Earth Resources A Continuing Bibliography with Indexes NASA SP-7041(35) October 1982

National Aeronautics and Space Administration

N83-16805 (NASA-SP-7041(35)) EARTH RESOURCES: Α CONTINUING BIBLIOGRAPHY WITH INDEXES, ISSUE 35 (National Aeronautics and Space Unclas Administration) 160 p HC A08 CSCL 05B 02532 00/43 Earth Resource Earth Resources Resources **Resources Earth** irces Lar **Leso**

ACCESSION NUMBER RANGES

Accession numbers cited in this Supplement fall within the following ranges.

STAR (N-10000 Series)	N82-22141 - N82-28242
IAA (A-10000 Series)	A82-28539 - A82-38102

1

This bibliography was prepared by the NASA Scientific and Technical Information Facility operated for the National Aeronautics and Space Administration by PRC Government Information Systems.

EARTH RESOURCES

A CONTINUING BIBLIOGRAPHY WITH INDEXES

Issue 35

A selection of annotated references to unclassified reports and journal articles that were introduced into the NASA scientific and technical information system and announced between July 1 and September 30, 1982 in

~

- Scientific and Technical Aerospace Reports (STAR)
- International Aerospace Abstracts (IAA).

This supplement is available as NTISUB/038/093 from the National Technical Information Service (NTIS), Springfield, Virginia 22161 at the price of \$10 50 domestic; \$21.50 foreign for standing orders. Please note. Standing orders are subscriptions which do not terminate at the end of a year, as do regular subscriptions, but continue indefinitely unless specifically terminated by the subscriber.

...

INTRODUCTION

The technical literature described in this continuing bibliography may be helpful to researchers in numerous disciplines such as agriculture and forestry, geography and cartography, geology and mining, oceanography and fishing, environmental control, and many others. Until recently it was impossible for anyone to examine more than a minute fraction of the Earth's surface continuously. Now vast areas can be observed synoptically, and changes noted in both the Earth's lands and waters, by sensing instrumention on orbiting spacecraft or on aircraft.

This literature survey lists 587 reports, articles, and other documents announced between July 1 and September 30, 1982 in *Scientific and Technical Aerospace Reports (STAR)*, and *International Aerospace Abstracts (IAA)*.

The coverage includes documents related to the identification and evaluation by means of sensors in spacecraft and aircraft of vegetation, minerals, and other natural resources, and the techniques and potentialities of surveying and keeping up-to-date inventories of such riches. It encompasses studies of such natural phenomena as earthquakes, volcanoes, ocean currents, and magnetic fields; and such cultural phenomena as cities, transportation networks, and irrigation systems. Descriptions of the components and use of remote sensing and geophysical instrumentation, their subsystems, observational procedures, signature and analyses and interpretive techniques for gathering data are also included. All reports generated under NASA's Earth Resources Survey Program for the time period covered in this bibliography will also be included. The bibliography does not contain citations to documents dealing mainly with satellites or satellite equipment used in navigation or communication systems, nor with instrumentation not used aboard aerospace vehicles.

The selected items are grouped in nine categories. These are listed in the Table of Contents with notes regarding the scope of each category. These categories were especially chosen for this publication, and differ from those found in *STAR* and *IAA*.

Each entry consists of a standard bibliographic citation accompanied by an abstract. The citations and abstracts are reproduced exactly as they appeared originally in *STAR*, or *IAA*, including the original accession numbers from the respective announcement journals. This procedure, which saves time and money, accounts for the variation in citation appearance.

Under each of the nine categories, the entries are presented in one of two groups that appear in the following order:

IAA entries identified by accession number series A82-10,000 in ascending accession number order;

STAR entries identified by accession number series N82-10,000 in ascending accession number order.

After the abstract section, there are six indexes:

subject, personal author, corporate source, contract number, report/accession number, and accession number.

AVAILABILITY OF CITED PUBLICATIONS

IAA ENTRIES (A82-10000 Series)

All publications abstracted in this Section are available from the Technical Information Service, American Institute of Aeronautics and Astronautics, Inc (AIAA), as follows Paper copies of accessions are available at \$8.00 per document Microfiche⁽¹⁾ of documents announced in *IAA* are available at the rate of \$4.00 per microfiche on demand, and at the rate of \$1.35 per microfiche for standing orders for all *IAA* microfiche

Minimum air-mail postage to foreign countries is \$2.50 and all foreign orders are shipped on payment of pro-forma invoices

All inquiries and requests should be addressed to AIAA Technical Information Service Please refer to the accession number when requesting publications

STAR ENTRIES (N82-10000 Series)

١,

One or more sources from which a document announced in *STAR* is available to the public is ordinarily given on the last line of the citation. The most commonly indicated sources and their acronyms or abbreviations are listed below. If the publication is available from a source other than those listed, the publisher and his address will be displayed on the availability line or in combination with the corporate source line

Avail: NTIS. Sold by the National Technical Information Service Prices for hard copy (HC) and microfiche (MF) are indicated by a price code preceded by the letters HC or MF in the *STAR* citation Current values for the price codes are given in the tables on page vii.

Documents on microfiche are designated by a pound sign (#) following the accession number. The pound sign is used without regard to the source or quality of the microfiche.

Initially distributed microfiche under the NTIS SRIM (Selected Research in Microfiche) is available at greatly reduced unit prices. For this service and for information concerning subscription to NASA printed reports, consult the NTIS Subscription. Section, Springfield, Va 22161

NOTE ON ORDERING DOCUMENTS: When ordering NASA publications (those followed by the * symbol), use the N accession number NASA patent applications (only the specifications are offered) should be ordered by the US-Patent-Appl-SN number Non-NASA publications (no asterisk) should be ordered by the AD, PB, or other *report* number shown on the last line of the citation, not by the N accession number. It is also advisable to cite the title and other bibliographic identification

- Avail SOD (or GPO) Sold by the Superintendent of Documents, U.S. Government Printing Office, in hard copy The current price and order number are given following the availability line. (NTIS will fill microfiche requests, at the standard \$4.00 price, for those documents identified by a # symbol)
- Avail NASA Public Document Rooms Documents so indicated may be examined at or purchased from the National Aeronautics and Space Administration, Public Document Room (Room 126), 600 Independence Ave., S.W, Washington, D.C. 20546, or public document rooms located at each of the NASA research centers, the NASA Space Technology Laboratories, and the NASA Pasadena Office at the Jet Propulsion Laboratory

⁽¹⁾ A microfiche is a transparent sheet of film 105 by 148 mm in size containing as many as 60 to 98 pages of information reduced to micro images (not to exceed 26.1 reduction)

- Avail. DOE Depository Libraries. Organizations in U.S. cities and abroad that maintain collections of Department of Energy reports, usually in microfiche form, are listed in *Energy Research Abstracts*. Services available from the DOE and its depositories are described in a booklet, *DOE Technical Information Center Its Functions and Services* (TID-4660), which may be obtained without charge from the DOE Technical Information Center.
- Avail: Univ. Microfilms Documents so indicated are dissertations selected from *Dissertation Abstracts* and are sold by University Microfilms as xerographic copy (HC) and microfilm All requests should cite the author and the Order Number as they appear in the citation.
- Avail: USGS. Originals of many reports from the U.S. Geological Survey, which may contain color illustrations, or otherwise may not have the quality of illustrations preserved in the microfiche or facsimile reproduction, may be examined by the public at the libraries of the USGS field offices whose addresses are listed in this introduction. The libraries may be queried concerning the availability of specific documents and the possible utilization of local copying services, such as color reproduction.
- Avail: HMSO. Publications of Her Majesty's Stationery Office are sold in the U.S. by Pendragon House, Inc (PHI), Redwood City, California. The U.S. price (including a service and mailing charge) is given, or a conversion table may be obtained from PHI.
- Avail: BLL (formerly NLL): British Library Lending Division, Boston Spa, Wetherby, Yorkshire, England. Photocopies available from this organization at the price shown (If none is given, inquiry should be addressed to the BLL.)
- Avail: Fachinformationszentrum, Karlsruhe. Sold by the Fachinformationszentrum Energie, Physik, Mathematik GMBH, Eggenstein Leopoldshafen, Federal Republic of Germany, at the price shown in deutschmarks (DM).
- Avail: Issuing Activity, or Corporate Author, or no indication of availability Inquiries as to the availability of these documents should be addressed to the organization shown in the citation as the corporate author of the document
- Avail U.S. Patent and Trademark Office. Sold by Commissioner of Patents and Trademarks, U.S. Patent and Trademark Office, at the standard price of 50 cents each, postage free.
- Other availabilities: If the publication is available from a source other than the above, the publisher and his address will be displayed entirely on the availability line or in combination with the corporate author line.

A82-22539

A REPORT ON THE 'COSMIC RAY PROPAGATION PROBLEM'

P. S. FREIER (Minnesota, University, Minneapolis, MN) International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 182-185 refs

Data on abundances of elements are now of such quality, that the major source of discrepancies in cosmic ray propagation results is believed to be due to a difference in the propagation programs being used by different groups Nine groups were therefore asked to use a standardized source, E equals 23 GeV/n with no energy loss, and propagate it through a 5 g/sq cm exponential path length of hydrogen, using their values of the Silverberg and Tsao cross sections at 2.3 GeV/n (1973, 1977, 1979). Results indicate significant discrepancies arising from propagation, demonstrating the differences that can result when different physical conditions are assumed. JE.

