A generalized coordinates form of the penalty finite element algorithm for the three-dimensional parabolic Navier-Stokes equations for turbulent subsonic flows has been derived. This algorithm formulation requires only three distinct hypermatrices, and is applicable using any boundary fitted coordinate transformation procedure. The tensor matrix product approximation to the Jacobian of the Newton linear algebra matrix statement has been derived. The Newton algorithm has been restructured to replace large sparse matrix solution procedures with grid sweeping, using cx-block tridiagonal matrices, where $\alpha$ equals the number of dependent variables. Numerical experiments have been conducted, and the resultant data gives guidance on potentially preferred tensor product constructions for the penalty finite element 3DPNS algorithm.

## INTRODUCTION

The time-averaged, three dimensional Navier-Stokes equations, for steady, turbulent, subsonic flow of a compressible, heat conducting fluid, can be simplified to admit use of an efficient space marching numerical solution procedure under certain restrictions. Baker, et.al. [1] documents the derivation of the simplified, so-called "parabolic Navier-Stokes" equation set using formal ordering arguments. References [2-7] document application of a penalty, finite numerical solution algorithm for the parabolic Navier-Stokes equations for a variety of subsonic flow configurations, including an embedding within an interaction algorithm to impose axial pressure gradient feedback. These results have provided a basic assessment of the accuracy, convergence and versatility aspects of the finite element penalty algorithm, as well as detailed comparison between experimental data and prediction for various turbulent flow geometries.

These numerical predictions have been accomplished using the CMC:3DPNS computer code [8-10] which has evolved and matured principally under support of this contract. With the theoretical construction well verified, the requirement to improve efficiency becomes of next importance. The specific goals of this contract modification were to construct and evaluate a matrix tensor product factorization of the Newton iteration algorithm and to investigate inclusion of an embedded Poisson equation solution procedure. The results of pertinent analyses are documented in this report.

Overview
The basic requirements of a numerical algorithm construction for the three-dimensional parabolic Navier-Stokes (3DPNS) equation set are accuracy, geometric versatility and efficiency. Any theoretical basis, e.g., finite difference, finite volume, finite element, etc., applied to constructing a 3DPNS algorithm ultimately yields the linear algebra statement $\{F\}=\{0\}$, where elements of $\{F\}$ are strongly nonlinear functions of the dependent variable set $q_{\alpha}\left(x_{j}\right)$. Dependent upon the algorithm designer's decisions, members of the set $\mathrm{q}_{\alpha}$ can include density, mean velocity vector, stagnation enthalapy, turbulent kinetic energy, isotropic dissipation function, pressure and/or scalar potential fields and six components of the Reynolds stress tensor.

For the subject finite element penalty algorithm statement, and the 3DPNS equation set, the functional form of the algebra statement is,

$$
\begin{equation*}
\left\{F I\left(k, \lambda, \theta, \Delta x_{1},\{Q I\}\right)\right\}=\{0\} \tag{1}
\end{equation*}
$$

In equation $1, k$ is the polynomial degree of the finite element basis selected to construct the semi-discrete approximation $q_{\alpha}^{h}\left(x_{j}\right)$ to $q_{\alpha}\left(x_{j}\right)$, $\lambda$ is the penalty function scalar multiplier, $\theta$ is the implicitness factor of the downstream integration step $\Delta \mathrm{x}_{1}$, where $\theta \equiv \frac{1}{2}$ is the trapezoidal rule, and $\left\{Q I\left(x_{1}\right)\right\}$ is the array of expansion coefficients of $q_{\alpha}^{h}\left(x_{j}\right)$, evaluated at the node coordinates of the (spatial) discretization $U_{e}^{2}$ of the 3DPNS solution domain $\Omega \equiv R^{2} \times x_{1}$. For all $\theta>0$, equation 1 is a nonlinear algebraic equation system eligible for solution using any of a multitude of (approximation) procedures. These all can be interpreted within the framework of the basic Newton iteration algorithm matrix solution statement.

$$
\begin{equation*}
[J(\{Q I\})]_{j+1}^{p} \quad\{\delta Q I\}_{j+1}^{p+1}=-\{F I\}_{j+1}^{p} \tag{2}
\end{equation*}
$$

where $p$ is the iteration index at step $x_{j+1}$, and

$$
\begin{equation*}
\{Q I\}_{j+1}^{p+1} \equiv\{Q I\}_{j+1}^{p}+\{\delta Q I\}_{j+1}^{p+1} \tag{3}
\end{equation*}
$$

The Jacobian [J] appearing in equation 2, is by definition the square matrix,

$$
\begin{equation*}
[J(\{Q I \cdot\})] \equiv \frac{\partial\{F I\}}{\partial\{Q J\}} \tag{4}
\end{equation*}
$$

where both I and J range $1 \rightarrow 16$.

This contractual project phase initiated evaluation of decisions made in construction of equations $1-4$, as they principally affect algorithm accuracy and efficiency.

Parabolic Navier-Stokes Equations
The three-dimensional parabolic Navier-Stokes (3DPNS) equations are a simplification of the steady, three-dimensional time-averaged Navier-Stokes equations, which in Cartesian tensor conservation form are

$$
\begin{align*}
& L(\rho)=\frac{\partial}{\partial x_{j}}\left[\rho u_{j}\right]=0  \tag{5}\\
& L\left(\rho u_{i}\right)=\frac{\partial}{\partial x_{j}}\left[\rho u_{i} u_{j}+p \delta_{i j}+\rho \bar{u}_{i}{ }_{j}-\sigma_{i j}\right]=0  \tag{6}\\
& L(\rho H)=\frac{\partial}{\partial x_{j}}\left[\rho H u_{j}-u_{i} \sigma_{i j}+\overline{\rho H^{-} u_{j}^{\prime}}-\overline{u_{i}^{\prime} \sigma_{i j}^{\prime}}+q_{j}\right]=0  \tag{7}\\
& L(\rho k)=\frac{\partial}{\partial x_{j}}\left[\rho u_{j} k+\left(C_{k} \frac{k}{\left.\left.\varepsilon \overline{u_{i}^{\prime} u_{j}^{\prime}}-\mu \delta_{i j}\right) \frac{\partial k}{\partial x_{i}}\right]}\right.\right. \\
& +\rho \overline{u_{i}^{j} u_{j}} \frac{\partial u_{i}}{\partial x_{j}}+\rho \varepsilon=0  \tag{8}\\
& L(\rho \varepsilon)=\frac{\partial}{\partial x_{j}}\left[\rho u_{j} \varepsilon+c_{\varepsilon} \frac{k}{\varepsilon} \rho \overline{u_{i} u_{j}} \frac{\partial \varepsilon}{\partial x_{i}}\right]+c_{\varepsilon}^{1} \rho \overline{u_{i} u_{j}} \frac{\varepsilon}{k} \frac{\partial u_{i}}{\partial x_{j}} \\
& +C_{\varepsilon}^{2} \frac{\rho \varepsilon^{2}}{k}=0 \tag{9}
\end{align*}
$$

In equations 5-9 the usual superscript bar notation denoting time-averaged quantities [1l] has been deleted for clarity. The time-averaged dependent variables are density ( $\rho$ ), mean momentum vector ( $\rho u_{i}$ ), pressure ( $p$ ) and stagnation enthalpy $(H)$. Further, $\delta_{i j}$ denotes the Kronecker delta, and the Stoke's stress tensor ( $\sigma_{i j}$ ) and heat flux vector ( $q_{i}$ ) are defined as,

$$
\begin{align*}
& \sigma_{i j} \equiv \frac{\mu}{R e}\left[E_{i j}-\frac{2}{3} \delta_{i j} E_{k k}\right]  \tag{10}\\
& q_{j} \equiv-\kappa \frac{\partial H}{\partial x_{j}} \tag{11}
\end{align*}
$$

where $\mu$ and $k$ are laminar viscosity and heat conductivity respectively. $E_{i j}$ is the symmetric mean flow strain rate tensor.

$$
\begin{equation*}
E_{i j}=\left[\frac{\partial u_{i}}{\partial x_{j}}+\frac{\partial u_{j}}{\partial x_{i}}\right] \tag{12}
\end{equation*}
$$

Finally, $\overline{\mathrm{u}_{i} \mathrm{u}_{j}}$ is the symmetric Reynolds stress tensor with trace equal to $2 k$, where $k$ is the turbulent kinetic energy. For present purposes, $\overline{u_{i}} u_{j}$ is assumed correlated in terms of $k, u_{j}$ and $\varepsilon$, the isutropic dissipation function, in the form,

$$
\begin{equation*}
\overline{u_{i}^{u} u_{j}} \equiv C_{\underline{j}} k \delta_{i j}-C_{4} \frac{k^{2}}{\varepsilon} E_{i j}-C_{2} C_{4} \frac{k^{3}}{\varepsilon^{2}} \cdot E_{i k} E_{k j} \tag{13}
\end{equation*}
$$

where the $C_{\alpha}, 1 \leq \alpha \leq 4$, are known constants [1].

