ACTIVE STABILIZATION OF A FLEXIBLE ANTENNA FEED TOWER

Arthur E. Bryson, Jr.
Stanford University
Stanford, California

ABSTRACT

Active stabilization logic is synthesized to hold a feed at the focus of a spacecraft antenna dish. The feed support structure is modeled as a tetrahedron made up of flexible bars and connected to the dish by six short legs containing force actuators. Using the symmetry of the structure, the model can be decomposed into four uncoupled subsystems: (1) pitch/forward motions with four degrees of freedom (DOF) and two controls, (2) roll/lateral motions with four DOF and two controls, (3) vertical motions with three DOF and one control, and (4) yaw motion with one DOF and one control. This greatly simplifies the synthesis of control logic.

INTRODUCTION

A spacecraft consists of a massive central body with a large antenna dish at one end; the feed for this antenna is mounted to the dish with a flexible support structure consisting of twelve bar-like members. (See fig. 1.) Six of the bars form a regular tetrahedron, with the feed at the apex. Two legs connect each of the three joints at the base of the tetrahedron to the antenna-dish/spacecraft, which we shall approximate as an inertial frame of reference due to its large mass. The mass of the structure will be lumped at the four joints of the tetrahedron, and the bars will be approximated as springs with axial deformation only.

The design objective is to control the four lowest frequency vibration modes that involve lateral motions of the feed so that they are at least 10 percent critically damped.

SEPARATION INTO SYMMETRIC AND ANTISYMMETRIC MOTIONS

Motions symmetric with respect to y-z plane involve seven degrees of freedom:

$$y_1, \; z_1, \; x_2 = -x_3, \quad y_2 = y_3, \quad z_2 = z_3, \; y_4, \; z_4$$

Motions antisymmetric with respect to y-z plane involve five degrees of freedom:

$$x_1, \; x_2 = x_3, \quad y_2 = -y_3, \quad z_2 = z_3, \; x_4$$

Three of the symmetric modes involve only vertical (z_1) motions of the apex, and one antisymmetric mode is symmetric about the z axis (a yaw mode), producing zero motion of the apex. The remaining eight modes consist of two sets of four modes that have identical frequencies, but one set involves symmetric motions and the other set involves antisymmetric motions.

The actuator forces can be arranged into six sets, one of which controls only the yaw mode, another that controls only z_1 motions, and two sets of two that control the remaining symmetric and antisymmetric modes, respectively. Thus the stabilization problem may be reduced to two almost identical problems of controlling four modes with two controls.

EQUATIONS OF MOTION

Let $\vec{r}_i$ be displacement vector of ith joint, $\vec{m}_{ij}$ be position vector from ith joint to jth joint, and k_1, k_2, k_ℓ be equal to EA/mL^3 for base members, vertical members, and legs, respectively. Then

$$\ddot{\vec{r}}_1 = -k_2\vec{m}_{1,2}\vec{m}_{1,2}\cdot(\vec{r}_1 - \vec{r}_2) - k_2\vec{m}_{1,3}\vec{m}_{1,3}\cdot(\vec{r}_1 - \vec{r}_3) - k_2\vec{m}_{1,4}\vec{m}_{1,4}\cdot(\vec{r}_1 - \vec{r}_4)$$

$$\ddot{\vec{r}}_2 = -k_2\vec{m}_{1,2}\vec{m}_{1,2}\cdot(\vec{r}_2 - \vec{r}_1) - k_1\vec{m}_{2,3}\vec{m}_{2,3}\cdot(\vec{r}_2 - \vec{r}_3) - k_1\vec{m}_{2,4}\vec{m}_{2,4}\cdot(\vec{r}_2 - \vec{r}_4)$$

$$- k_\ell\vec{m}_{2,5}\vec{m}_{2,5}\cdot\vec{r}_2 - k_\ell\vec{m}_{2,6}\vec{m}_{2,6}\cdot\vec{r}_2 + \vec{m}_{2,5}f_{2,5} + \vec{m}_{2,6}f_{2,6}$$

$$\ddot{\vec{r}}_3 = -k_2\vec{m}_{1,3}\vec{m}_{1,3}\cdot(\vec{r}_3 - \vec{r}_1) - k_1\vec{m}_{2,3}\vec{m}_{2,3}\cdot(\vec{r}_3 - \vec{r}_2) - k_1\vec{m}_{3,4}\vec{m}_{3,4}\cdot(\vec{r}_3 - \vec{r}_4)$$