A82-22541* Chicago Univ., III.

THE QUESTION OF SHORT PATHLENGTHS IN INTERSTELLAR PROPAGATION

M GARCIA-MUNOZ, T. G. GUZIK, J. A SIMPSON, and J. P. WEFEL (Chicago, University, Chicago, IL) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 192-195. refs

(Contract NAS5-25731; NGL-14-001-006)

Interstellar propagation calculations for cosmic rays, He-4 -Ni-64, are compared with currently available abundance ratios for B/C and sub-Fe/Fe The calculations show that an exponential pathlength distribution (leaky box model) cannot reproduce both secondary to primary ratios in the interval 0.5-1 GeV/n unless some values of the propagation parameters are modified. The calculated ratios are shown to be particularly sensitive to the adopted cross sections, the presence of the sub-Fe elements in the source regions, the shape of the source energy spectrum, and ionization energy loss. (Author)

A82-22542* National Aeronautics and Space Administration Goddard Space Flight Center, Greenbelt, Md. THE COSMIC RAY POSITRON SPECTRUM

R. J. PROTHEROE (NASA, Goddard Space Flight Center, Laboratory for High Energy Astrophysics, Greenbelt, MD) In International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 198-201 refs

A calculation is made of the flux of secondary positrons expected above 100 MeV for various disk-halo diffusion models,

which are consistent with the observed grammage and Be-10 abundance. It is found that models which give a high surviving fraction of Be-10 (about 0.3) give a secondary positron spectrum which is consistent with the observations, while a model predicting a low Be-10 abundance (about 0.1 surviving) gives a poorer fit at high energies hinting at the presence of a primary positron component. Implications of these results are discussed. (Author)

A82-22543

THE ELECTRON AND POSITRON SPECTRA IN PRIMARY COSMIC RAYS

L C TAN and L. K. NG (University of Hong Kong, Hong Kong) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 202-205. refs

It is contended that variations in the results of various authors' positron calculations derive mainly from differences between the local interstellar electron spectrum and those derived from radio data. It is found that, among the spectra derived from radio data, that of Rockstroh and Webber (1978) is the most consistent with the description using the usual 'leaky box' model. In addition, it is shown that the electron injection spectrum with a single power law cannot satisfactorily explain the primary electron spectrum. Analysis also shows that the leaky box model is able to account for the mean behavior of interstellar positrons and electrons in a cosmic ray containment volume whose galactic scale height and width around the earth are, respectively, 0 5-1 kpc and 2-3 kpc CR

A82-22544

COMPARISON OF THE MEASURED ANTIPROTON FLUX WITH THAT PREDICTED BY THE 'LEAKY BOX' MODEL

L C TAN and L. K. NG (University of Hong Kong, Hong Kong) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 210-213 refs

A82-22552

STEADY-STATE COSMIC RAY ELECTRON SPECTRUM UNDER DIFFUSION, CONVECTION, ADIABATIC DECELERATION AND SYNCHROTRON LOSSES

LERCHE (Chicago, University, Chicago, IL) and R SCHLICKE6SER (Max-Planck-Institut fur Radioastronomie, Bonn, West Germany) In International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 244-247 Deutsche Forschungsgemeinschaft refs

(Contract DFG-SCHL-201/1)

MASS PER CHARGE RATIO IN HOT PLASMAS AND COSMIC RAY SOURCE COMPOSITION

C J CESARSKY, R ROTHENFLUG, and M CASSE (Commissariat a l'Energie Atomique, Centre d'Etudes Nucleaires de Saclay, Gif-sur-Yvette, Essonne, France) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 269-272. refs

Some models of shock acceleration of cosmic rays assume that particles are injected out of the thermal plasma behind the shock and are selected according to their effective charge (Eichler, 1979; Ellison et al., 1981). The pattern of compositions that could emerge from such a selection starting from plasmas in ionization equilibrium at various temperatures greater than or equal to 100,000 K and containing no grains is considered. It is found that, in the case of steady state ionization equilibrium and of time-dependent cooling of a hot plasma, which are possible descriptions of the hot ISM and of the halo gas, it is not possible to reproduce the observed cosmic ray composition with this simple scheme

(Author)

A82-22559

PHYSICAL STATE OF THE BIRTH PLACE OF COSMIC RAYS AND ITS IMPLICATION TO THE ACCELERATION PROCESSES K SAKURAI (Kanagawa University, Yokohama, Japan) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 277-280 refs

To explain the observed chemical composition of galactic cosmic rays at their sources, it is suggested that this composition is the result of an acceleration mechanism, possibly related to the charge states of particles ambient in the source regions. Since it is likely that most of the particles are partially ionized in these regions, the ambient temperature there will be less than 100,000 K before the start of acceleration. C.R

A82-22560

ON VOLATILITY, FIRST IONIZATION POTENTIAL, AND S- AND R-PROCESSES

J. P MEYER (Commissariat a l'Energie Atomique, Centre d'Etudes Nucleaires de Saclay, Gif-sur-Yvette, Essonne, France) In International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 281-284 refs

The possibility of a correlation between the first ionization potential and volatility (in that elements of low potential tend to be refractory and those of high potential volatile) is considered. It is noted that the apparent correlation between galactic cosmic ray source (GCRS) elemental abundances and the first ionization potential may in fact be based on volatility. Attention is given here to compositional clues which may determine whether volatility or the first ionization potential is the relevant parameter. The correlation between the first ionization potential and volatility is examined, and those elements which do not fit into the correlation are isolated Attention is also given to possible ambiguities in interpreting the charge spectrum beyond Ni that derive from coincidences between regions of change in the first ionization (and volatility) and the s- and r-process peaks.

A82-22561

INTERSTELLAR GRAINS AS SEEDS FOR GALACTIC COSMIC RAYS

J.-P. BIBRING (CNRS, Centre de Spectrometrie Nucleaire et de Spectrometrie de Masse, Orsay, Essonne, France) and C. J CESARSKY (Commissariat a l'Energie Atomique, Centre d'Etudes Nucleaires de Saclay, Gif-sur-Yvette, Essonne, France) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 289-291. refs

A82-22563

ORIGIN OF GALACTIC COSMIC RAYS FROM NE ISOTOPIC COMPOSITION

J. AUDOUZE (CNRS, Institut d'Astrophysique, Paris; CNRS, Centre de Spectrometrie Nucleaire et de Spectrometrie de Masse, Orsay, Essonne, France), M. CASSE, J. A PAUL (Commissariat a l'Energie Atomique, Centre d'Etudes Nucleaires de Saclay, Gif-sur-Yvette, Essonne, France), J. P. CHIEZE (CNRS, Institut d'Astrophysique, Paris; Centre d'Etudes Nucleaires de Bruyere-le-Chatel, Montrouge, Hauts-de-Seine, France), and G. MALINIE (CNRS, Institut d'Astrophysique, Paris, France). In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 296-298. refs

The possibility that a cosmic ray composition reflecting that of the interstellar medium may account for the observed enhancement of the cosmic ray Ne-22/Ne-20 abundance ratio with respect to the solar value is examined Processes leading to the observed solar system abundances of Ne-22 are discussed, and it is suggested that explosive hydrogen burning might be a significant source, since secondary production of this isotope as a by-product of the CNO cycle in intermediate and massive stars is incapable of accounting for the present abundance Calculations are presented which show that neither Ne-22 enrichment of the interstellar medium by low-mass stars after the birth of the sun nor a cosmic ray origin in the inner galaxy account for the observed cosmic ray enrichment. It is thus concluded that Ne-22 cannot have been significantly enriched in the interstellar medium during the last 4.6 billion years, and thus cosmic rays are accelerated in the vicinity of Ne-22 sources. A.L.W.