The parabolic approximation to the steady flow Navier-Stokes set, equations $5-13$, is generated by assuming a principal direction of the flow persists, say parallel to the (curvi-linear) coordinate $x_{1}$. Assuming the corresponding mean velocity component $u_{1}$ is of order unity, i.e., $O(1)$, and that the other two orthogonal components $u_{\ell}$ are smaller, say of $0(\delta)$, then for modest density variation the continuity equation 1 confirms that for $\partial / \partial x_{1} \equiv 0(1)$, then $\partial / \partial x_{\ell}=0\left(\delta^{-1}\right)$. Proceeding through the analysis details [12] confirms that the $O(1)$ 3DPNS equation set is

$$
\begin{align*}
& L(\rho)=\frac{\partial}{\partial x_{j}}\left[\rho u_{j}\right]=0  \tag{14}\\
& L\left(\rho u_{1}\right)=\frac{\partial}{\partial x_{j}}\left[\rho u_{1} u_{j}+p \delta_{i j}\right]+\frac{\partial}{\partial x_{\ell}}\left[\rho \overrightarrow{u_{1} u_{\ell}}-\sigma_{1_{2}}\right]=0  \tag{15}\\
& L\left(\rho u_{\ell}\right)=\frac{\partial}{\partial x_{k}}\left[p \delta_{k \ell}+\overrightarrow{\rho \vec{u}_{k} u_{\ell}}\right]=0  \tag{16}\\
& L(\rho H)=\frac{\partial}{\partial x_{j}}\left[\rho H u_{j}\right]+\frac{\partial}{\partial x_{\ell}}\left[\rho \overline{H^{-} u_{\ell}^{-}}-\kappa \frac{\partial H}{\partial x_{\ell}}-u_{i} \sigma_{i \ell}-\overline{u_{i}^{\prime} \sigma_{i \ell}^{\prime}}\right]=0  \tag{17}\\
& L(\rho k)=\frac{\partial}{\partial x_{j}}\left[\rho k u_{j}\right]+\frac{\partial}{\partial x_{\ell}}\left[\left(\rho c_{k} \frac{k}{\varepsilon} \overline{u_{j}^{\prime} u_{\ell}^{\prime}-\mu \delta_{j \ell}}\right) \frac{\partial k}{\partial x_{j}}\right] \\
& +\rho \overline{u_{1}^{\prime} u_{\ell}^{\prime}} \frac{\partial u_{1}}{\partial x_{\ell}}+\rho \varepsilon=0  \tag{18}\\
& L^{i}(\rho \varepsilon)=\frac{\partial}{\partial x_{j}}\left[\rho \varepsilon u_{j}\right]+\frac{\partial}{\partial x_{\ell}}\left[\rho C_{\varepsilon} \frac{k}{\varepsilon} \overline{u_{j}^{\prime} u_{\ell}^{-}} \frac{\partial \varepsilon}{\partial x_{j}}\right]+C_{\varepsilon}^{1} \rho u_{1} u_{\ell} \frac{\varepsilon}{k} \frac{\partial u_{1}}{\partial x_{\ell}} \\
& +c_{\varepsilon}^{2} \rho \varepsilon^{2} / k=0 \tag{19}
\end{align*}
$$

In equations $14-19$ the tensor index summation convention is $1 \leq(i, j) \leq 3$ and $2 \leq(k, \ell) \leq 3$. The Reynolds stress tensor constitutive equation 13 also becomes considerably simplified under the ordering analysis. For example, in rectangular Cartesian coordinates, and retaining the first two orders of terms yields equation 20. An equation of state $\rho=\rho(p, H)$ completes the basic 3DPNS statement.

$$
\begin{align*}
& 0(\%) \\
& 0\left(8^{2}\right) \\
& \overline{u_{1}^{\prime} u_{1}^{\prime}}=C_{1} k-C_{2} C_{4} \frac{k^{2}}{\varepsilon^{2}}\left[\left(\frac{\partial u_{1}}{\partial x_{2}}\right)^{2}+\left(\frac{1 \partial u_{1}}{\partial x_{3}}\right)^{2}\right]-2 C_{4} \frac{k^{2}}{\varepsilon}\left[\frac{\partial u_{1}}{\partial x_{1}}\right] \\
& \overline{u_{2}^{\prime} u_{2}^{\prime}}=C_{3} k-C_{2} C_{4} \frac{k^{3}}{\varepsilon^{2}}\left[\frac{\partial \dot{u}_{1}}{\partial x_{2}}\right]^{2} \quad-2 C_{4} \frac{k^{2}}{\varepsilon}\left[\frac{\partial u_{2}}{\partial x_{2}}\right] \\
& \overline{u_{3}^{\prime} u_{3}^{\prime}}=C_{3} k-C_{2} C_{4} \frac{k^{3}}{\varepsilon^{2}}\left[\frac{\partial u_{1}}{\partial x_{3}}\right]^{2} \\

& -C_{2} C_{4} \frac{k^{3}}{\varepsilon^{3}}\left[\frac{\partial u_{1}}{\partial x_{3}}\left(\frac{\partial u_{2}}{\partial x_{3}}+\frac{\partial \mu_{3}}{\partial x_{2}}\right)\right. \\
& \left.+2 \frac{\partial u_{1}}{\partial x_{2}}\left(\frac{\partial u_{1}}{\partial x_{1}}+\frac{\partial u_{2}}{\partial x_{2}}\right)\right] \\
& \overline{u_{1}^{\prime} u_{3}^{\prime}}=-C_{4} \frac{k^{2}}{\varepsilon}\left[\frac{\partial u_{1}}{\partial x_{3}}\right] \quad-C_{2} C_{4} \frac{k^{3}}{\varepsilon^{3}}\left[\frac{\partial u_{1}}{\partial x_{2}}\left(\frac{\partial u_{2}}{\partial x_{3}}+\frac{\partial u_{3}}{\partial x_{2}}\right)\right. \\
& \left.+2 \frac{\partial \tilde{u}_{2}}{\partial x_{3}}\left(\frac{\partial u_{1}}{\partial x_{1}}+\frac{\partial u_{3}}{\partial x_{3}}\right)\right] \\
& \overline{u_{2}^{\prime} u_{3}^{3}}=\quad-C_{2} C_{4} \frac{k^{3}}{\varepsilon^{2}}\left[\frac{\partial u_{1}}{\partial x_{2}} \frac{\partial u_{1}}{\partial x_{3}}\right] \quad-C_{4} \frac{k^{2}}{\varepsilon}\left[\frac{\partial u_{2}}{\partial x_{3}}+\frac{\partial u_{3}}{\partial x_{2}}\right] \tag{20}
\end{align*}
$$

3DPNS Equation Set Completion
Equations 14-20 do not represent a well-posed, initial-boundary value problem statement for the dependent variable set. In particular, equation 14 is the sole definition for $u_{\ell}$, yielding an underdetermined system. The finite element penalty algorithm construction of Baker [1] yields a wellposed problem statement by inclusion of both $O(\delta)$ transverse momentum equations, definition of an auxiliary harmonic function for a penalty constraint, and definition of complementary and particular solutions to a pressure Poisson equation formed from equation 16.

