## SYMBOLS

A	coefficient in background noise curve fit
B	coefficient in background noise curve fit
$C_{LR/\sigma, R}$	isolated rotor lift coefficient, CLR/S, R, $L/\rho(\Omega R)^2 S$
$C_{P/\sigma}$	rotor power coefficient, CP/S, $P/\rho(\Omega R)^3 S$
c	speed of sound, m/sec
$\bar{c}$	blade chord at 75% radius, m
dB	sound pressure level, $20 \log(P_{rms}/P_{ref})$
dB <sub>B</sub>	background sound pressure level, $20 \log(P_{rms}/P_{ref})$
dB <sub>AC</sub>	A-weighted dB corrected for background noise
dB <sub>AU</sub>	A-weighted dB not corrected for background noise
dB <sub>BC</sub>	sound pressure level corrected for background noise
dB <sub>BU</sub>	sound pressure level not corrected for background noise
J THRUST	total thrust of J60 auxiliary propulsion engine, N
L	isolated rotor lift, N
M	wind tunnel Mach number, V/c
$M_{at}$	advancing tip Mach number, MAT, $(1 + \mu)M_{tip}$
$M_{tip}$	rotor rotational Mach number, MTIP, $\Omega R/c$
N	total number of blades
P	rotor power, W
P <sub>MAX</sub>	maximum pressure in time history sample, N/m <sup>2</sup>
P <sub>MIN</sub>	minimum pressure in time history sample, N/m <sup>2</sup>
P <sub>NdBC</sub>	perceived noise level corrected for background noise
P <sub>NdBU</sub>	perceived noise level not corrected for background noise
$P_{ref}$	reference pressure (0.00002 N/m <sup>2</sup> )
$P_{rms}$	root-mean-square sound pressure, N/m <sup>2</sup>
R	rotor radius, m

RPM	rotor rotational speed, rev/min
r	distance to microphone from midway between rotor hubs, m
S	reference area, $S = N\bar{C}R$ , $m^2$
v	wind tunnel speed, knots or m/sec
x	distance upstream from rotor center, m
y	distance left from rotor center looking upstream, m
z	distance up from midway between hubs, m
%RPM J1	auxiliary engine rotational speed expressed as percent of nominal value. RPM J1/16,000
%RPM J2	auxiliary engine rotational speed expressed as percent of nominal value. RPM J2/16,000
$\alpha$	angle of attack of rotor shaft, ALPHA, deg
$\Delta\theta$	upper rotor blade collective pitch minus lower rotor blade collective pitch, deg
$\mu$	rotor advance ratio, MU, V/ $\Omega R$
$\rho$	air density, kg/m <sup>3</sup>
$\sigma$	solidity, S/ $\pi R^2$
$\theta$	rotor blade collective pitch, deg
$\phi$	angle below rotor plane, $\tan^{-1}(-z/r)$ , deg
$\psi$	azimuth angle from downstream, $\tan^{-1}(-y/-x)$ , deg
$\Omega$	rotor rotational speed, rad/sec

## SUMMARY

Acoustic data were obtained during a full-scale test of the XH-59A Advancing Blade Concept Technology Demonstrator in the 40- by 80-Foot Wind Tunnel. The XH-59A is a research helicopter with two coaxial rotors and hingeless blades. Performance, vibration, and noise at various forward speeds, rotor lift coefficients and rotor shaft angles of attack were investigated. The noise data were acquired over an isolated rotor lift coefficient range of 0.024 to 0.162, an advance ratio range of 0.23 to 0.45 corresponding to tunnel wind speeds of 89 to 160 knots, and angles of attack from 0° to 10°. Acoustic data are presented for seven microphone locations for all run conditions where the model noise is above the background noise. Model test configuration and performance information are also listed. Acoustic waveforms, dBA, and 1/3-octave spectra as functions of operating condition for selected data points and microphones are presented. In general, the noise level is shown to increase with rotor lift coefficient except under certain operating conditions where significant impulsive blade/vortex interactions increase noise levels. The impulsivity appears to depend upon how the lift is distributed between the two rotors.