A82-22564

EVIDENCE FOR THE STOCHASTIC ACCELERATION OF COSMIC RAYS IN SUPERNOVA REMNANTS

T. W. HARQUIST (University College, London, England) and G. E. MORFILL (Max-Planck-Institut fuer Kernphysik, Heidelberg, West Germany) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissanat a l'Energie Atomique, 1981, p 300-302 refs

Ionization rates in several locations in an expanding shell, probably formed by the passage of a shock driven by the expansion of an old supernova remnant in the Per OB2 association, have been derived from molecular observations. The production of 1-2 MeV cosmic rays by the second order Fermi mechanism in the ionized regions of the remnant would explain these and a number of other molecular observations. (Author)

A82-22565 THE GALACTIC ORIGIN OF COSMIC RAYS. I

S. A. COLGATE (Los Alamos National Laboratory, Los Alamos, New Mexico Institute of Mining and Technology, Socorro, NM) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 303-306. refs

(CONF-810711-1; LA-UR-81-965)

The theoretical basis for the supernova envelope shock origin of cosmic rays is reviewed. The theoretical explanation of the SN Type I light curve requires the ejection of a relativistic mass fraction. The criterion of the adiabatic deceleration by Alfven wave trapping neither applies in theory, when beta is greater than 1, or practice, as in the Starfish high-altitude nuclear explosion experiment. Arguments of delayed acceleration due to K-capture are not applicable to SN ejecta because a period of prompt recombination exists before subsequent stripping in propagation. (Author)

ORIGIN OF COSMIC RAYS IN GALACTIC CENTRE SOURCES

S S. SAID, A W. WOLFENDALE (Durham, University, Durham, England), M GILER (Lodz, Uniwersytet, Lodz, Poland), and J. WDOWCZYK (Instytut Badan Jadrowych, Lodz, Poland) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 344-347. refs

A model is proposed which attributes the origin of cosmic rays to rare explosive events in galactic nuclei. In accordance with the model, the individual explosions are separated by times of the order of 100 million years, and the duration of each explosion is much shorter than the period of separation Particles produced with a power-law spectrum would propagate by diffusion throughout the Galaxy, and in its simplest form, there would be simple three-dimensional diffusion with a diffusion coefficient independent of position. The proposed model could provide an explanation for the very low electron-to-proton ratio (about 3 percent at 1 GeV) of cosmic radiation at the earth.

A82-22572

ACCELERATION PROCESSES NEAR MASSIVE BLACK HOLES

M KAFATOS (George Mason University, Fairfax, VA), R SILBERBERG, and M. M. SHAPIRO (U.S. Navy, Naval Research Laboratory, Washington, DC) In International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 348-351. refs

Ultra-massive accreting black holes in the nuclei of active galaxies have been proposed as the central sources of energy emission, especially of the nonthermal kind Accretion disks around massive black holes in the centers of active galactic nuclei are shown to be likely sites of particle acceleration Electrons can be accelerated to relativistic energies by electromagnetic processes as well as purely gravitational processes (e.g., Penrose pair production). Protons are also accelerated to very high energies by processes such as (1) Fermi acceleration, (2) betatron acceleration, (3) shock wave acceleration, and (4) in beams via the electromagnetic dynamo process The stochastic Fermi process acting over a period of only about a day in the ergosphere suffices for efficient acceleration of protons, even to high energies.

INTERPLANETARY PARTICLE OBSERVATIONS ASSOCIATED WITH SOLAR FLARE GAMMA-RAY LINE EMISSION

T. T. VON ROSENVINGE, R. RAMATY, and V. REAMES (NASA, Goddard Space Flight Center, Laboratory for High Energy Astrophysics, Greenbelt, MD) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 28-31 refs

Observations of particle emissions during three solar flares which were observed to emit 2.22 MeV gamma rays as recorded by the Solar Maximum Mission are discussed. The 2.22 MeV line is produced by neutron capture by hydrogen, and additional attention is given to a 4.4 MeV emission line of June 7, 1980, with estimates made of the particle density 1 AU from the sun assuming a good magnetic connection between the earth and the sun. The measurements were made from the ISEE-3 and HELIOS-1 spacecraft. The connectedness of the earth and the sun in a magnetic field leads to conclusions that few particles actually escaped into interplanetary space M.S.K.

COMPUTER SIMULATION OF THE TIME DEPENDENCE OF THE PHOTON ENERGY SPECTRA PRODUCED IN PROTON AND ELECTRON BREMSTRAHLUNG

S. R. KELNER, IU. D KOTOV, A. S ROSHAL, and V. N. RUSSKIKH (Moskovskii Inzherno-Fizicheskii Institut, Moscow, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 41-44 refs

An analytic model of the time dependence of the photon generation spectra resulting from proton and electron bremsstrahlung in matter is presented. The lifetimes of the protons and electrons with the same Lorentz factor are shown to differ by a factor of at least three, which implies that the time dependence of photon energy spectra resulting from pulse beam injection of accelerated particles into a generation region depends on the types of particles accelerated. Basic equations are formulated for the evolution of the proton distribution function in matter, with consideration given to path lengths which remain or pass from the matter The proton energy spectrum is then defined and the generation function for the production of gamma rays in a target block is derived, taking into account the density of the target Similar calculations for electrons showed that with time the energy spectra becames harder for electrons. POSSIBLE EVIDENCE FOR ATTENUATION OF AN MHD SHOCK BY A MAGNETIC NEUTRAL SHEET IN THE SOLAR CORONA D. J. MULLAN (Franklin Institute, Bartol Research Foundation, Newark, DE) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 51-54. refs

(Contract NSF ATM-78-20936-01)

The possibility that H-alpha filaments in the solar chromosphere are markers beneath regions where coronal shocks experience severe attenuation, and are thus the areas where particles can be ejected from the corona, is examined from data from flares of Aug 4, 1972 and Nov. 9, 1979 Both flares produced gamma rays with 2.2 MeV energy, and data exists for the energetic protons received at earth stations. The efficiency of transport was high for the August event and two magnitudes lower for the November event. H-alpha filtergrams of the two flares show that in the second flare the shock propagation crossed two or three filaments lying in its path. The low efficiency of particle transport is taken to indicate a degraded shock in the region above the filaments, indicating that the particles needed a different route to escape.

A82-22591* Chicago Univ., III THE RELATION OF TYPE II RADIO BURSTS TO SOLAR ENERGETIC PARTICLES OBSERVED AT EARTH

P EVENSON, P. MEYER (Chicago, University, Chicago, IL), and S. YANAGITA In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 59-62. refs (Contract NAS5-20674)

Observations of particle events associated with type II radio bursts as recorded on the ISEE-3 spacecraft are reported. Data on burst events following flares of Sept 23,1978 and Aug. 18, 1979 yield time histories of the particle fluxes, which exceeded 25 MeV energy. The profiles of the Category-1 type II bursts display a continuous release of particles, which was concluded by no decrease in the fluxes until after the passage of the shock. The continuous nature of the recorded events suggests that the secondary acceleration process associated with the type II bursts is maintained as the flare shock propagates through interplanetary space, and may be the source of the energetic particles which propagate with the shock M.S.K. **A82-22592*** National Aeronautics and Space Administration. A SURVEY OF SOLAR PROTONS AND ALPHA DIFFERENTIAL SPECTRA BETWEEN 1 AND GREATER THAN 400 MEV/NUCLEON

R E. MCGUIRE, T. T VON ROSENVINGE, and F. B MACDONALD (NASA, Goddard Space Flight Center, Greenbelt; Maryland, University, College Park, MD) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 65-68 refs

Attempts to systematically measure and fit a large sample of flare spectra from IMP 7 and 8 satellite data to determine the spectral forms that characterize the data and the range of spectral slopes are reported Proton spectra are constructed covering the range 0 9 to over 400 MeV, and alpha fluxes from 1 4-80 MeV/nucleon The event spectra are composed of fluxes measured at different times at each energy, and fitting procedures were employed such as a power law in kinetic energy, an exponential in rigidity, an exponential in energy, and a Bessel function of momentum/nucleon. Best fits were obtained with the exponential in rigidity and the Bessel function, with the Bessel function having a better numerical accuracy for all 21 proton spectra considered

ENERGETIC SOLAR PARTICLE SPECTRA ACCORDING TO VENERA-11, 12 AND PROGNOZ-5, 6

V G KURT, IU I. LOGACHEV, V. G STOLPOVSKII, and E. I. DAIBOG (Moskovskii Gosudarstvennyi Universitet, Moscow, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 69-72. refs

Proton and electron spectra of solar flares measured from 0.1-500 MeV and 0.03-3.0 MeV, respectively, on board the Venera 11, 12, and the Prognoz 5, 6, satellites are reported, along with analyses of the integral peak flux and density dependence in relation to the kinetic energy. All the spectra were fitted by either one or a set of two power functions, with the proton spectra. The number of high energy protons undergoing stochastic particle propagation was found to depend on the shock wave speed. Energy losses were calculated on the basis of deviation from a power law, of a deceleration down to the observation point, and from a numerical estimate of the rate of proton energy change in the adiabatic solar wind expansion An event of Nov 22, 1977 is notable for the absence of protons with energy less than 1 MeV.

A82-22594

EVOLUTION OF THE SOLAR PROTON SPECTRUM IN INTERPLANETARY SPACE

N. N. KONTOR (Moskovskii Gosudarstvennyi Universitet, Moscow, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 73-76. refs

Exponential forms suitable for describing two-three orders wide energy ranges of proton spectra emitted during solar flares are examined. The rigidity exponent form shows a good fit over a broad range except during the onset of a proton shower. A parabolic spectral shape is presented which becomes a power law at narrower energy ranges. Application of the parabolic formula to available flare data reveals that energetic protons arrive first at the detectors, followed by lower energy particles. M S.K.

A DESCRIPTION OF RELATIVISTIC SOLAR PARTICLE PROPAGATION

H DEBRUNNER, H. NEUENSCHWANDER, A. F WAGNER (Bern, Universitaet, Berne, Switzerland), and J A. LOCKWOOD (New Hampshire, University, Durham, NH) In International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 102-105. Research supported by the Swiss National Science Foundation and NSF.

