A NEW GLOBAL GEOMORPHOLOGY?

Victor R. Baker University of Arizona Tucson, Arizona

Geomorphology is entering a new era of discovery and scientific excitement centered on expanding scales of concern in both The catalysts for this development include and space. time technological advances in global remote sensing systems, mathemamodeling, and the dating of geomorphic surfaces and tical Even more important are new scientific questions processes. centered on comparative planetary geomorphology, the interaction late Cenozoic tectonism with landscapes, the dynamics of of climatic changes, the influence of cataclysmic processes, the recognition of extremely ancient landforms, and the history of world's hydrologic systems. These questions all involve the feedback relationships with allied sciences that have recently Examples include climatology yielded profound developments. (plate tectonic theory); geo-(climatic modeling); tectonics physics (high-resolution geodetic and gravity surveys, seismic stratigraphy); sedimentology (sedimentary basin analysis); hydro-(hydroclimatic modeling, systems analysis); geochemistry logy (isotopic indicators of environmental change, geochronological chrono-functions); pedology (documentation of techniques); oceanography (detailed mapping of the sea floor); and planetology (discovery of new landscapes on other planets). The intellectual feedback from these associations can generate profound tests of existing geomorphic theory. For example, what are the implicaof ancient channel and valley forms on Mars for the early tions climatic history of that planet? Are regional rates of long-term degradation consistent with sediment accumulation in basins? were global hydrologic conditions associated with full-What What have been the magnitude and frequency of glacial climates? various cataclysmic geomorphic processes through time? Can the ancient terrains extant on the terrestrial planets elucidate the Precambrian history of Earth? Finally, the most signearly ificant scientific questions in applied geomorphology also have a global or regional context. Relevant concerns include the (1) accelerated erosion induced by deforestation, (2) following: the paleogeomorphology of continental margins (the major frontier of petroleum exploration), (3) the hydro-geomorphic consequences of a Carbon Dioxide warming, (4) desertification, and (5) urban landscape metamorphosis. The emergence of a "New Global Geomorphrequire increased work by large interdisciplinary ology" will research teams, greater international cooperation, and an expandphilosophical basis for the science of terrestrial planetary ed surfaces.