The derived pressure Poisson equation is,

$$
\begin{equation*}
L(p) \equiv \frac{\partial L\left(\rho u_{\ell}\right)}{\partial x_{\ell}}=\frac{\partial^{2} p}{\partial x_{\ell}^{2}}+\frac{\partial^{2}}{\partial x_{\ell} \partial x_{k}}\left[\overline{\rho u_{k}^{\prime} u_{\ell}^{\prime}}\right]=0 \tag{21}
\end{equation*}
$$

the solution to which is defined as

$$
\begin{equation*}
p\left(x_{i}\right) \equiv p_{C}\left(x_{\ell}, x_{1}\right)+p_{p}\left(x_{\ell}, x_{1}\right) \tag{22}
\end{equation*}
$$

The complementary pressure $\mathrm{p}_{\mathrm{C}}\left(\mathrm{x}_{\ell}, \mathrm{x}_{1}\right)$ is the solution to the homogeneous form of equation 21 with exterior flow boundary conditions [1]. The particular pressure is computed throughout the 3DPNS solution from equation 21, and added in a delayed manner into equation 22 , used in the $u_{1}$ momentum equation solution, yielding a multi-pass interaction algorithm.

The retained $0(\delta)$ transverse momentum equation set is

$$
\begin{equation*}
L^{\delta}\left(\rho u_{\ell}\right)=\frac{\partial}{\partial x_{j}}\left[\rho u_{\ell} u_{j}\right]-\frac{\partial}{\partial x_{k}}\left[\sigma_{k \ell}\right]=0 \tag{23}
\end{equation*}
$$

The auxiliary harmonic variable $\phi$ is defined as the solution to a Poisson equation, driven by the continuity equation 13, in the form

$$
\begin{equation*}
L(\phi) \equiv \frac{\partial^{2} \phi}{\partial x_{\ell}^{2}}-\frac{\partial}{\partial x_{j}}\left[\rho u_{j}\right]=0 \tag{24}
\end{equation*}
$$

Finite Element Penalty Algorithm
As a consequence of the 3DPNS equation set completion, equations 15 , $16+23,17-19,21$ and 24 , define a well-posed, initial-boundary value statement for the dependent variable set $q_{c t}\left(x_{j}\right) \rightarrow\left\{q\left(x_{j}\right)\right\}=\left\{p u_{1}, \rho u_{\ell}, \rho H\right.$, $\left.\rho k, \rho \varepsilon, p_{C}, p_{p}, \phi\right\}$. The equation of state, $\rho=\rho(p, H)$, and equation 20 are algebraic definitions for the remaining seven members $\left\{\rho, \overline{u_{i}^{\prime} u_{j}^{\prime}}\right\}$. Therefore, the first nine members of $\left\{q\left(x_{j}\right)\right\}$ are eligible for constraint on the solution domain boundary, $\partial \Omega \equiv \partial R x_{1}$, by a linear combination of Dirichlet and Neumann boundary conditions of the form

$$
\begin{equation*}
\ell\left(q_{\alpha}\right) \equiv a_{1}^{\alpha} q_{\alpha}+a_{2}^{\alpha} \frac{\partial q_{\alpha}}{\partial x_{\ell}} \hat{n}_{\ell}+a_{3}^{\alpha}=0 \tag{25}
\end{equation*}
$$

In equation 25 , the $a_{j}^{i}$ are defined to enforce the appropriate constraint for each variable, c.f., Baker [2, 12]. Since the remaining seven members of $\left\{q\left(x_{j}\right)\right\}$ are defined by algebraic equations, no boundary conditions are appropriate. Finally, the first six members of $\left\{q\left(x_{j}\right)\right\}$ are required defined on the initial solution plane, $\Omega_{0} \equiv R^{2} \times x_{1}(0)$, by an appropriate initial condition, $\left\{q_{o}\left(x_{\ell}, x_{1}(0)\right)\right\}$.

The complete derivation of the finite element penalty constraint numerical solution algorithm is given in [1, 12]. Briefly, the semidiscrete approximation for each member of the set $q_{i}\left(x_{j}\right)$ is formed by the union of elemental approximations $q^{e}\left(x_{j}\right)$ as,

$$
\begin{equation*}
q_{\alpha}\left(x_{j}\right) \approx q_{\alpha}^{h}\left(x_{j}\right) \equiv u_{e} q_{\alpha}^{e}\left(x_{j}\right) \tag{26}
\end{equation*}
$$

In turn, each elemental semi-discrete approximation, valid on the representative finite element domain $\Omega_{e} \equiv R_{e}^{2} \times x_{1}$, is formed as an expansion on the cardinal basis $\left\{N_{k}\left(x_{\ell}\right)\right\}$, the members of which are (typically) polynominals complete to degree $k$, in the form

$$
\begin{equation*}
q_{\alpha}^{e}\left(x_{j}\right) \equiv\left\{N_{k}\left(x_{\ell}\right)\right\}^{\top}\left\{Q I\left(x_{1}\right)\right\}_{e} \tag{27}
\end{equation*}
$$

In equation 27, $\{\cdot\}$ denotes a column matrix, superscript $T$ its transpose, subscript e denotes pertaining to $R_{e}^{2}$, and the elements of $\{Q I\} e$ are the evaluation of the semi-discrete approximation at the nodal coordinates of $R_{e}^{2}$.

A basic requirement in any algorithm construction is a formal statement regarding constraint on the error formed by employing the semi-discrete approximation for the differential equation set. The finite element algorithm construction requires the semi-discrete approximation error to be orthogonal to the basis employed to construct $q_{a}^{h}\left(x_{j}\right)$. For all members of $\left\{q^{h}\right\}$ except $u_{l}^{h}$, the resultant error constraint statement is,

$$
\begin{equation*}
\int_{R^{2}}\left\{N_{k}\left(x_{\ell}\right)\right\} L\left(q_{\alpha}^{h}\right) d \vec{x}+\beta \int_{\partial R}\left\{N_{k}\left(x_{\ell}\right)\right\} \ell\left(q_{(\ell}^{h}\right) d x \equiv\{0\} \tag{28}
\end{equation*}
$$

where $\beta$ is a scalar multiplier selected to achieve cancellation of the middle term in equation 25 . The error extremization statement for the members $u_{l}^{h}$ of $\left\{q^{h}\right\}$ is,

$$
\begin{align*}
& \int_{R^{2}}^{\{ }\left\{N_{k}\left(x_{\ell}\right)\right\}\left[L\left(u_{\ell}^{h}\right)+L^{\delta}\left(u_{\ell}^{h}\right)\right] d \vec{x}+\beta \int_{\partial R}\left\{N_{k}\left(x_{\ell}\right)\right\} \ell\left(u_{\ell}^{h}\right) d x \\
&  \tag{29}\\
& +\lambda \int_{R^{2}} \frac{\partial\left\{N_{k}\right\}}{\partial x_{\ell}} L\left(\phi^{h}\right) d \vec{x} \equiv\{0\}
\end{align*}
$$

where $\lambda$ is an arbitrary parameter modifying the penalty term which constrains the error extremization by the continuity equation (error).

Equations 28-29 define the finite element penalty algorithm semi-discrete error constraint statement for the 3DPNS equation set. For the non-initialvalued dependent variables, equation 28 yields the linear algebra statement $\{F I\}=\{0\}$, recall equation 1 . For the initial-valued variables, equations 28-29 yield a coupled ordinary differential equation set,

$$
\begin{equation*}
[A] \frac{d\{Q I\}}{d x_{1}}+\{B(Q I)\}=\{0\} \tag{30}
\end{equation*}
$$

which is transformed to a linear algebra statement using a Taylor series, for example,

$$
\begin{equation*}
\{F I\}_{j} \equiv\{Q I\}_{j+1}-\{Q I\}_{j}-\wedge x_{1}\{Q I\}_{j+0}^{\prime}+\cdots=\{0\} \tag{31}
\end{equation*}
$$

where superscript prime denotes the ordinary derivative and $\theta>0$ implies an implicit statement since equation 30 is quite nonlinear.

Hence, the final fully discrete approximation error constraint statement is the nonlinear algebraic equation set,

$$
\begin{equation*}
\left\{F I\left(k, \lambda, \theta, \Delta x_{1},\{Q I\}\right)\right\}=\{0\} \tag{32}
\end{equation*}
$$

where $1 \leq 1 \leq 16$, see equation 1 . The Newton algorithm solution for equation 32 is given in equations 2-4.