The intensity-time profiles and anisotropies of the solar cosmic-ray ground level events (GLEs) on November 22, 1977 and May 7, 1978 were addressed by means of a Monte Carlo simulation of relativistic solar flare protons propagation in the interplanetary magnetic field. Pitch angle scattering mean free paths of 0.5 AU and more than 3 AU are deduced. The injection of the solar flare protons has an extended time structure, correlated with the X-ray burst profiles in the 1-8 A and 0.5-4.0 A bands, respectively, for the November 1977 and May 1978 GLEs. O.C.

NON-FLARE INJECTION OF PROTONS INTO INTERPLANETARY SPACE

V. DOMINGO, B. SANAHUJA, and K.-P. WENZEL (ESA, Space Science Dept, Noordwijk, Netherlands) In International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 109-112. refs

The superimposition of a second proton population associated with a solar wind regime, and bounded by a pair of shocks, is found to be superimposed upon the first in an investigation of 35-1600 KeV solar protons observed during an April, 1979 nonflare event by ISEE-3 The source of the particles and the solar wind regime appear to be closely associated with intense solar filament activity near the central meridian The temporal evolution of velocity spectra and anisotropy distributions during this period are discussed O.C.

A82-22602

LOW-ENERGY PARTICLES IN INTERPLANETARY MAGNETIC FIELD NEAR THE SECTORIAL BOUNDARY ON SEPTEMBER 26, 1977

M. A ZELDOVICH and B. M KUZHEVSKII (Moskovskii Gosudarstvennyi Universitet, Moscow, USSR) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 113-116 refs

Prognoz-6 data are used to examine effects of the sign reversal in the interplanetary magnetic field of September 26, 1977 on the 70-keV to 40 MeV proton fluxes, and the 10-30 keV and 40-500 keV electron fluxes. The sectorial boundary of interplanetary magnetic field traversed the earth at 2300 UT, and in that period the interplanetary space was filled with the solar cosmic ray particles generated in the flare of September 24, 1977, whose intensity decreased in time. Results indicate that the event of September 26, 1977 was the first observation where effects of the sectorial boundary were traced up to proton energies of 40-50 MeV. DL G

HEAVY-ELEMENT ABUNDANCES IN HE/3/-RICH EVENTS

D. V. REAMES and T. T. VON ROSENVINGE (NASA, Goddard Space Flight Center, Laboratory for High Energy Astrophysics, Greenbelt, MD) In International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 162-165. refs

Abundances of the elements He through Fe observed on the ISEE-3 during He(3) rich events are reported. Ratios of He(3)-He(4) of not less than about 1, and Fe/O of greater than 1 are found, and rather large event-to-event variations in C, O, Ne, Mg, Si, and S are seen superposed upon the general trend of heavy element enhancement. It is concluded that the discontinuous variation of the neighboring elements in the He(3) rich events could result from differences in the electron temperature of the material prior to injection that give rise to differences in the dominant charge states and cyclotron frequencies of different elements. D.L.G.

(Contract BMFT-RV14-B8/74; NAS5-20062)

He isotopes, O and Fe in He(3) rich solar flares are studied during the 1977 to 1979 period with the MPI/UoMd particle experiment on ISEE-1 and ISEE-3. The study revealed that the He(3) spectrum is generally harder than that of He(4), and the O spectrum is harder than that of Fe The spectra are compared with a stationary model based on stochastic Fermi acceleration in Alfven turbulence including a rigidity dependent particle loss. Model calculations fit the He(3) and He(4) spectra between 0.4 and 4.0 MeV/nucleon, with discrepancies at lower and higher energies, and the O and Fe spectra cannot be fitted simultaneously.

STOKER (Potchefstroom University for Christian Higher Education, Potchefstroom, Republic of South Africa) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 193-196. refs

Observations on proton spectra of solar flare GLEs and data from a latitude survey are used to determine specific yield functions for the neutron moderated detector (4NMD) and the 3NM64 neutron monitor at Sanae, Antarctica. Monthly average count rates of the 4NMD and 3NM64 do not follow each other better than 1 percent on long term modulation. No definite physical explanation is singled out to account for the observed excessive variability, which is presumably related to a phase lag effect or hysteresis effect between changes in intensities of particles of different rigidities and the level of solar modulation. CONSIDERATIONS IN USING COLOR INFRARED PHOTOGRAPHS FOR VEGETATIVE INTERPRETATION

P M SEEVERS (U.S. Geological Survey, EROS Data Center, Sioux Falls, SD) In: Color aerial photography in the plant sciences and related fields; Proceedings of the Eighth Biennial Workshop, Luray, VA, April 21-23, 1981 Falls Church, VA, American Society of Photogrammetry, 1981, p. 45-49. refs

The literature suggests that the infrared wavelengths are the most significant when color infrared film records the reflectance of vegetation. Some evidence, however, suggests that the relative sensitivity of the infrared sensitive emulsion layer of the film and the apparent intensity of near infrared reflectance from plants combine to saturate that layer when the film is used to photograph agricultural crops at low altitude. In addition, some physiological considerations of plant characteristics also suggest that the redand green-sensitive emulsion layers would be affected before the infrared-sensitive layer. Observations indicate that tissue damage in most crops is relatively severe before it becomes detectable on color infrared film. It is also then visible to the human eve. This effect suggests that previsual detection of crop damage is not likely on color infrared film. Furthermore, the perceptability of color contrasts by the human eye tends to be a deterrent to visual detection of plant symptoms, both in the field and in the interpretations of color-infrared photographs. MULTI-RESOURCE INVENTORY IN INTERIOR ALASKA

K. M. HEGG (U.S. Forest Service, Washington, DC), F. R LARSON, D. R. MEAD, and K. C WINTERBERGER (Pacific Northwest Forest and Range Experiment Station, Anchorage, AK) In: Color aerial photography in the plant sciences and related fields; Proceedings of the Eighth Biennial Workshop, Luray, VA, April 21-23, 1981. Falls Church, VA, American Society of Photogrammetry, 1981, p. 59-65. refs

Data reduction, conversion, and application of NASA small scale color IR photography for Alaskan renewable resource evaluation are described. The photographs are taken at a 1:120,000 scale, and special overlay ink and film allow suitable definitions of forest and woodland, although brush heights and tundra are undiscernable The study is concentrated along the Susitna River basin, where rapid development is occurring along the road between Anchorage and Fairbanks. Interpretation involves classification of forest, woodland, nonforest, and nonvegetated groups, with forest and woodland further defined into closed or open crown areas, depending on exceeding 50% cover It is recommended that relating ground sample selection based on photopoint interpretation to a digitized map be accomplished by completing the map digitization prior to field plot selection, and statistically tieing photointerpretation sampling schemes to detailed inplace digitized map sampling schemes M.S.K.

APPLICATION OF 35MM COLOR AERIAL PHOTOGRAPHY TO FOREST LAND CHANGE DETECTION

N. L. MILLER and M. P. MEYER (Minnesota, University, St. Paul, MN) In Color aerial photography in the plant sciences and related fields; Proceedings of the Eighth Biennial Workshop, Luray, VA, April 21-23, 1981 Falls Church. VA, American Society of Photogrammetry, 1981, p. 67-72. Research sponsored by the U.S. Forest Service.

Attention is called to the high cost (\$280 per plot) of examining the sample plots that form the data base in forestry surveys. The use of 35-mm color aerial photography for detecting change in these plots is investigated With the method envisaged here, only those sample plots found to be significantly changed (logging, fire, blowdown, insect damage, disease) would be examined, the rest would be updated by computer growth projection models. Trial runs with 35-mm color aerial photography in Minnesota and Michigan yielded good results at a cost estimated at \$20 per plot. C.R.

SPECTRAL SCANNING OF EXPERIMENTAL PLOTS OF SO2-AFFECTED WINTER WHEAT AND SOYBEANS FOR MISSION PLANNING

C D. SAPP (Tennessee Valley Authority, Chattanooga, TN) In: Color aerial photography in the plant sciences and related fields, Proceedings of the Eighth Biennial Workshop, Luray, VA, April 21-23, 1981. Falls Church, VA, American Society of Photogrammetry, 1981, p 101-114. refs

A series of TVA experiments is described wherein plots of soybeans and winter wheat plants were grown to the critical seed-filling stage of development, exposed to controlled doses of SO2, observed systematically for foliar effects, then scanned row by row with a spectroradiometer. The spectral curves were statistically analyzed to determine the changes in spectral reflectance that occur after plants are stressed by SO2 emissions. For soybeans, the affected subplots had higher visible reflectance, lower IR reflectance, and a lower IR/red ratio. Variance analysis showed significant differences in IR and IR/red reflectance, end reflectance, and unaffected ones, and in red reflectance, IR reflectance and IR/red ratio between necrotic and unaffected ones. Since the wheat subplots showed no chlorosis, analysis of reflectance data concentrates on necrosis, which showed a significant difference in red, IR, and IR/red reflectance between classes of differentially injured wheat.

