$$\int_{h_T}^{28 \text{ km}} f_A(z) dz \quad (2)$$

where  $f_A$  is the aerosol backscattering function  $(\text{km}\cdot\text{sr})^{-1}$  at altitude  $z$ , and  $h_T$  is the height of the tropopause at the location where the lidar data were taken. The integrated aerosol backscattering function for all usable lidar data from the January to February 1983 mission, except the February 1 flight leg west of Thule, is plotted in figure 32. The solid lines represent values computed from profiles taken on the northbound flight, and the dashed lines repre-

sent values computed from profiles taken on the southbound flight. The northbound and southbound data, combined and averaged into  $2.5^\circ$  latitude bins, are shown in figure 33. Figures 32 and 33 show that the material produced by the El Chichon eruptions of late March-early April 1982 had moved northward since October 1982 (ref. 6). By January to February 1983, the amount of material at  $75^\circ\text{N}$  was roughly equal to the amount of material at  $30^\circ\text{N}$ , with the most massive portion of material between  $35^\circ\text{N}$  and  $52^\circ\text{N}$ .

## Contours of Backscatter Mixing Ratio

The backscatter mixing ratio is defined as  $f_A/f_M$ , or  $R(z) - 1$ . The symbol  $R(z)$  was defined previously in equation (1). Contours of backscatter mixing ratio were plotted for all the southbound and northbound lidar data to determine the vertical as well as the latitudinal distribution of the El Chichon-produced aerosol. Figures 34 and 35 contain the northbound and southbound contours, respectively. These figures clearly show that the altitude of the peak mixing ratio decreases with increasing latitude.

## Optical Depth and Mass

By using the size distribution and index of refraction data from a six-channel dustsonde launch of January 28, 1983, at Laramie, Wyoming ( $41^\circ\text{N}$ ), an aerosol optical model was constructed. The model gives a conversion value from integrated backscattering to column density of  $20.5 \text{ g}\cdot\text{sr}/\text{m}^2$  (ref. 7).

Similarly, by using the aerosol characteristics determined from the dustsonde flight as representative of the aerosol over the most massive part of the stratospheric cloud, the value for converting integrated backscattering to optical depth was calculated to be 48 sr. Peak optical depth values of about 0.14 at  $\lambda = 0.6943 \mu\text{m}$  were determined at  $45^\circ\text{N}$ . This value is as high as that measured at low latitudes during the October-November 1982 mission (ref. 6).

## Concluding Remarks

This report has presented a summary of the lidar data obtained during the January to February 1983 flight mission. One purpose of this mission was to determine the spatial distribution of the El Chichon-produced stratospheric material. Vertical profiles of aerosol backscatter ratio were determined over the latitudes of the flight ( $27^\circ\text{N}$  to  $76^\circ\text{N}$ ). The peak scattering ratios at a wavelength of  $0.6943 \mu\text{m}$  decreased from a high of 8 to 10 at the lower latitudes to a low of 3 at  $72^\circ\text{N}$ . Similarly, the altitudes of the peak scattering ratios decreased from about 20 km to 15 km with increasing latitude. Dramatic changes in the scattering ratios were observed as the flight path west of Thule crossed the

north polar vortex. These changes indicate that the higher altitude volcanic material had reached the north polar region sometime after the polar vortex was established. Plots of integrated backscattering values versus latitude show the most massive portion of the cloud produced by El Chichon resided between 35°N and 52°N, at least for the material that existed between the flight extremes of this particular mission. Contours of backscatter mixing ratio versus altitude and latitude further describe the latitudinal and vertical distribution of the El Chichon aerosol.

In addition, tables containing numerical values of the backscatter ratio and backscattering function versus altitude have been supplied for each profile. Thus, the lidar data from the mission have been presented in a ready-to-use format for further scientific analysis.

16. Abstract  A NASA Electra airplane, outfitted with a lidar system, was flown in January to February 1983 between the latitudes of 27°N and 76°N. One of the primary purposes of this mission was to determine the spatial distribution and aerosol characteristics of the El Chichon-produced stratospheric material. This report presents the lidar data from that flight mission. Representative profiles of lidar backscatter ratio, plots of the integrated backscattering function versus latitude, and contours of backscatter mixing ratio versus altitude and latitude are given. In addition, tables containing numerical values of the backscatter ratio and backscattering function versus altitude are supplied for each profile. The largest amount of material produced by the El Chichon eruptions of late March–early April 1982, which was measured by this flight, resided between 35°N and 52°N. Peak backscatter ratios at a wavelength of 0.6943 μm decreased from 8 to 10 at the lower latitudes to 3 at the higher latitudes. Backscatter ratio profiles taken while crossing the polar vortex show that the high-altitude material from El Chichon arrived at the north polar region sometime after the winter polar vortex was established. This report presents the results of this mission in a ready-to-use format for atmospheric and climatic studies.		13. Type of Report and Period Covered Reference Publication