## Generalized Coordinates

A basic requirement for a 3DPNS algorithm is geometric versatility, such that the discretization of the transverse plane solution domain $\mathrm{R}^{2}$ can be efficiently embedded within a boundary comprised of the union of select aerodynamic surfaces and freestream interfaces. The term "generalized coordinates" has gained acceptance in describing an algorithm construction suitable for use with a regularizing, boundary fitted coordinate transformation. This construction also impacts directly on the efficiency of an implicit algorithm, since it usually facilitates factorization of the linear algebra statement Jacobian, recall equation 2. An objective of the current project is to construct and evaluate a matrix tensor product approximation to the Newton Jacobian of the finite element 3DPNS algorithm [8].

The required step is to derive the generalized coordinates form of the finite element penalty algorithm, equations 28-29. A multitude of procedures are available to generate regularizing transformations, c.f., [13], and each may be viewed as generating an approximation to the mapping,

$$
\begin{equation*}
x_{i}=x_{i}\left(n_{j}\right) \tag{33}
\end{equation*}
$$

at a finite number of coordinate triples on the domain $\Omega=R^{2} \times x_{1}$. For the space-marched 3DPNS equation set, equation 33 may be conveniently decomposed into an $x_{1}$-oriented grid-stretching transformation, $x_{1}=x_{1}\left(\xi_{j}\right)$, and a regularizing transformation on $\mathrm{R}^{2}$ mapping the boundaries $\partial \mathrm{R}$ onto coordinate surfaces of $\eta_{j}, j=1,2$. Denote the generated set of coordinate pairs on $\mathrm{R}^{2}$ as $\{\mathrm{XI}\}, \mathrm{I}=2,3$. The number of entries in $\{\mathrm{XI}\}$ equals twice the mesh characterization of the discretization $U R_{e}^{2}$ of $R^{2}$. (For example, for a $41 \times 41$ mesh, there are 2(41)(41) = 3362 entries in \{XI\}.) On any (each) finite element domain $R_{e}^{2}$, the specific form of equation 33 is,

$$
\begin{equation*}
x_{i}=\left\{N_{k}(\vec{n})\right\}^{\top}\{X I\} e \tag{34}
\end{equation*}
$$

for $x_{i} \in R_{e}^{2}$. In equation 34 , the elements of $\{X I\}_{e}$ are the appropriate members of $\{X I\}$, and the interpolation basis $\left\{N_{k}(\vec{n})\right\}$ is (potentially) identical to the approximation subspace for $q_{j}^{h}$, equation 27.

Equation 34 is of general utility since the elements of $\left\{N_{k}(\vec{n})\right.$ are well known for $k \geq 1$, using either triangular or quadrilateral shaped finite elements $R_{e}^{2}$, with or without curved sides. The algorithm requirement is to transform the derivatives $\partial / \partial x_{1}$ and $\partial / \partial x_{\ell}$, see equations $15-19,21-24$, as they appear in the penalty algorithm statement, equations 28-29. A grid stretching parallel to the $x_{1}$ coordinate direction introduces additional derivatives in the $x_{\ell}$ plane, upon transformation to the $\zeta_{j}$ coordinate system of the form [8].

$$
\begin{equation*}
\frac{\partial}{\partial x_{1}} \rightarrow \frac{\partial}{\partial \zeta}-h_{2} \frac{\partial}{\partial x_{2}}-h_{3} \frac{\partial}{\partial x_{3}}=\frac{\partial}{\partial \zeta}-h_{\ell} \frac{\partial}{\partial x_{\ell}} \tag{35}
\end{equation*}
$$

Therefore, the general form of the initial-valued partial differential equations $15,16+23,17-19$, of the 3DPNS set is

$$
\begin{equation*}
L\left(q_{\alpha}\right)=\frac{\partial}{\partial \zeta}\left[u_{1} q_{\alpha}\right]+\frac{\partial}{\partial x_{\ell}}\left[\left(1-h_{\ell}\right) q_{\alpha} u_{\ell}+\tau_{\alpha \ell}\right]+s_{c:}=0 \tag{36}
\end{equation*}
$$

Table 1 lists $q_{\alpha}, \tau_{\alpha \ell}$, and $s_{\alpha}$ for $1 \leq \alpha \leq 6$ in equation 36 , and $2 \leq \ell \leq 3$.

Table 1. Variables and Parameters in Equation 36

The generalized coordinates construction requires transformation of the planar divergence operator $\partial / \partial x_{\ell}$, when equation 36 is inserted into equation 28. Using a Green-Gauss form of the divergence theorem on the second term in equation 36 , yields

$$
\begin{align*}
\int_{R^{2}}\left\{N_{k}\right\} L\left(q_{\alpha}^{h}\right) d \vec{x} & +\beta \int_{\partial R}\left\{N_{k}\right\} \ell\left(q_{\alpha}^{h}\right) d \sigma=\int_{R^{2}}\{N\}\left[\frac{\partial}{\partial \zeta}\left(u_{1}^{h} q_{\alpha}^{h}\right)+s_{\alpha}^{h}\right] d \vec{x} \\
& +\oint_{\partial R}\{N\}\left[\left(1-h_{\ell}\right) q_{\alpha}^{h} u_{l}^{h}+\tau_{\alpha l}^{h}\right] \hat{n}_{\ell} d \sigma \\
& -\int_{R^{2}} \frac{\partial\{N\}}{\partial n_{k}} \frac{\partial n_{k}}{\partial x_{l}}\left[\left(1-h_{\ell}\right) q_{\alpha}^{h} u_{l}^{h}+\tau_{\alpha \ell}^{h}\right] d \vec{x} \\
& +\beta \int_{\partial R}^{\{N\}\left[\dot{a}_{1}^{\alpha} q_{\alpha}^{h}+a_{2}^{\alpha} \frac{\partial q_{\alpha}^{h}}{\partial n_{k}} \frac{\partial n_{k}}{\partial x_{l}} \hat{n}_{\ell}+a_{3}^{\alpha}\right] d \sigma}  \tag{37}\\
&
\end{align*}
$$

The evaluation of equation 37 is accomplished by performing the integrals on an element-by-element basis, and assembling the resultant contributions into $\{F I\}$ using the matrix assembly operator $S_{e}, c . f .,[12, C h .2]$. Since the elements of $\left\{N_{k}(\vec{n})\right\}$ are known functions of $\vec{n}$, the only requirement is evaluation of $\partial n_{k} / \partial x_{\ell}$ on a generic finite element domain $R_{e}^{2}$. From equation 34 , the $2 \times 2$ square matrix defining the Jacobian of the forward transformation is

$$
\begin{equation*}
[J]_{e}=\left[J\left(\{X I\}_{e}\right)\right] \equiv\left[\frac{\partial x_{\ell}}{\partial n_{k}}\right]_{e} \tag{38}
\end{equation*}
$$

Thus, the elements of the inverse transformation Jacobian are,

$$
\begin{equation*}
\left[\frac{\partial n_{k}}{\partial x_{l}}\right]_{e}=[J]_{e}^{-1}=\frac{1}{\operatorname{det} J_{e}}[c]_{e} \tag{39}
\end{equation*}
$$

where [C] is the $2 \times 2$ transformed cofactor matrix of [J], the elements of which are algebraic functions of $n_{k}$ and $\{X I\}_{e}$. The differential element $d \vec{x}$ in equation 37 becomes

$$
\begin{equation*}
d \vec{x}=\operatorname{det} J_{e} d \vec{n} \tag{40}
\end{equation*}
$$

Finally, it is convenient to define the contravariant components of the convection velocity semi-discrete approximation $\bar{u}_{k}^{e}$ on $R_{e}^{2}$ as

$$
\begin{equation*}
\bar{u}_{k}^{\mathrm{e}} \equiv \operatorname{det} J_{e}\left[\frac{\partial n_{k}}{\partial x_{l}}\right]_{e}\left(1-h_{\ell}\right) u_{\ell}^{\mathrm{e}}=\left(1-h_{\ell}\right)[C]_{k \ell}^{\mathrm{e}} u_{\ell}^{\mathrm{e}} \tag{41}
\end{equation*}
$$