DESERT LOCUST HABITAT MONITORING WITH SATELLITE REMOTE SENSING A NEW TECHNOLOGY FOR AN OLD PROBLEM

J. U. HIELKEMA (United Nations, Food and Agriculture Organization, Rome, Italy) ITC Journal, no 4, 1981, p. 387-417 refs

Precipitation and vegetation remote sensing techniques developed during Phase I of the UN Food and Agricultural Organization program to monitor rainfall and vegetation conditions known to presage desert locust plagues are described. Landsats 2 and 3 multispectral scanners were used, along with Tiros-N and Meteosat and Goes satellite data, to quantify the location, extent, duration, and intensity of rainfall events in the recession area, that region where locusts live as ordinary grasshoppers until conditions which lead to population explosions and subsequent swarming are present. Outbreak areas were sought, along with ecological conditions which induced the outbreaks Landsat data handling procedures are reviewed, and it is noted that mosaic image construction has resulted in the construction of 10 maps for the north Africa locust recession area of Morocco, Algeria, Tunisia, and Libya.

PANORAMIC AERIAL PHOTOGRAPHY IN FOREST PEST MANAGEMENT

W. M. CIESLA (U.S. Forest Service, Fort Collins, CO), R A ALLISON (U.S. Forest Service, Washington, DC), and F. P. WEBER (U.S. Forest Service, Houston, TX) Photogrammetric Engineering and Remote Sensing, vol. 48, May 1982, p. 719-723 refs

The combination of high image resolution and large-area coverage inherent in panoramic photography is shown to make possible 100% coverage of forest pest outbreak areas, as well as the extraction of both stratification and detailed crown counts from a single set of photos. Attention is given to the deployment of the KA-80A optical bar panoramic camera aboard the U-2 high-speed, high-altitude aircraft operated by NASA. Continuous coverage of forested areas allows photos acquired for vegetation damage assessment to be used by such other disciplines as land-use planning, watershed evaluation, road location, or timber-sale planning, suggesting the sharing of photo-acquisition costs. Unfortunately, no aircraft other than the U-2, with its 65,000-foot cruise altitude, is able to use this camera system efficiently.

OPTICAL BAR PANORAMIC PHOTOGRAPHY FOR PLANNING TIMBER SALVAGE IN DROUGHT-STRESSED FORESTS

J. CAYLOR, J PIERCE, and W. SALAZAR (U.S. Forest Service, San Francisco, CA) Photogrammetric Engineering and Remote Sensing, vol. 48, May 1982, p 749-753. refs

Panoramic aerial photographs were obtained over 40 million acres of forest land in northern California during the period July, 1978, through September, 1979 These were used as an aid in planning timber salvage sales to locate concentrations of bark beetle-caused tree mortality following a severe drought. Several innovative procedures devised to effectively use these unconventional format photographs under field conditions are described. The photos were used in 223 salvage sales, resulting in a harvest of 532.2 million board feet of bark beetle killed timber during the period July, 1978, through May 1979. (Author)

EVALUATION OF SPRUCE-FIR FORESTS USING SMALL-FORMAT PHOTOGRAPHS

J. MCCARTHY (Vermont, University, Burlington, VT), C. E OLSON, JR, and J. A WITTER (Michigan, University, Ann Arbor, MI) Photogrammetric Engineering and Remote Sensing, vol. 48, May 1982, p. 771-778 Research supported by the McIntire-Stennis Funds and University of Michigan, U.S. Department of Agriculture refs

(Contract USDA-23-178)

The effectiveness of large-scale, 1 4800 small-format color aerial photographs in the evaluation of tree conditions and identification of the balsam fir and white spruce hosts of the spruce budworm is assessed. Contingency tables allowed comparisons of tree condition and species identification from aerial and ground data. It is shown that photointerpretation of small-format photographs provided mean aerial estimates of tree conditions within one-half of a ranking class of the mean from ground truth data, with balsam fir and white spruce separable at a frequency of 80% and host specie mortality aerial estimates within 10% of the ground test data. THE RESPONSE CHARACTERISTICS OF VEGETATION IN LANDSAT MSS DIGITAL DATA

K. R. MCCLOY (South Australian Institute of Technology, Ingle Farm, Australia) Remote Sensing of Environment, vol. 10, Nov. 1980, p. 185-190. refs

Empirical evidence is used to propose a model of the response due to a vegetative canopy. The model is a simplification, and hence approximation, of the complex relationship between physical conditions in the canopy and the resultant spectral reflectance However, the model can be quantified to yield at least two, and possibly more, independent response parameters from the Landsat response data. These independent response parameters can be used to derive estimates of more than one independent physical characteristic of the canopy. Further, the model specifies its limitations, for a given data input, and indicates how further auxiliary data may be used to extract more information from the model.

A82-32909* National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, Tex. FIELD SIZE, LENGTH, AND WIDTH DISTRIBUTIONS BASED ON LACIE GROUND TRUTH DATA

ON LACIE GROUND TRUTH DATA D. E. PITTS and G. BADHWAR (NASA, Johnson Space Center,

Houston, TX) Remote Sensing of Environment, vol. 10, Nov. 1980, p. 201-213 refs

The development of agricultural remote sensing systems requires knowledge of agricultural field size distributions so that the sensors, sampling frames, image interpretation schemes, registration systems, and classification systems can be properly designed. Malila et al. (1976) studied the field size distribution for wheat and all other crops in two Kansas LACIE (Large Area Crop Inventory Experiment) intensive test sites using ground observations of the crops and measurements of their field areas based on current year rectified aerial photomaps. The field area and size distributions reported in the present investigation are derived from a representative subset of a stratified random sample of LACIE sample segments In contrast to previous work, the obtained results indicate that most field-size distributions are not log-normally distributed. The most common field size observed in this study was 10 acres for most crops studied. G.R

VIEW ANGLE EFFECTS IN THE RADIOMETRIC MEASUREMENT OF PLANT CANOPY TEMPERATURES

D S. KIMES (NASA, Goddard Space Flight Center, Earth Resources Branch, Greenbelt, MD), S B. IDSO, P. J. PINTER, JR, R. J REGINATO, and R. D. JACKSON (U.S Water Conservation Laboratory, Phoenix, AZ) Remote Sensing of Environment, vol. 10, Dec 1980, p 273-284. refs

The thermal infrared sensor response from a wheat canopy was extremely non-Lambertian because of spatial variations in energy flow processes; the effective radiant temperature of the sensor varied as much as 13 C with changing view angle. This variation of sensor response was accurately quantified (root-mean-square of deviations between theoretical and measured responses reduced to 1.1 C) as a function of vegetation canopy geometry, vertical temperature distribution of canopy components, and sensor view angle. The results have important implications for optimizing sensor view angles for remote sensing missions.

A study has been carried out in order to determine the angular limits which should be imposed upon NOAA06 and -7 satellite advanced very high-resolution radiometer (AVHRR) data used in vegetation assessment. The study involved simulations of anticipated sensor output over a wheat crop and empirical investigation of sensor data over vegetated areas. The conclusion drawn from both approaches is that less than 10% variation in

INTERPRETATION OF VEGETATIVE COVER IN WETLANDS USING FOUR-CHANNEL SAR IMAGERY

E WEDLER (Ontario Centre for Remote Sensing, Toronto, Canada) and R. KESSLER (Freiburg, Universitaet, Freiburg im Breisgau, West Germany) In. American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p 111-124. refs

As a part of a Canada-West Germany scientific exchange program, SAR imagery obtained over areas in Southern Ontario was investigated. A unique and varied image response was noted at certain wetland sites. A description is provided of the results of an extension of the early observations to other wetland sites, taking into account preliminary correlations between the SAR image response and the wetland cover type It was found that the effects produced by wetland conditions in Southern Ontario on SAR Xand L-band backscatter make it possible to interpret vegetative cover and moisture conditions from SAR imagery. X-band SAR is sensitive to smaller-scale vegetative content in the wetlands, while L-band SAR is sensitive to larger-scale vegetative content in the wetlands. G R.

PROBLEMS ASSOCIATED WITH REMOTELY DETECTING AND MONITORING SALINE SITES WITHIN IRRIGATED ALBERTA

D. B HARKER (Alberta Agriculture, Irrigation Div, Lethbridge, Canada) In American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p 154-163. refs

Of the 400,000 ha of land irrigated in Alberta, from 10% to 30% has been estimated to be adversely affected by high water tables and soil salinity. To facilitate optimum rehabilitation planning, those lands which are affected or are likely to become affected under new irrigation must be identified and monitored. Over the last 25 years several attempts have been made to identify and monitor affected acreages using panchromatic air photos. Recently, 1:10,000 color and other photographic sensors and scales have been utilized and preliminary work with Landsat digital data has begun In an evaluation of these activities, attention is given to mapping details, mapping efficiency, the affected area, visual pattern recognition problems, and ground truth requirements Plans for future work are also discussed GR.