## INTRODUCTION

In the design and development of new helicopters, noise, as well as performance, handling qualities, and stability and control must be considered. This report describes the acoustic results from a recent full-scale test of an advanced technology rotorcraft. Under U.S. Army sponsorship, Sikorsky Aircraft built two XH-59A Advancing Blade Concept Technology Demonstrator helicopters that utilize two counter-rotating coaxial hingeless rotors to improve high-speed performance and increase cruise efficiency. On a conventional helicopter in forward flight, the rotor blades operate at a low lift coefficient on the advancing side because the rotor must produce no roll moment in level flight. The use of two counter-rotating rigid rotors allows each individual rotor to have a high lift coefficient on the advancing side while the aircraft has no total roll moment. The full-scale XH-59A Advancing Blade Concept (ABC) aircraft tested in the Ames 40- by 80-Foot Wind Tunnel is shown in figure 1. For additional information pertaining to the ABC concept, see references 1 through 3.

The ABC aircraft is significantly different from a conventional helicopter; therefore, one would expect the noise produced by this aircraft to differ from noise produced by a conventional helicopter. This aircraft has a slow rotational tip speed ( $M_{tip} = 0.52$  to 0.58) which may reduce the overall noise since all sources and convective amplification increase with increasing Mach number. Also, the high speed impulsive noise may be less than that of a conventional helicopter at a given forward speed because of the slower tip speed. However, high speed noise will still become a problem because this aircraft is designed to fly at faster speeds than a conventional rotorcraft. Also, under certain flight conditions, one would expect some impulsive blade slap due to the interaction of tip vortices from the upper rotor with the lower rotor.

This report presents the noise data of a full-scale ABC aircraft as measured in the Ames 40- by 80-Foot Wind Tunnel. Noise data were measured over an advance ratio range of 0.23 to 0.45 (89 knots to 160 knots) with the rotor on and from 60 to 180 knots with the rotor off. The rotor-on testing was conducted over an angle of attack range of 0° to 10°, and the auxiliary propulsion engines were operated at flight idle for all noise data runs.

## EXPERIMENT

The ABC aircraft (shown installed in the Ames 40- by 80-Foot Wind Tunnel in fig. 1) has two rotors, each containing three 5.5 m radius blades. General specifications for the ABC rotor system are listed in table 1. The midpoint between these two rotors was 1.5 m above the tunnel centerline. Viewed from above, the upper rotor of the model rotates in the counter-clockwise direction, and the lower rotor rotates in the clockwise direction. Collective, lateral cyclic, and longitudinal cyclic for each rotor were independently operated by six rotor controls, thereby allowing the rotors to independently apply trim forces and moments to the aircraft. The rotors were powered by two 552,000 W PT6T-3 turboshaft engines. Auxiliary propulsive force is provided by two nacelle-mounted J60-P3A turbojet engines which produce 13,300 N of thrust each. For a more detailed description of the aircraft, see Felker (ref. 3).

Performance, loads, and noise data for the full-scale ABC aircraft were measured in the Ames 40- by 80-Foot Wind Tunnel. Table 2 shows the flight conditions where data were taken. During testing, the rotor speed was adjusted to give the desired tip Mach number,  $M_{tip}$ , then the tunnel speed was adjusted to obtain the desired advance ratio,  $\mu$ . Noise data were then acquired for a matrix of isolated rotor lift coefficients,  $C_{LR/g,R}$ , and shaft angles,  $\alpha$ . The rotor-on testing was conducted over an isolated rotor lift coefficient range of 0.024 to 0.162 and an angle of attack range of 0° to 10°. The auxiliary propulsion engines were operated at flight idle for all noise data runs. For this test, the background wind tunnel noise was recorded at 60, 90, 120, and 180 knots with the model installed in the wind tunnel, the rotor blades off, the rotor head rotating, and the auxiliary engines operating at flight idle. A more detailed description of the test can be found in reference 3.