With equations 38-41, and recasting evaluation of equation 37 as the assembly of integrals over $U R_{e}^{2}$, the generalized coordinates form of the finite element algorithm statement, equation 28 , becomes

$$
\int_{R_{2}}\left\{N_{k}(\vec{n})\right\} L\left(q_{\alpha}^{h}\right) d \vec{x}+\beta \int_{\partial R}\left\{N_{\kappa}(\vec{n})\right\} \ell\left(q_{\alpha}^{h}\right) d \sigma
$$

$$
=S_{e}\left[\int_{R_{e}^{2}} \operatorname{det} J_{e}\{N\}\{N\}^{T}\left(\frac{d}{d \zeta}\{U 1 Q I\}_{e}+\{S I\}_{e}\right) d \vec{\eta}\right.
$$

$$
\begin{aligned}
& -\int_{R^{2}}\{\text { UBARK }\}_{e}^{\top}\{N\} \frac{\partial}{\partial n_{k}}\{N\}\{N\}^{\top}\{Q I\} e^{\vec{n}} \\
& -\int_{R_{e}^{2}}\{E T A K L\}_{e}^{\top}\{N\} \frac{\partial}{\partial n_{k}}\{N\}\{N\}^{\top}\{T A U I L\} e d \vec{n}
\end{aligned}
$$

$$
+\kappa \int_{\partial R}\{N\}\left[a_{1}^{4} q_{4}^{e}+a_{3}^{4}\right] \operatorname{det} J_{e} d \sigma
$$

$$
+\oint_{\partial R}\{N\}\left[\left(1-\underline{h}_{\ell}\right)\{U L\}^{\top}\{N\}\{N\}^{\top}\{Q I\} e\right.
$$

$$
\begin{equation*}
\left.\left.+\{N\}^{T}\{T A U I L\} \text { e } \hat{\eta}_{L} \operatorname{det} J_{c}\right\} d c\right] \tag{42}
\end{equation*}
$$

In writing equation 42 , it has been assumed the only variable possessing a constrained normal derivative boundary condition is stagnation enthalpy. Hence, the fourth term contains only $q_{4}^{e}$, and the normal derivative term in equation 25 is cancelled by the corresponsing term in the third integral in equation 38 by defining $\beta \equiv \kappa$, see Table 1 . A second assumption is that jet $J_{e}$ is adequately represented as an elemental scalar, which is a commission of interpolation error (only) on a sufficiently refined mesh. The elements of the direction cosine matrix \{ETAKI\} $e$ are defined by the interpolation.

$$
\begin{equation*}
\left[\frac{\partial \eta_{\ell}}{\partial x_{k}}\right] \equiv \frac{1}{\operatorname{det} J_{e}}\left\{N_{k}\right\}^{\top}\{\operatorname{ETAKL}\}_{e} \tag{43}
\end{equation*}
$$

For example, defining $k=1$ in equation 43, for the bilinear tensor product basis on straight-sided quadrilaterals, numbering nodes counter clockwise, and defining the elements of the nodal array $\{X I\}$ $1 \leq J \leq 4\}$ e the four arrays $2\left\{\right.$ ETAKL $e_{\text {e }}$ are, c.f., [12, Ch. 8].

$$
2\{E T A K L\}_{e}=\left\{\begin{array}{c}
Z 4-Z 1  \tag{44}\\
Z 3-Z 2 \\
Z 3-Z 2 \\
Z 4-Z 1 \\
(2,2)
\end{array}\right\}\left\{\begin{array}{c}
Y 1-Y 4 \\
Y 2-Y 3 \\
Y 2-Y 3 \\
Y 1-Y 4 \\
(2,3)
\end{array}\right\},\left\{\begin{array}{c}
Z 1-Z 2 \\
Z 1-Z 2 \\
Z 4-Z 3 \\
Z 4-Z 3 \\
(3,2)
\end{array}\right\},\left\{\begin{array}{c}
Y 2-Y 1 \\
Y 2-Y 1 \\
Y 3-Y 4 \\
Y 3-Y 4 \\
(3,3)
\end{array}\right\}
$$

The indices in the parenthesis in equation 44 denote ( $K, L$ ). Finally, the matrix elements of \{UBARK\} e are defined by the interpolation.

$$
\begin{equation*}
\mathrm{U}_{\mathrm{k}}^{-\mathrm{e}} \equiv\left\{\mathrm{~N}_{\mathrm{k}}\right\}^{\top}\left\{\text { UBARK }{ }_{e}\right. \tag{45}
\end{equation*}
$$

Proceeding through the algebra yields

$$
\begin{equation*}
\{U B A R K\}_{e}=\{E T A K L\}_{e}\left\{N_{k}\right\}^{\top}\{U L\}_{e} \tag{46}
\end{equation*}
$$

Since the evaluation of equation 46 is at nodes, the elements of $\left\{N_{k}\right\}$ reduce to the Kronecker delta; hence, $\left\{N_{k}\right\}^{\top}\{U L\}$ simply selects the correct nodal value out of the elemental arrays $\{U L\}_{e}, L=2,3$.

In equations 42-46, the indices $K$, $L$ are tensor summation indices, while $I$ denotes the appropriate member of $\left\{q_{k}^{h}\right\}$. Every matrix denoted by a subscript $e$ in equation 42 is independent of the $\vec{\eta}$ coordinate system spanning $R_{e}^{2}$, hence can be extracted outside the integral. The expressions remaining within the integrand are polynomials on $\vec{n}$, for all definitions of completeness $k$ of the semi-discrete approximation, recall equations 26-27. The order of $\left\{N_{k}\right\}$ depends upon $k$, as do all the integrels in equation 42 , and each is readily evaluated using numerical quadrature. The basic structure of equation 42 is thus defined, using a standardized hypermatrix nomenclature [12], as

$$
\begin{align*}
& \int_{R^{2}}\left\{N_{k}\right\} L\left\{q_{\alpha}^{h}\right\} d \vec{x}+\beta \int_{\partial R}\left\{N_{k}\right\} \ell\left(q_{\alpha}^{h}\right) d \sigma \\
& =S_{e}\left[\operatorname{det} J_{e}[B 200] \frac{d}{d \zeta}\{U 1 Q I\} e+\operatorname{det} J_{e}[R 200]\{S I\}_{e}\right. \\
& -\left(\{\text { UBARK }\}_{e}^{\top}[B 30 K O]-\left(1-h_{k}\right) \hat{n}_{K} \operatorname{det} J_{e}\{U K\}_{e}^{\top}[A 3000]\right)\{Q I\}_{e} \\
& -\left\{\{E T A K L\}_{e}^{\top}[B 30 K 0]-\hat{n}_{L} \operatorname{det} J_{e}[A 200]\{T A U I L\} e\right. \\
& \left.+\kappa \delta_{I 4} \operatorname{det} J_{e}\left[a_{1}^{4}[A 200]\{Q I\} e+a_{3}^{4}\{A 10\}\right)\right] \equiv\{0\} \tag{47}
\end{align*}
$$

Note that equation 47 is in the form of equation 30 , with the definition $[A] \equiv S_{e}\left[\operatorname{det} J_{e}[B 200]\right]$. The generalized coordinates finite element penalty algorithm involves definition of only three distinct standard matrices, [B200] and [B3OKO], $K=2,3$, on $R_{e}^{2}$. These are independent of $R_{e}^{2}$ and depend only on the degree $k$ of the semi-discrete approximation. In addition, there are the three standard matrices [A200], [A3000] and \{A10\}, defined on the boundary of $R^{2}$, hence evaluated on a one-dimensional element $R_{e}^{1}$. In the second and third lines of equation 47 , the terms involving [ $A \cdots$ ] are the residuals from use of the Green-Gauss theorem, see equation 37 . The terms in the fourth line result from the heat convection boundary condition for stagnation enthalpy. The tensor indices range $2 \leq(K, L) \leq 3$, the subscript $\underline{k}$ takes on the value of $K, \hat{n}_{K}$ and $\hat{n}_{L}$ are unit normal vectors to $R^{2}$, and $1 \leq I \leq 16$ denotes the ordered members of the dependent variable array. Finally, det $J_{e}$ is the average value on $R_{e}^{2}$ of the determinant of the transformation Jacobian, equation 38 , and \{ETAKL\} $e$ and \{UBARK\} $e$ are element dependent matrices defined in equations 43-46. The Appendix lists the defined matrices [A . .] and [B. .]. for $k=1$ in equation 27.