REMOTE SENSING OF SALT MARSH VEGETATION IN THE FIRST FOUR PROPOSED THEMATIC MAPPER BANDS

J. T. C BUDD (Portsmouth Polytechnic, Portsmouth, England) and E. J. MILTON (Southampton, University, Southampton, England) International Journal of Remote Sensing, vol. 3, Apr -June 1982, p 147-161. Research supported by Portsmouth Polytechnic and University of Reading. refs

The potential of the first four proposed TM bands for estimating above-ground biomass and discriminating species groups was evaluated in an area of intertidal salt marsh in Chichester Harbor, Southern England. Ground spectral data were collected using a portable multiband radiometer during August 1979. The correlation and variance-covariance matrices of the data are shown, as are the results of principal components analysis of the ground spectral data and of canonical variate analysis. Individual sites for four types of algae are graphed for principal components and canonical variates. For biomass estimation, the relationship between bidirectional reflectance and dry biomass is shown for the algae C.D.

THE INFLUENCE OF SOIL CHARACTERISTICS ON REGIONAL CONVECTION DIFFERENCES ABOVE NORTHERN GERMANY [DIE AUSWIRKUNG VON BODENEIGENSCHAFTEN AUF DIE REGIONALEN KONVEKTIONSUNTERSCHIEDE UEBER NORDDEUTSCHLAND]

D. MUELLER and C KOTTMEIER (Hannover, Technische Universitaet, Hanover, West Germany) Meteorologische Rundschau, vol. 35, June 1982, p 84-91 In German. refs

The present investigation is concerned with the various factors which can affect the intensity of convection Soil moisture and orography are found to have significant influence on the convection. Regional differences concerning soil and soil moisture are used as a basis to develop a map which can provide information regarding the local differences of the intensity of convection. The map shows good agreement with observations made by glider pilots above the North German Plain. However, in the mountainous area south of the northern lowlands, orography appears to have a greater effect than soil moisture G.R.

The crop identification procedures used performed were for spring small grains and are conducive to automation. The performance of the machine processing techniques shows a significant improvement over previously evaluated technology, however, the crop calendars require additional development and refinements prior to integration into automated area estimation technology. The integrated technology is capable of producing accurate and consistent spring small grains proportion estimates Barley proportion estimation technology was not satisfactorily evaluated because LANDSAT sample segment data was not available for high density barley of primary importance in foreign regions and the low density segments examined were not judged to give indicative or unequvocal results. Generally, the spring small grains technology is ready for evaluation in a pilot experiment focusing on sensitivity analysis to a variety of agricultural and global meteorological conditions representative of the environment. Day-IR, day-visible, and night-IR image data sets were analyzed. All three images were contrast enhanced, using a linear stretch. The night-IR image was destriped using a box-car filtering approach. Apparent thermal inertia images were generated from the data. The enhanced data and the apparent thermal inertia image were also registered and overlayed onto shaded relief images depicting topography and onto a colored version of the Missouri geologic map. The combination of the apparent thermal inertial image and the shaded relief map proved to have the greatest discriminability in terms of portraying linear features. The reason seems to be that the vegetation canopy on the Ozark Plateau is different topography, tend to emphasize subtle topographic effects.

AGRISTARS: FOREIGN COMMODITY PRODUCTION FORECASTING. THE 1980 US CORN AND SOYBEANS EXPLORATORY EXPERIMENT Final Report

J T. MALIN and J G. CARNES, Principal Investigators Oct. 1981 183 p refs Sponsored by NASA, USDA, Dept of Commerce, Dept. of the interior and Agency for International Development ERTS

(Contract NAS9-15800, PROJ. AGRISTARS)

(E82-10206; NASA-CR-167485, JSC-17138; NAS 1.26:167485, LEMSCO-16573; FC-L1-04096) Avail: NTIS HC A09/MF A01

CSCL 02C The U.S corn and soybeans exploratory experiment is described which consisted of evaluations of two technology components of a production forecasting system: classification procedures (crop labeling and proportion estimation at the level of a sampling unit) and sampling and aggregation procedures. The results from the labeling evaluations indicate that the corn and soybeans labeling

procedure works very well in the U.S. corn belt with full season

01 AGRICULTURE AND FORESTRY

(after tasseling) LANDSAT data. The procedure should be readily adaptable to corn and soybeans labeling required for subsequent exploratory experiments or pilot tests. The machine classification procedures evaluated in this experiment were not effective in improving the proportion estimates The corn proportions produced by the machine procedures had a large bias when the bias correction was not performed. This bias was caused by the manner in which the machine procedures handled spectrally impure pixels. The simulation test indicated that the weighted aggregation procedure performed guite well. Although further work can be done to improve both the simulation tests and the aggregation procedure, the results of this test show that the procedure should serve as a useful baseline procedure in future exploratory experiments and M.G. pilot tests.

N82-23580*# Department of Agriculture, Houston, Tex EVALUATION OF THE DORAISWAMY-THOMPSON WINTER WHEAT CROP CALENDAR MODEL INCORPORATING A MODIFIED SPRING RESTART SEQUENCE

(Contract PROJ. AGRISTARS)

(E82-10207, NASA-CR-167486; JSC-17801; NAS 1 26:167486, EW-U1-04212) Avail NTIS HC A02/MF A01 CSCL 02C

The Robertson phenology was used to provide growth stage information to a wheat stress indicator mode. A stress indicator model demands two acurate predictions from a crop calendar. date of spring growth initiation; and crop calendar stage at growth initiation. Several approaches for restarting the Robertson phenology model at spring growth initiation were studied. Although best results were obtained with a solar thermal unit method, an alternate approach which indicates soil temperature as the controlling parameter for spring growth initiation was selected and tested. The modified model (Doraiswamy-Thompson) is compared to LACIE-Robertson model predictions Ė.A.K.

(E82-10208; NASA-CR-167487, JSC-16858, NAS 1 26.167487; LEMSCO-16018; SR-L1-04032) Avail: NTIS HC A03/MF A01 CSCL 02C

A model was developed using 996 planting dates at 51 LANDSAT segments for spring wheat and spring barley in Minnesota, Montana, North Dakota, and South Dakota in 1979 Daily maximum and minimum temperatures and precipitation were obtained from the cooperative weather stations nearest to each segment. The model uses a growing degree day summation modified for daily temperature range to estimate the beginning of planting and uses a soil surface wetness variable to estimate how a fixed number of planting days are distributed after planting begins For 1979, the model predicts first, median, and last planting dates with root mean square errors of 7.91, 6 61, and 7.09 days, respectively. The model also provides three or four dates to represent periods of planting activity within the planting season. Although the full model was not tested on an independent data set, it may be suitable in areas other than the U.S. Great Plains where spring small grains are planted as soon as soil and air temperatures become warm enough in the spring for plant growth. LARS-101281) Avail: NTIS HC A04/MF A01 CSCL 02C

Several levels of obtaining both area and yield estimates are considered: county, refined strata, refined/split strata, crop reporting district, and state Using the CCEA model form and smoothed weather data, regression coefficients at each level were derived to compute yield and its variance. The variance of the yield estimates was largest at the state and smallest at the county level for the two crops studied corn and soybeans. The refined strata had somewhat larger variances than those associated with the refined/split strata and CRD. For production estimates, the difference in standard deviations among levels was not large for corn, but for soybeans the standard deviation at the state level was more than 50% greater than for the other levels. The refined strata had the smallest standard deviations T.M. **N82-23589*#** National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, Tex.

AGRISTARS. PRELIMINARY TECHNICAL RESULTS REVIEW OF FY81 EXPERIMENTS, VOLUME 2: FISCAL YEAR 1981/1982 'CORN AND SOYBEANS PILOT' EXPERIMENT

29 Sep. 1981 170 p Sponsored by NASA, USDA, Dept. of Commerce, Dept of the Interior, and Agency for International Development ERTS

(E82-10217; NASA-CR-167479; JSC-17440, NAS 1.26:167479; LEMSCO-16935, FC-L1-04192) Avail NTIS HC A02/MF A01 CSCL 02C

A technique is presented which estimates pan evaporation from the commonly observed values of daily maximum and minimum air temperatures. These two variables are transformed to saturation vapor pressure equivalents which are used in a simple linear regression model. The model provides reasonably accurate estimates of pan evaporation rates over a large geographic area The derived evaporation algorithm is combined with precipitation to obtain a simple moisture variable. A hypothetical medium with a capacity of 8 inches of water is initialized at 4 inches. The medium behaves like a sponge: it absorbs all incident precipitation, with runoff or drainage occurring only after it is saturated. Water is lost from this simple system through evaporation just as from a Class A pan, but at a rate proportional to its degree of saturation The contents of the sponge is a moisture index calculated from only the maximum and minium temperatures and precipitation. The feasibility of using the principles of computer axial topography (CAT) to quantify the structure of crop canopies was investigated because six variables are needed to describe the position-orientation with time of a small piece of canopy foliage Several cross sections were cut through the foliage of healthy, green corn and soybean canopies in the dent and full pod development stages, respectively. A photograph of each cross section representing the intersection of a plane with the foliage was enlarged and the air-foliage boundaries delineated by the

plane were digitized. A computer program was written and used to reconstruct the cross section of the canopy. The approach used in applying optical computer axial tomography to measuring crop canopy geometry shows promise of being able to provide needed geometric information for input data to canopy reflectance models. The difficulty of using the CAT scanner to measure large canopies of crops like corn is discussed and a solution is proposed involving the measurement of plants one at a time A R.H.