## DATA ACQUISITION AND REDUCTION

The acoustic data for this test were acquired using seven 1.3-cm condensor microphones equipped with nose cones to reduce wind-induced noise. Four of these microphones were located upstream of the model, and three microphones were located near the model. Three of the seven microphones were flush mounted on plates near the floor while the remaining four were mounted on stands at various heights below the midpoint between the two rotors. The microphone locations are given in table 3 and shown in figure 2; the coordinate system used is also shown. Signal conditioners were used to control the gain of the acoustic signal and to power the microphones. The acoustic signals were recorded on tape using a 14-track frequency-modulated (FM) tape recorder running at 15 ips. This gave a bandwidth of 10 kHz. All microphones were calibrated at the start and end of each day using a 124-dB, 250 Hz signal from a pistonphone. At each data point, a 50-sec sample of acoustic data was recorded for later analysis. In order to assure a maximum signal-to-noise ratio, the gain of the acoustic signal was adjusted in 10-dB intervals. A schematic of the data acquisition system is shown in figure 3.

Initially, the acoustic data were reduced and analyzed off-line on a minicomputer time series data system. Figure 4 shows a flow chart of the equipment used for data reduction. Data are digitized at a sample rate of 20 kHz while being played back through a low pass filter with a cutoff frequency of 10 kHz to prevent aliasing. From the digitized data, the minicomputer generated 1/3-octave spectra from 1-Hz spectra in the range of 10 to 200 Hz, and from 10-Hz spectra in the range of 250 Hz to 10 kHz. The minicomputer also computed dB, dBA, and PNdB from the 1/3-octave spectra and the first 10 blade passage harmonics from the 1-Hz, narrow-band spectra. The computed acoustic data were then transferred into a computer containing the data base with all of the measured test parameters. Background noise corrections, obtained with all the propulsion systems operating but rotor blades removed, were applied to the 1/3-octave spectra in the following manner. Background noise measurements were fitted to a linear regression of the form

$$dBB = A + B \cdot \log(V)$$

and then subtracted from the measured spectra on a power basis for each 1/3-octave,

$$dBC = 10 \log[10^{dB/10} - 10^{dBB/10}]$$

Graphs and tables were then constructed from this data base. The background noise levels used for corrections on microphones 1 through 7 are tabulated in appendix A. Appendix A also contains 1/3-octave plots of the averaged background noise measurements used at 89, 106, 142, and 160 knots, and plots of dBA as a function of velocity for each microphone. The effect of these corrections is to remove the jet noise as well as the background noise from the noise data.

## RESULTS AND DISCUSSION

Acoustic data for the XH-59A model are presented in appendix B. Performance and global acoustic measurements are listed for all of the microphones. The data are for rotor-on configurations at forward speeds of 89, 106, 142, and 160 knots and angles of attack from 0° to 10°.

Figures 5 through 10 show the general trends in the acoustic data with airspeed and shaft angle. Data from microphones 2, 4, and 7 are shown as a function of isolated rotor lift coefficient,  $C_{LR}/\sigma, R$ . Figures 5, 6, and 7 display the corrected dBA as a function of isolated rotor lift coefficient for tunnel wind speeds of 89, 106, and 142 knots, respectively. Data are grouped by shaft angle of attack (2.5°, 5.0°, and 7.5°) for each curve on each figure. Figures 8, 9, and 10 show the corrected dBA as a function of isolated rotor lift coefficient for angles of attack of 2.5°, 5.0°, and 7.5°, respectively. Data are grouped by tunnel wind speed (89, 106, and 142 knots) for each curve on each plot. In general, these figures (5 to 10) show an increase in noise level with increasing rotor lift coefficient. There are some exceptions to these trends and it is believed that this is due to impulsive blade/vortex interaction noise.