## Tensor Matrix Product Jacobian

The form of equation 47 is well suited to formation of a tensor (outer) matrix product approximation to the Newton iteration algorithm Jacobian, see equations 2 and 4 , upon definition and use of a tensor product cardinal basis $\left\{N_{k}^{+}\right\}$, equation 34, on quadrilateral finite element domains $R_{e}^{2}$ (which could be curved-sided, $k>1$ ). In this instance, the Newton algorithm Jacobian is approximated by the tensor matrix product construction,

$$
\begin{equation*}
[J(\{Q I\})] \Rightarrow\left[J_{2}\right] \otimes\left[J_{3}\right] \tag{48}
\end{equation*}
$$

where $\otimes$ denotes the outer product [14]. Equation 2 then becomes of the form

$$
\begin{equation*}
\left[J_{2}\right] \otimes\left[J_{3}\right]\{\delta Q I\}=-\{F I\} \tag{49}
\end{equation*}
$$

Making the definition $\left[\mathrm{J}_{3}\right]\{\delta Q \mathrm{I}\} \equiv\{\delta \mathrm{PI}\}$, equation 49 is solved by sweeping the mesh parallel to $n_{2}$, to determine $\{\delta P I\}$, and then sweeping the mesh parallel to $n_{3}$ to complete the solution, i.e.,

$$
\begin{align*}
& {\left[J_{2}\right]\{\delta P I\}_{\mathrm{e}}=-\{F I\}_{\mathrm{e}}} \\
& {\left[J_{3}\right]\{\delta Q I\}_{\mathrm{e}} \equiv\{\delta P I\}_{\mathrm{e}}} \tag{50}
\end{align*}
$$

The attraction of the approximate solution statement, equation 50 , is replacement of the large sparse matrix [J], equation 4, by two block tri- or penta-diagonal matrices $\left[J_{\eta}\right]$, with the corresponding significant reduction in computer storage and LU decomposition computer CPU time. The detraction of the statement is degradation of the convergence rate associated with the exact Newton algorithm statement. Of course, for the 16 -dependent variable 3DPNS equation set it is impossible to construct and use the exact Jacobian. Hence, the trade-off is degree of approximation versus associated cost. The critical measure is convergence rate since this determines the number of passes through the linear algebra statement.

## Study Problem Statement

The tensor matrix product approximation to the 3DPNS Newton Algorithm Jacobian is formed by evaluation of the appropriate integrals in $\partial\{F I\} / \partial\{Q J\}$
on a one-dimensional domain $R_{e}^{1}$. The CMC:3DPNS code [10] was reorganized to permit construction of a one-dimensional Jacobian, independent of the subroutines used to generate $\{F I\}$. The basic issue is convergence, and the study problem is solution of the 2DPNS equations for laminar and/or turbulent flow. The code was indexed to permit use of the original algorithm formulation, as well as several variants of the tensor product construction. The 2DPNS algorithm construction for turbulent flow using the $k-\varepsilon$ closure with a Reynolds stress algebraic model was established, however, the detailed discussion is limited to the equation system for laminar isoenergetic flow.

The governing 2DPNS differential equation system, see equation 36 , for $\{q\}=\{u, v, p, \phi\}$, is

$$
\begin{align*}
& L(u)=\frac{\partial}{\partial x}(u u)+p^{\prime}+\frac{\partial}{\partial y}\left(v u-\frac{v}{\operatorname{Re}} \frac{\partial u}{\partial y}\right)=0  \tag{51}\\
& L^{\delta}(v)=\frac{\partial}{\partial x}(u v)+\frac{\partial}{\partial y}\left(v v+\frac{p}{p}-\frac{v}{\operatorname{Re}} \frac{\partial v}{\partial y}\right)=0  \tag{52}\\
& L(p)=\frac{\partial}{\partial y}\left[\frac{1}{\rho} \frac{\partial p}{\partial y}+u-\frac{\partial v}{\partial x}+v \frac{\partial v}{\partial y}-\frac{1}{\operatorname{Re}} \frac{\partial}{\partial y}\left(v \frac{\partial v}{\partial y}\right)\right]=0  \tag{53}\\
& L(\phi)=\frac{\partial^{2} \phi}{\partial y^{2}}-\frac{\partial u}{\partial x}-\frac{\partial v}{\partial y}=0 \tag{54}
\end{align*}
$$

In equation 51, $p^{\prime} \equiv \frac{1}{\rho} \frac{d p}{d x}$ is an input parameter (corresponding to the $p_{C}\left(x_{1}, x_{\ell}\right)$ solution, equations 21-22, for 3DPNS). Inserting equations 51-54 into the finite element penalty algorithm, equations 28-29, see equation 42 , proceeding through the algebra, equation 47, and inserting the results for $u^{h}$ and $v^{h}$ into the trapezoidal rule $\left(\theta=\frac{1}{2}\right)$ form of equation 31 , equation 32 becomes the set.

$$
\begin{align*}
\{F 1\} \equiv{\underset{e}{e}}_{S\{F U\}_{e}}= & \underset{e}{S}\left[\frac{1}{2} \Delta_{e}\left\{U_{j+1}^{p}+U_{j}\right\}_{e}^{\top}[A 3000]\left(\{U\}_{j+1}^{p}-\{U\}_{j}\right)\right. \\
& +\frac{\Delta x}{2}\left[\{V\}_{e}^{\top}[A 3001]\{U\}_{e}+\Delta_{e}^{\left\{P^{\prime}\right\}_{e}}+\frac{1}{\Lambda_{e}}\{N U\}^{\top}[A 3011]\{U\}\right)_{j+1, j} \tag{55}
\end{align*}
$$

$$
\begin{align*}
& \{F 2\} \equiv \underset{e}{S}\{F V\}_{e}=\underset{e}{S}\left[\frac{1}{2} \Delta_{e}\left\{U_{j+1}^{p}+U_{j}\right\}_{e}^{T}[A 3000]\left(\{V\}_{j+1}^{p}-\{V\}_{j}\right)\right. \\
& +\frac{\Delta x}{2}\left\{[V\}_{e}^{\top}[A 3001]\{V\}_{e}+\frac{1}{\rho}[A 201]\{P\}_{e}\right. \\
& \left.+\frac{1}{\Delta_{e}}\{N U\}_{e}^{\top}[A 3011]\{V\}_{e}\right)_{j+1, j} \\
& \left.+C_{\phi}\left\{[U]_{e}[A 201]\left\{S_{\phi}\right\}_{e}\right\}_{j+1}\right]  \tag{56}\\
& \{F 3\} \equiv{\underset{e}{e}}\{F P\}_{e}=\underset{e}{S}\left[\frac{1}{\rho \Delta_{e}}[A 211]\{P\}_{e}+\frac{1}{E u}\{U\}_{e}^{T}[A 3010]\{V P\}_{e}\right. \\
& \left.+\frac{1}{E u \Delta_{e}}\{V\}_{e}^{T}[A 3011]\{V\}_{e}\right]_{j+1}  \tag{57}\\
& \{F 4\} \equiv S_{e}\{F \phi\} e=\underset{e}{S}\left[\frac{1}{\Delta_{e}}[A 211]\{\phi\} e+\Delta_{e}[A 200]\{U P\} e+[A 201]\{V\}\right]_{j+1} \tag{58}
\end{align*}
$$