(E82-10229; NASA-CR-167419, NAS 1.26:167419,

LARS-TR-090981; SR-P1-04139) Avail NTIS HC A02/MF A01 CSCL 20F

The linear polarization and reflection of visible light by wheat as a function of sun-view diections, crop development stage, and wavelength were examined. Two-hundred spectra were taken continuously in wave-lengths from 0.45 to 0.72 Micron in 33 view directions using an Exotech model 20C spectroradiometer six meters above two wheat canopies in the boot and fully headed maturity stages. The analysis results show that the amount of linearly polarized light from the wheat canopies is greatest in the blue spectral region and decreases gradually with increasing wavelength. The results also show that the linearly polarized light from the canopies is generally greatest in the azimuth direction of the Sun and tends toward zero as the view direction tends toward the direction of the hot spot or anti-solar point. It is demonstrated that the single, angle of incidence of sunlight on the leaf, explains almost all of the variation of the amount of polarized light with Sun-view direction M.G

EVALUATION OF THE PROCEDURE FOR SEPARATING BARLEY FROM OTHER SPRING SMALL GRAINS

E R. MAGNESS, Principal Investigator Aug. 1980 77 p refs Sponsored by NASA, USDA, Dept. of Commerce, Dept. of the Interior, and Agency for International Development ERTS (Contract NAS9-15800; PROJ. AGRISTARS)

(E82-10230; NASA-CR-160888; JSC-16752, NAS 1.26.160888, LEMSCO-14598; FC-LO-00472) Avail: NTIS HC A05/MF A01 CSCL 02C

The success of the Transition Year procedure to separate and label barley and the other small grains was assessed. It was decided that developers of the procedure would carry out the exercise in order to prevent compounding procedural problems with implementation problems. The evaluation proceeded by labeling the sping small grains first. The accuracy of this labeling was, on the average, somewhat better than that in the Transition Year operations. Other departures from the original procedure included a regionalization of the labeling process, the use of trend analysis, and the removal of time constraints from the actual processing. Segment selection, ground truth derivation, and data available for each segment in the analysis are discussed. Labeling accuracy is examined for North Dakota, South Dakota, Minnesota, and Montana as well as for the entire four-state area. Errors are characterized. A.R H

A MODEL OF PLANT CANOPY POLARIZATION

V. C. VANDERBILT Jun. 1980 12 p refs Repr from Machine Process. of Remotely Sensed Data, Jun 1980 p 98-108 Sponsored by NASA, USDA, Dept of Commerce, Dept. of the Interior, and Agency for International Development ERTS (Contract NAS9-15466, PROJ AGRISTARS)

(E82-10233; NASA-CR-167415; SR-P1-04170; NAS 1.26:167415;

LARS-060580) Avail: NTIS HC A02/MF A01 CSCL 20F

A model for the amount of linearly polarized light reflected by the shiny leaves of grain crops is based on the morphological and phenological characteristics of the plant canopy and upon the Fresnel equations which describe the light reflection process at the smooth boundary separating two dielectrics. The theory used demonstrates that, potentially, measurements of the linearly polarized light from a crop canopy may be used as an additional feature to discriminate between crops such as wheat and barley, two crops which are so spectrally similar that they are misclassified with unacceptable frequency Examination of the model suggests that, potentially, satellite polarization measurements may be used to monitor crop development stage, leaf water content, leaf area index, hail damage, and certain plant diseases. The information content of these measurements is needed to evaluate the proposed polarization sensor for the satellite-borne multispectral resource sampler. A.R H

The interaction of the solar illumination angle and row azimuth angle of the measured reflectance factor (RF) of soybean canopies was investigated Diurnal changes of nearly 140% were observed in the red wavelength region when canopies covered 64% of the soil. The amount of shadow observed was a function of the plant geometry and row width. As soil cover approached 100%, the diurnal changes diminished. A function tht describes the solar illumination angle with respect to the row azimuth explained most of the diurnal variation in the measured RF. Variation in near

01 AGRICULTURE AND FORESTRY

infrared response was much less and did not appear to be as strongly related to Sun-row angle interactions. The near infrared/red ratio was highly sensitive to Sun angle-row direction interactions, whereas the greenness function, utilizing all four spectral bands, was not. J.D.

(E82-10238, NASA-TM-83842; SM-GI-04178; NAS 1.15.83842) Avail. NTIS HC A02/MF A01 CSCL 08M

A USDA Beltsville Agricultural Research Center site was used for an experiment in which soil moisture remote sensing over bare, grass, and alfalfa fields was conducted over a three-month period using 0.6 GHz, 1.4 GHz, and 10.6 GHz Dicke-type microwave radiometers mounted on mobile towers. Ground truth soil moisture content and ambient air and sil temperatures were obtained concurrently with the radiometric measurements. Biomass of the vegetation cover was sampled about once a week. Soil density for each of the three fields was measured several times during the course of the experiment. Results of the radiometric masurements confirm the frequency dependence of moisture sensing sensitivity reduction reported earlier Observations over the bare, wet field show that the measured brightness temperature is lowest at 5.0 GHz and highest of 0.6 GHz frequency, a result contrary to expectation based on the estimated dielectric permittivity of soil water mixtures and current radiative transfer model in that frequency range. Progress and technical issues are reported in the development of corn/soybeans area estimation procedures for use on data from South America, with particular emphasis on Argentina Aspects related to the supporting research section of the AgRISTARS Project discussed include: (1) multisegment corn/soybean estimation, (2) through the season separability of corn and soybeans within the U.S corn belt, (3) TTS estimation; (4) insights derived from the baseline corn and soybean procedure; (5) small fields research, and (6) simulating the spectral appearance of wheat as a function of its growth and development. To assist the foreign commodity production forecasting, the performance of the baseline corn/soybean procedure was analyzed and the procedure modified Fundamental limitations were found in the existing guidelines for discriminating these two crops. The temporal and spectral characteristics of corn and soybeans must be determined because other crops grow with them in Argentina. The state of software technology is assessed and the use of profile techniques for estimation is considered. A.R.H.

A ground and aircraft program was conducted to extend ground based methods for measuring soil moisture and crop water stress to aircraft and satellite altitudes A 260ha agricultural field in California was used over the 1977-78 growing season For cloud free days ground based temperature measurements over bare soil were related to soil moisture content. Water stress resulted from too much water, not from lack of it, as was expected A theoretical examination of the canopy air temperature difference as affected by vapor pressure deficit and net radiation was developed This analysis shows why surface temperatures delineate crop water stress under conditions of low humidity, but not under high humidity conditions. Multilevel temperatures acquired from the ground, low and high altitude aircraft, and the Heat Capacity Mapping Mission (HCMM) spacecraft were compared for two day and one night overpasses The U-2 and low altitude temperatures were within 0.5 C The HCMM data were analyzed using both the pre- and post-launch calibrations, with the former being considerably closer in agreement with the aircraft data than the latter M.G.

AN ANALYSIS OF LANDSAT MSS SCENE-TO-SCENE **REGISTRATION ACCURACY**

B. R SEYFARTH and P. W COOK, Principal Investigators (USDA) Dec 1981 14 p Sponsored by NASA, USDA, Dept. of Commerce, Dept of Interior, and Agency for International Development ERTS

(Contract PROJ AGRISTARS)

(E82-10285; NASA-TM-84694; DC-Y1-04156, NSTL/ERL-198;

NAS 1.15.84694) Avail: NTIS HC A02/MF A01 CSCL 02C

Measurements were made for 12 registrations done by ERL for 8 registrations done by SRS. The results indicate that the ERL method is significantly more accurate in five of the eight comparison. The difference between the two methods are not significant in the other three cases There are two possible reasons for the differences. First, the ERL model is a piecewise linear model and the EDITOR model is a cubic polynomial model Second, the ERL program resamples using bilinear interpolation while the EDITOR software uses a nearest neighbor resampling. This study did not indicate how much of the difference is attributable to each factor. The average of all merged scene error values for ERL was 31.6 meters and the average for the eight common areas was 32.6 meters The average of the eight merged scene error values for SRS was 40 1 meters. (Contract PROJ. AGRISTARS)

(E82-10287; NASA-TM-84696; RR-Y1-04217, NSTL/ERL-202, NAS 1 15:84696) Avail: NTIS HC A03/MF A01 CSCL 05B

Digital processed aircraft-acquired thematic mapping simulator (TMS) data collected during the winter season over a forested site in southern Mississippi are presented to investigate the utility of TMS data for use in forest inventories and monitoring Analyses indicated that TMS data are capable of delineating the mixed forest land cover type to an accuracy of 92.5 % correct. The accuracies associated with river bottom forest and pine forest were 95.5 and 91.5 % correct. The accuracies associated with river bottom forest and pine forest were 95.5 and 91 5 % correct, respectively. The figures reflect the performance for products produced using the best subset of channels for each forest cover type. It was found that the choice of channels (subsets) has a significant effect on the accuracy of classification produced, and that the same channels are not the most desirable for all three forest types studied. Both supervised and unsupervised spectral signature development techniques are evaluated, the unsupervised methods proved unacceptable for the three forest types considered. E.A K

DELINEATION OF SOIL TEMPERATURE REGIMES FROM HCMM DATA Quarterly Report

R. L. DAY and G W. PETERSEN, Principal Investigators 31 Mar. 1982 3 p refs HCMM

(E82-10298; NASA-CR-168867; NAS 1 26 168867) Avail. NTIS HC A02/MF A01 CSCL 08M

The subsetting of HCMM data into ORSER format was completed for four dates using a modified SUBSET program. Large areas (approximately 2500 scan lines, 1680 elements) were selected to increase the occurrrence of suitable control points for registration Average daily temperatures (ADT) were calculated for each date. The MERGE program combined registered daytime temperature (DAY-IR) with nighttime temperature (NIGHT-IR) to form a separate two-channel data set The SUBTRAN program averaged the DAY-IR and NIGHT-IR creating a third ADT channel. Registration equations for the four ADT data sets were generated. A one dimensional soil heat flow equation was modified to allow for mean annual soil temperature predictions using merged ADT data sets A.R.H.