Blade/vortex interactions appear to depend on the control settings. Noise levels for a number of points in figure 10 are listed in table 4 with some control settings. Data are shown for shaft angle of attack of 7.5° and wind velocities of 89 and 106 knots. For each wind velocity, the data are listed in increasing order of rotor lift coefficient. The collective pitch,  $\theta$ , and the differential collective pitch,  $\Delta\theta$ , are included in the table. In the data at 106 knots, the noise levels

appear to depend on  $\Delta\theta$  as well as the rotor lift coefficient. Noise levels are higher for negative values of  $\Delta\theta$  than for positive values of  $\Delta\theta$  for some data with nearly identical rotor lift coefficients. Other data does not show this trend so no definitive conclusions can be made. Dependence of blade/vortex interaction upon lift distribution is a reasonable hypothesis; lift distribution effects the strength and location of the shed tip vortex and therefore would be expected to directly affect the blade/vortex interactions and impulsive noise.

Detailed acoustic data for selected data points are presented in appendix C. These data are for various wind speeds and angles of attack from microphones 2, 4, and 7. The tabulated data in appendix C shows 1/3-octave spectra, 1/3-octave spectra corrected for background noise, and the first 10 blade passage harmonic sound levels (dB).

Figures 11 through 17 show corrected 1/3-octave spectra as functions of isolated rotor lift coefficient. Each figure is for a specific tunnel wind speed, shaft angle of attack, and microphone. Data for microphones 2, 4, and 7 are shown for tunnel wind speeds of 89, 106, and 142 knots and for angles of attack of 2.5°, 5.0°, and 7.5°. Except for the frequency range 50 to 1600 Hz, the 1/3-octave spectra for all data are nearly the same. In this mid-frequency range, the sound pressure levels vary from point to point. The mid-frequency sound pressure levels follow the same trend seen in the dBA in figures 5 through 7. At 89 knots the mid-frequency noise levels increase as the rotor lift coefficient increases, and at the other wind tunnel speeds the noise levels are more sporadic. The curves also show that the energy in the high frequency range has been removed due to background noise corrections. This is because the noise of the auxiliary propulsive engines was included in the background noise measurements.

Figures 18 through 26 show typical time histories from the above 1/3-octave curves. Averaged time histories were obtained from the recorded microphone signals. A 1-per-revolution trigger signal was utilized to synchronize the microphone data, allowing constructive averaging of the coherent signal and destructive averaging of the random signal. Time histories are shown for data from microphone 4 located under the rotor. Each figure contains several time history plots for several isolated rotor lift coefficients at a fixed velocity and shaft angle. Velocities of 89, 106, and 142 knots and shaft angles of 2.5°, 5.0°, and 7.5° are used for the plots. The periodicity of the noise signals is very evident in these figures; all show a complicated time history with much high frequency harmonic noise. Some of the figures contain impulses from blade vortex interaction noise.

The time histories (figs. 18 to 20) for data taken at 89 knots show only a small amount of impulsive noise. The most impulsive data are for  $\alpha = 2.5^\circ$  and  $C_{LR}/c,R = 0.150$  which are also the data points with the highest noise level in figure 5b.

The time histories (figs. 21 to 23) for data taken at 106 knots show a mixture of impulsive and nonimpulsive noise. Some data are nonimpulsive and have low noise levels in figure 6b. Those points are identified with the following settings:  $\alpha = 5.0^\circ$  and  $C_{LR}/c,R = 0.114$ ;  $\alpha = 7.5^\circ$  and  $C_{LR}/c,R = 0.067, 0.116$ , and  $0.131$ . Some data are impulsive and have high noise levels in figure 6b. Those points can be identified with the following settings:  $\alpha = 7.5^\circ$  and  $C_{LR}/c,R = 0.093$  and  $0.106$ . The other time histories shown for 106 knots have moderate impulsive character and low to moderate noise levels in figure 6b.

The time histories (figs. 24 to 26) for some of the data taken at 142 knots show very little impulsive character except for the two points (fig. 24a  $\alpha = 7.5^\circ$ ,  $C_{LR}/\alpha, R = 0.079$ ; and fig. 26a  $\alpha = 7.5^\circ$ ,  $C_{LR}/\alpha, R = 0.090$ ) with slight impulsivity. The corresponding data in figure 7b have moderate noise levels with the two points mentioned above having higher noise levels than average.