The newly defined standard matrices [A••] are also listed in the Appendix. Further, det $J_{e} \equiv \Delta_{e}$, the measure of $R_{e}^{1}$, and its occurrence has been cleared throughout equations 55-58, such that [A…] are integer arrays with a common divisor. The continuity equation has been explicitly employed to clear extra terms in equations $55-56,\{\cdot\}_{j+1}^{p}$ denotes evaluation with the current iterate at $x_{j+1},\{\cdot\}_{j}$ denotes the converged solution at the previous step $\left(x_{j}\right)$, $(\cdot)_{j+1, j}$ indicates evaluation with both $\{\cdot\}_{j+1}^{p}$ and $\{\cdot\}_{j}$, followed by addition, and $[\cdot]_{j+1}$ denotes evaluation with $\{\cdot\}_{j+1}^{p}$. The arrays $\{U P\}_{e}$ and $\{V P\}_{e}$ contain a finite difference approximation for $\frac{d}{d . \zeta}\{U\} e$ and $\frac{d}{d \zeta}\{V\}_{e}$, evaluated at $x_{j+1}$. The elements of $\{N U\}$ e are $v / R e$, where $\operatorname{Re}$ is the Reynolds number, Eu is
the Euler number, and $\left\{P^{\prime}\right\} e^{\prime}$ contains $\frac{1}{\rho} \frac{d p}{d x}$.
The last term in equation 56 is the continuity constraint penalty term, the selected form of the $\lambda$-modified integral in equation 29. $C_{\phi}$ is a constant of order unity, and $[U\rfloor_{e}$ is a diagonal matrix with elements taken from $\{U\}$ in the same order. (This multiplier improves the resolution of \{V\} in the lower reaches of the boundary layer. The penalty term dependent variable is $\left\{S_{\phi}\right\}_{e}$, defined as the sum of the previous solutions to equation 58 at step $x_{j+1}$, i.e.,

$$
\begin{align*}
&\left\{S_{\phi}\right\}_{j+1}^{p+1} \equiv\left\{S_{j}\right\}_{j+1}^{p}+\left\{\begin{array}{c}
\{\phi\}_{j+1}^{p+1} \\
\end{array}\right. \\
&=\left\{S_{\phi}^{p}\right\}_{j+1}^{p}+\left(\{\phi\}_{j+1}^{p}+\{\delta \phi\}_{j+1}^{p+1}\right) \\
&=\{S \phi\}_{j+1}^{p-1}+\left(\{\phi\}_{j+1}^{p-1}+\{\delta \phi\}_{j+1}^{p}\right) \\
&+\left(\{\phi\}_{j+1}^{p}+\{\delta \phi\}_{j+1}^{p+1}\right), \text { etc. } \tag{59}
\end{align*}
$$

Furthermore, $\{S \phi\}_{j+1}^{\}} \equiv\{S \phi\}_{j}$, which is the identification as well for the first estimate of the dependent variable set, i.e., $\{Q I\}_{j+1} \equiv\{Q I\}_{j}$. This definition of $\{S \phi\}$, as the penalty variable, is a considerable modification of the orginal algorithm construction in CMC:3DPNS, to permit solution for $\{\delta \phi\}$ within equation 2, rather than a separate Poisson solution for $\{\phi\}$.

Equations 55-59 constitute the linear algebra specification of the 2DPNS algorithm. The Newton algorithm Jacobian matrices are derived from the definition, equation 4, using equations 55-58. They are identical to the factor $\left[\mathrm{J}_{2}\right]$ of the tensor product approximation for the 3DPNS statement,
equation 50. Recalling that $[J] \equiv \mathrm{S}_{\mathrm{e}}[\mathrm{J}]$, the elemental components of the 4-block, tridiagonal Jacobian $\left[\mathrm{J}_{2}\right]$ are:

$$
\begin{align*}
& {[J U U]_{e}=\Delta_{e}\{U\}_{e}^{\top}[A 3000]+\frac{\Delta x}{2}\left[\{V\}_{e}^{\top}[A 3001]+\frac{1}{\Delta_{e}}\{N U\}_{e}^{\top}[A 3011]\right]} \\
& {[J U V]_{e}=\frac{\Delta x}{2}\{U\}_{e}^{\top}[A 3100]} \\
& {[J U P]_{e}=[0]} \\
& {[J U \phi]_{e}=[0]} \tag{60}
\end{align*}
$$

$$
\begin{aligned}
{[J V V]_{e}=\frac{1}{2} \Delta_{e}\left\{U_{j+1}^{p}\right.} & \left.+U_{j}\right\}_{e}^{\top}[A 3000] \\
& +\frac{\Delta x}{2}\left[\{V\}_{e}^{T}([A 3001]+[A 3100])+\frac{1}{\Delta_{e}}\{N U\}_{e}^{\top}[A 3011]\right]
\end{aligned}
$$

$$
[J V U]_{e}=\frac{1}{2} \Delta_{e}\left\{V_{j+1}^{p}-V_{j}\right\}_{e}^{T}[A 3000]
$$

$$
[J V P]_{e}=\frac{\Delta_{e}}{2 \rho}[A 201]
$$

$$
\begin{equation*}
[J V \phi]_{e}=C_{\phi}[U]_{e}[A 201] \tag{61}
\end{equation*}
$$

$$
[\mathrm{JPP}]_{\mathrm{e}}=\frac{1}{\rho \Delta_{\mathrm{e}}}[\mathrm{~A} 211]
$$

$$
[J P U]_{\mathrm{e}}=\frac{1}{E u}\{V P\}_{\mathrm{e}}^{\top}[\mathrm{A} 3010]
$$

$$
[J P V]_{e}=\frac{a}{E u}\{U\}_{e}^{\top}[A 3010]+\frac{1}{E u \Delta_{e}}\{V\}_{e}^{\top}([A 3011]+[A 3110])
$$

$$
\begin{equation*}
[J P \phi]_{e}=[0] \tag{62}
\end{equation*}
$$

$$
\begin{align*}
& {[J \phi \phi]_{e}=\frac{1}{\Lambda_{e}}[\mathrm{~A} 211]} \\
& {[J \phi U]_{e}=a \Delta_{e}[A 200]} \\
& {[J \phi V]_{e}=[A 201]} \\
& {[J \phi P]_{e}=[0]} \tag{63}
\end{align*}
$$

In equations 60-63 all evaluations are made using $\{\cdot\}_{j+\rceil}^{p}$ unless otherwise noted. The parameter "a" in equations 62-63 denotes the fraction of $\{Q I\}_{j+1}^{p}$ used in the finite difference approximation for $\frac{d}{d}\{Q I\}$ at $x_{j+1}$.

## Numerical Results

Numerical experiments have been executed to evaluate the 2DPNS algorithm using various approximations to the Newton algorithm Jacobian, equations 60-63. The exact. construction is

$$
S_{e}\left[\begin{array}{cccc}
{[J U U]_{e}} & {[J U V]_{e}} & 0 & 0  \tag{64}\\
{[J V U]_{e}} & {[J V V]_{e}} & {[J V P]_{e}} & {[J V \phi]_{e}} \\
{[J P U]_{e}} & {[J P V]_{e}} & {[J P P]_{e}} & 0 \\
{[J \phi U]_{e}} & {[J \phi V]_{e}} & 0 & {[J \phi \phi]_{e}}
\end{array}\right]_{j+1}^{p}
$$

For reference, both the $2 D$ and $3 D$ algorithm constructions currently operational in the CMC:3DPNS code approximate equation 64 by its diagonal entries only. This decouples the dependent variable set solution in the nondiagonal terms premultiplied by $\Delta x$, eauations $60-63$, but retains the $\Delta x$-coupling through convection, pressure gradient and viscous-turbulent effects. Further, the original algorithm Poisson equation solutions are on $\{p\}$ and $\{\phi\}$, rather than $\{\delta P\}$ and $\{\delta \phi\}$, and both are computed using the most recent solutions $\{U\}_{j+1}^{p+1},\{V\}_{j+1}^{p+1}$, etc., rather than $\{Q I\}_{j+1}^{p}$, see equation 2 .

The 2 D algorithm construction for solution of $\{P\}$ and $\{\phi\}$ was rearranged and the code modified to permit PNS solutions using various approximations to [J]. The nearest equivalent to the original algorithm construction is,
$\left[\begin{array}{lll}{[J U U]} \\ & {[J V V]} \\ & {[J P P]} \\ & {[J \phi \phi]}\end{array}\right]_{j+1}^{p}\{\delta Q I\}_{j+1}^{p+1}=-\{F I\}_{j+1}^{p}$
where $\{F P\}$ and $\{F \phi\}$ are now evaluated using $\{Q I\}_{j+1}^{P}$. Defining the penalty variable as $\{S \phi\}$, see equations 56 and 59 , reproduced the original algorithm solution data to within negligible differences. The (finally) selected laminar flow standard test case used a geometrically nonuniform, unstretched grid of $M=56$ elements spanning $3 \delta_{0}$. The initialization of $\{U\}_{0}$ employed the Blasius solution, and the boundary layer thickness doubled over the integration length $\Delta x=4$, achieved in nominally 20 nonuniform integration steps $\Delta x$ at $\mathrm{Re}=3.2 \times 10^{6}$.