$$- k_\ell\vec{m}_{3,7}\vec{m}_{3,7}\cdot\vec{r}_{3,7} - k_\ell\vec{m}_{3,8}\vec{m}_{3,8}\cdot\vec{r}_3 + \vec{m}_{3,7}f_{3,7} + \vec{m}_{3,8}f_{3,8}$$

$$\ddot{\vec{r}}_4 = -k_2\vec{m}_{1,4}\vec{m}_{1,4}\cdot(\vec{r}_4 - \vec{r}_1) - k_1\vec{m}_{2,4}\vec{m}_{2,4}\cdot(\vec{r}_4 - \vec{r}_2) - k_1\vec{m}_{3,4}\vec{m}_{3,4}\cdot(\vec{r}_4 - \vec{r}_3)$$

$$- k_\ell\vec{m}_{4,9}\vec{m}_{4,9}\cdot\vec{r}_4 - k_\ell\vec{m}_{4,10}\vec{m}_{4,10}\cdot\vec{r}_4 + \vec{m}_{4,9}f_{4,9} + \vec{m}_{4,10}f_{4,10}$$

For nominal configuration,

$$k_1 = \frac{(1)(1000)}{(2)(10)^3} = 0.5$$

$$k_2 = \frac{(1)(100)}{(2)(10)^3} = 0.05$$

$$k_\ell = \frac{(1)(100)}{(2)(2\sqrt{2})^3} = 2.2097$$

COMPUTER CODE "TETRA"

Calculates 12×12 K matrix, where

$$\frac{d^2}{dt^2}\begin{bmatrix} r_1 \\ \cdots \\ r_2 \\ \cdots \\ r_3 \\ \cdots \\ r_4 \end{bmatrix} = -K\begin{bmatrix} r_1 \\ \cdots \\ r_2 \\ \cdots \\ r_3 \\ \cdots \\ r_4 \end{bmatrix} + Gf$$

Calculates 7×7 K_S matrix and 5×5 K_A matrix, where

$$\ddot{d}_S = -K_S d_S + G_S f_S$$

$$\ddot{d}_A = -K_A d_A + G_A f_A$$

$$d_S \triangleq \left[y_1,\ z_1,\ \frac{x_2 - x_3}{2},\ \frac{y_2 + y_3}{2},\ \frac{z_2 + z_3}{2},\ y_4,\ z_4\right]^T$$

$$d_A \triangleq \left[x_1,\ \frac{x_2 + x_3}{2},\ \frac{y_2 - y_3}{2},\ \frac{z_2 - z_3}{2},\ x_4\right]^T$$

$$f_S \triangleq \left[\frac{H_2 - H_3}{2},\ \frac{V_2 + V_3}{2},\ V_4\right]^T$$

$$f_A \triangleq \left[\frac{H_2 + H_3}{2},\ \frac{V_2 - V_3}{2},\ H_4\right]^T$$

Note actuator forces resolved into vertical and horizontal components (V_i, H_i) at joints i = 2,3,4, which makes the determination of G_S,G_A quite simple.

EQUATIONS OF MOTION IN MODAL FORM

Using computer code "MODALSYS", the symmetric and antisymmetric equations of motion were put into modal form. Sketches of these mode shapes are given in figures 2 through 4. Only four modes involve fore-aft (y_1) motions of the apex (fig. 2). Another four modes involve only lateral (x_1) motions of the apex (fig. 3). Another three modes involve only vertical (z_1) motions of the apex (fig. 4). One mode involves no motion of the apex (fig. 5).

SEPARATION INTO FOUR SUBSYSTEMS

Only two linear combinations of actuator forces enter into the y_1 apex motions. (See first example of modal controllability matrix.) We shall call them f_{pitch} and f_{fwd}. Two different linear combinations of actuator forces enter into the x_1 apex motions. (See second example of modal controllability matrix.) They will be referred to as f_{roll} and f_{flat}. One different linear combination of actuator forces enters into the z_1 apex motions. It is called f_{vert}. One different linear combination of actuator forces involves no apex motion, and is called f_{yaw}. The equations of motion for these four subsystems are given elsewhere in this paper.