In general, the time histories with a distinct impulsive nature correspond to data with high overall noise levels. The presence of this impulsive noise is not a simple function of the basic parameters of forward speed, isolated rotor lift coefficient, and angle of attack.

#### CONCLUDING REMARKS

Acoustic measurements of the XH-59A ABC Technology Demonstrator helicopter were obtained from a full-scale test in the NASA Ames 40- by 80-Foot Wind Tunnel. General noise measurements at all microphone locations and specific detailed noise measurements for three representative microphones are presented. From analysis of these test results, the following conclusions may be drawn:

1. Under certain operating conditions the rotor experienced significant blade/vortex interactions. How the lift was distributed between the upper and lower rotor may have a large influence on the impulsivity of the noise. Unfortunately, accurate measurements of all the control settings are not available; therefore, the effect of the controls on the noise cannot be quantified.
2. When impulses are not present, the noise level increases as the lift coefficient increases and as the angle of attack approaches  $0^\circ$  as in a typical rotor.

## APPENDIX A

The following tables and dB and dBA plots (figs. A1-A14) present the XH-59A ABC background noise data. The background noise data are presented in terms of 1/3-octave center frequencies, 1/3-octave spectra, and as a function of tunnel velocity (knots) for microphones 1 through 7.

Background noise data in terms of 1/3-octave center frequencies are presented first in tabular form for each microphone. One-third-octave spectra are presented next for tunnel wind speeds of 89, 106, 142, and 160 knots for each microphone. Lastly, the background noise at each microphone is presented as a function of tunnel velocity (knots).

## APPENDIX B

The following tables present acoustic and performance data for the XH-59A ABC model. Acoustic data are presented for microphones 1 through 7. The run/point number sequence used is based on tunnel velocity (knots), shaft angle of attack (ALPHA), and isolated rotor lift coefficient (CLR/S,R). The run/point numbers are ordered in terms of increasing isolated rotor lift coefficient at each tunnel velocity and shaft angle of attack.

## SYMBOLS

ALPHA	model pitch, positive up, deg
CLR/S,R	isolated rotor lift coefficient
CP/S	rotor power coefficient
DBAC	dBA corrected for background noise
DBAU	dBA not corrected for background noise
DBC	dB corrected for background noise
DBU	dB not corrected for background noise
J THRUST	total auxiliary engine thrust, N
MAT	advancing tip Mach number
MTIP	rotor tip Mach number
MTUN	tunnel Mach number
MU	advance ratio
PMAX	maximum pressure in time history sample, N/m <sup>2</sup>
PMIN	minimum pressure in time history sample, N/m <sup>2</sup>
PNDBC	PNdB corrected for background noise
PNDBU	PNdB not corrected for background noise
PT	point number
RPM	rotor rotational speed, rev/min
RUN	run number
VELOCITY	tunnel velocity, knots
VTIP	rotor tip velocity, m/sec

ZRPM J1 auxiliary engine rotational speed expressed as percent of nominal value,  
RPM J1/16,000

ZRPM J2 auxiliary engine rotational speed expressed as percent of nominal value,  
RPM J2/16,000

Acoustic data are presented in the following order:

The following tables present detailed XH-59A ABC acoustic data of selected points. Data are presented for microphones 2, 4, and 7. The run/point number sequence used is based on tunnel velocity (knots), shaft angle of attack (ALPHA), and isolated rotor lift coefficient (CLR/S,R). The run/point numbers are ordered in terms of increasing isolated rotor lift coefficient at each tunnel velocity and shaft angle of attack.

## SYMBOLS

ALPHA	model pitch, positive up, deg
CLR/S,R	isolated rotor lift coefficient
DBC	dB corrected for background noise
DBU	dB not corrected for background noise
MU	advance ratio
PT	point number
RUN	run number
VELOCITY	tunnel velocity, knots

Acoustic data for the selected points are presented in the following order:

RUN/PT	VELOCITY	ALPHA	CLR/S,R