Table 2 summarizes data confirming the modified 2DPNS algorithm can generate an acceptably accurate solution on the $M=56$ mesh, with nodal coordinates as listed in column 1. Columns 2-4 compare the axial velocity profiles of the Blasius solution, the direct boundary layer (2DBL) solution using [JUU] and a direct trapezoidal rule integration of the continuity equation 14, and the basic 2DPNS algorithm. The matrix iteration convergence requirement was $|\delta U|<10^{-5}$, and peculiarities in starting the 2DPNS solution were exactly mimicked in generating the 2DBL solution. Hence, both numerical solutions are displaced axially from the Blasius solution by a negligible increment. The agreement between the 2DBL and 2DPNS solutions is excellent in both $u_{1}$ and in $u_{2}$, see columns 5-6 of Table 2. The transverse velocity distribution is the sensitive measure,since it ranges over five digits of significance over $\delta$ (see arrows) and is required to implicitly approximate a vanishing normal derivative at $y / \delta=0$.

With this confirmation, the principal interest is efficiency. Table 3 summarizes comparison data on convergence of the approximate Newton algorithm Jacobian constructions. All computations are done in single precision using a 32-bit word. Using the Blasius solution for $\{V(x, y)\}$ the $2 D B L$ data of the second column indicates use of [JUU] yields approximate quadratic convergence to $E(-7)$ for a scalar equation. Appending the direct continuity equation solution

for the $2 D B L\{V\}_{j+1}^{p+1}$, column 3, the convergence is quadratic only to $E(-4)$ for the two equation system. This decline in convergence rate for $|\delta U|_{\max }<10^{-4}$ characterizes all the 2DPNS algorithm solution constructions as well. The fourth column in Table 3 summarizes convergence of the original PNS algorithm (diagonal [JQQ], and solution for $\{P\}_{j+1}^{p+1}$ and $\{\phi\}_{p+1}^{p+1}$ using $\{Q I\}_{j+1}^{p+1}$, which is monotonic and approximately linear for $|\delta U|<10^{-4}$. The last column gives these data for the new algorithm construction, equation 64, with [JPU] and [J $\phi U$ ] omitted (since they cause instability and eventual divergence). Convergence is quadratic to $E(-4)$, and thereafter is nonmonotonic and sublinear (although these are extremum residuals occurring at different nodal coordinates at any iteration).

The current practice in CMC:3DPNS is $4-5$ iterations per step with convergence set at $|\delta Q|_{\max } \leq 10^{-4}$. Over this range the convergence character of the old diagonal [JQQ] construction and the coupled construction is nominally identical. Additional examinations were conducted to assess reasons for the poor convergence rate below $E(-4)$. Since the action of the penalty term is applied modulo a discrete (second-order) approximation to $\partial / \partial y$, the \{V\} solutions generated at ten iterations/step or more will eventually exhibit "wiggles." The current practice is to element average either \{ $\delta \mathrm{V}\}$ or $\{\mathrm{V}\}$ when this occurs. In Table 4, column 2 summarizes the standard test solution for $\{V\}$ using the original algorithm (for reference), column 3 contains the revised algorithm data using $\{V\}$ averaging, and column 4 contains the same algorithm solution without $\{\mathrm{V}\}$ or $\{\delta \mathrm{V}\}$ averaging. Close examination of the data in column 4 verifies periodic occurrences of local flat spots which will eventually grow into a $2 \Delta y$ wave. Since a $\{V\}$ and/or $\{\delta V\}$ average is tantamount to not using the coupled implicit solution vector \{ $\{Q \mathrm{I}\}$ as computed, this operation could contribute to poor convergence. A numerical test verified this to a limited extent, compare column 2 of Table 5 to column 5 of Table 3.

Alternatively, analysis determined that the "wiggles" in \{V\} can be traced back directly to $\{\phi\}$, hence $\{S \phi\}$, which if smoothed prior to use in equation 56 would not generate the discrete wave. The correct way to obliterate a $2 \Delta y$ wave is to use a Shuman-type digital filter, cf., [12, Ch. 4]. As an approximation, $\{S \phi\}_{j+1}^{p+1}$ was simply averaged. The accuracy of the resultant solution for $\{V\}$, column 5 in Table 4, is nominally identical to the \{V\}-averaged solution data, except directly adjacent to the wall where the averaging removed the critical sensitivity. This operation did improve the iteration convergence, column 3 in Table 5, mostly in returning it towards monotonicity below $|\delta U|_{\text {max }}<10^{-4}$.

The Newton Jacobian for these tests remained incomplete, since including either [JPU] or [J $\quad \mathrm{UU}$ ] would destabilize the algorithm. (Both these terms involve a discrete approximation to an axial derivative \{QI\}', see equations 62-63, to which the PNS penalty algorithm is quite sensitive.) The semi-implicit evaluation of $\{Q I\}^{\prime}$, of the form,

\end{equation*}
$$

is the standard procedure in CMC:3DPNS. With this simplification, the parameter "a" in equations 62 and 63 is zero. As a consequence, [J $\quad$ U] vanishes identically and [JPU] can be included without destabilization. Using $\{S \phi\}$ averaging, the accuracy of this algorithm form is nominally unchanged, see column 6 in Table 4. The resultant Newton Jacobian is exact and these results are a very modest improvement in monotonicity of convergence, see column 4 of Table 5. This convergence character is the closest to the original algorithm, recall column 4, Table 3. Of more significance, insertion of $\{S \phi\}$ averaging into the original algorithm construction significantly improves convergence, see column 5 of Table 5. This operation yields the PNS algorithm as efficient as the direct 2DBL solution, recall column 3 of Table 3.

A generalized coordinates form of the penalty finite element algorithm for the 3-dimensional parabolic Navier-Stokes equations for turbulent subsonic flows has been derived. This algorithm formulation requires only three distinct hypermatrices in its formulation and is applicable using any boundary fitted coordinate transformation procedure. The tensor matrix product approximation to the Jacobian of the Newton linear algebra matrix statement has been derived. The Newton algorithm has been restructured to replace the large sparse matrix solution procedure with a grid sweeping procedure using $\alpha$-block tridiagonal matrices where $\alpha$ equals the number of dependent variables.

The principal purpose of the reformulation is to improve solution economy. With the restructured Jacobian, solution economy is linearly dependent on the convergence (rate) of the Newton algorithm. A series of numerical experiments were performed to evaluate convergence as a function of Jacobian completeness and off-diagonal coupling. The results of these studies indicate that the favorable Newton quadratic convergence rate is maintained to a residual level of order $10^{-4}$. Thereafter the convergence rate uniformly decreases to linear for residual computations in the range $10^{-4}-10^{-5}$. Several modifications to the implicitness of the algorithm Jacobian and to the overall linear algebra statement were made and evaluated. Comparison to exact solutions indicates adequate accuracy is attainable for each of the modifications.

The results of this study provide required guidance on the appropriate form for the tensor product 3DPNS algorithm. The original form of the algorithm, employing a diagonal Jacobian, retarded evaluation of the Poisson equation solutions, in particular the $\phi$ solution, and $\{S \phi\}$ averaging for the penalty term yields the best Newton convergence performance and solution accuracy for the test case. The considerable effort in constructing and coding the off-diagonal Jacobian entries appears unrewarded, based upon these data, especially considering the added solution costs associated with a block versus scalar tridiagonal matrix. This indication gains considerable importance in the progression to turbulent and/or three-dimensional flows, wherein the Reynolds stress tensor will almost double the block size. Based on these data, it appears that the 3DPNS tensor product algorithm should employ a nominally diagonal tensor product Jacobian approximation for the initial-value variables, and should retard the Poisson equation solutions, which in themselves can use a scalar diagonal tensor product Jacobian approximation. The computation of Reynolds stresses would also employ a scalar diagonal form when using an algebraic model. This reconstruction of the 3DPNS algorithm would fit directly into the present CMC:3DPNS code. It is suggested that this should indeed by the next step.