USE OF THERMAL INERTIA DETERMINED BY HCMM TO PREDICT NOCTURNAL COLD PRONE AREAS IN FLORIDA Quarterly Report, 16 Sep. - 15 Dec. 1981

L. H ALLEN, JR., Principal Investigator, E CHEN, J. D. MARTSOLF, and P. H. JONES 15 Dec 1981 15 p refs HCMM

(Contract NAS5-26453)

(E82-10299; NASA-CR-168868; NAS 1 26:168868) Avail NTIS HC A02/MF A01 CSCL 04B

Surface temperatures derived from HCMM data were compared with to those obtained by GOES satellite and the apparent thermal inertia (ATI) calculated. For two dates, the HCMM temperatures appear to be about 5 C lower than the GOES temperatures. The ATI for excessively-drained to well-drained mineral soils was greater than for drained organic soils possibly because of long periods of low rainfall during late 1980 and early 1981 Organic soils cropped to sugar cane showed lower ATI after a severe killing freeze. With dead leaves, there was less transpiration and more solar radiation probably reached the dark soil surface. This would explain the larger diurnal temperature amplitude observed. A.R.H.

N82-24576*# Instituto Geografico Nacional, Madrid (Spain). THERMAL MAPPING, GEOTHERMAL SOURCE LOCATION, NATURAL EFFLUENTS AND PLANT STRESS IN THE MEDITERRANEAN COAST OF SPAIN Final Report, Sep. 1978 - Aug. 1980

A METHOD FOR INFERRING AVAILABLE SURFACE MOISTURE USING REMOTE SURFACE TEMPERATURE MEASUREMENTS: AN ASSESSMENT

T. N. CARLSON, Principal Investigator Feb 1982 33 p refs Sponsored by NASA ERTS

(E82-10311; NASA-CR-168886; NAS 1.26 168886) Avail: NTIS HC A03/MF A01 CSCL 08M

A method for inferring surface moisture availability, which combines a numerical boundary layer model with remote estimates of surface-temperature, is evaluated with regard to its ability to provide significant results. Some analyses of surface moisture availability based on GOES and on HCMM surface temperature measurements are presented for an urban area (St. Louis) and for a drought situation over Kansas Patterns of moisture availability clearly indicate a relationship between land use, particularly vegetation cover, and derived moisture availability over urban areas and also suggest a relationship between antecedent rainfall and derived moisture availability over vegetated regions. Soil moisture in the 0-cm to 4-cm layer could be estimated with 1-mm soil temperatures throughout the growing season of a rainfed barley crop in eastern South Dakota Empirical equations were developed to reduce the effect of canopy cover when radiometrically estimating the soil temperature. Corrective equations were applied to an aircraft simulation of HCMM data for a diversity of crop types and land cover conditions to estimate the soil moisture. The average difference between observed and measured soil moisture was 1.6% of field capacity. Shallow alluvial aquifers were located with HCMM predawn data. After correcting the data for vegetation differences, equations were developed for predicting water table depths within the aquifer. A finite difference code simulating soil moisture and soil temperature shows that soils with different moisture profiles differed in soil temperatures in a well defined functional manner A significant surface thermal anomaly was found to be associated with shallow water tables. A sensor/scene simulation program was developed and used to determine the effects of scene heterogeneity, resolution, frequency, look angle, and surface and temperature relations on the performance of a spaceborne passive microwave system designed to estimate soil water information. The ground scene is based on classified LANDSAT images which provide realistic ground classes, as well as geometries. It was determined that the average sensitivity of antenna temperature to soil moisture improves as the antenna footprint size increased. Also, the precision (or variability) of the sensitivity changes as a function of resolution M.G

PLAN OF RESEARCH FOR INTEGRATED SOIL MOISTURE STUDIES. RECOMMENDATIONS OF THE SOIL MOISTURE WORKING GROUP

Oct. 1980 111 p refs

(NASA-TM-84731; NAS 1.15 84731) Avail NTIS HC A06/MF A01 CSCL 08M

Soil moisture information is a potentially powerful tool for applications in agriculture, water resources, and climate At present, it is difficult for users of this information to clearly define their needs in terms of accuracy, resolution and frequency because of the current sparsity of data. A plan is described for defining and conducting an integrated and coordinated research effort to develop and refine remote sensing techniques which will determine spatial and temporal variations of soil moisture and to utilize soil moisture information in support of agricultural, water resources, and climate applications The soil moisture requirements of these three different application areas were reviewed in relation to each other so that one plan covering the three areas could be formulated. Four subgroups were established to write and compile the plan, namely models, ground-based studies, aircraft experiments, and spacecraft missions A.R.H.

LARS-030182) Avail. NTIS HC A02/MF A01 CSCL 20F

Reflectance factor data were accquired with a Landsat band radiometer throughout two growing seasons for corn (Zea mays L.) canopies differing in planting dates, populations, and soil types. Agronomic data collected included leaf area index (LAI), biomass, development stage, and final grain yields The spectral variable, greenness, was associated with 78 percent of the variation in LAI over all treatments Single observations of LAI or greenness have limited value in predicting corn yields. The proportions of solar radiation intercepted (SRI) by these canopies were estimated using either measured LAI or greenness Both SRI estimates, when accumulated over the growing season, accounted for approximately

65 percent of the variation in yields. Models which simulated the daily effects of weather and intercepted solar radiation on growth had the highest correlations to grain yields. This concept of estimating intercepted solar radiation using spectral data represents a viable approach for merging spectral and meteorological data for crop yield models. Author

EVALUATION OF THE SOIL MOISTURE PREDICTION ACCURACY OF A SPACE RADAR USING SIMULATION TECHNIQUES Final Report

F. T. ULABY, Principal Investigator, M. C. DOBSON, J. A. STILES, R. K MOORE, and J. C. HOLTZMAN May 1981 208 p refs Original contains imagery. Original photography may be purchased from the EROS Data Center, Sioux Falls, S.D. 57198 ERTS (Contract NAS5-25807)

(E82-10351; NASA-CR-166801; NAS 1.26:166801; RSL-TR-429-1) Avail: NTIS HC A10/MF A01 CSCL 08M

Image simulation techniques were employed to generate synthetic aperture radar images of a 17.7 km x 19.3 km test site located east of Lawrence, Kansas The simulations were performed for a space SAR at an orbital altitude of 600 km, with the following sensor parameters. frequency = 4.75 GHz, polarization = HH, and angle of incidence range = 7 deg to 22 deg from nadir. Three sets of images were produced corresponding to three different spatial resolutions; 20 m x 20 m with 12 looks, 100 m x 100 m with 23 looks, and 1 km x 1 km with 1000 looks Each set

consisted of images for four different soil moisture distributions across the test site. Results indicate that, for the agricultural portion of the test site, the soil moisture in about 90% of the pixels can be predicted with an accuracy of = + or - 20% of field capacity Among the three spatial resolutions, the 1 km x 1 km resolution gave the best results for most cases, however, for very dry soil conditions, the 100 m x 100 m resolution was slightly superior.

MAPPING OF WILDLIFE HABITAT IN FARMINGTON BAY, UTAH

R. A JAYNES and R. D. WILLIE, Principal Investigators 1982 15 p refs ERTS

(Contract NAGW-95)

(E82-10354; NASA-CR-168975; NAS 1.26:168975, CRSC-82-1) Avail NTIS HC A02/MF A01 CSCL 08B

Mapping was accomplished through the interpretation of high-altitude color infrared photography. The feasibility of utilizing LANDSAT digital data to augment the analysis was explored; complex patterns of wildlife habitat and confusion of spectral classes resulted in the decision to make limited use of LANDSAT data in the analysis. The final product is a map which delineates wildlife habitat at a scale of 1.24,000. The map is registered to and printed on a screened U S G S. quadrangle base map. Screened delineations of shoreline contours, mapped from a previous study, are also shown on the map Intensive field checking of the map was accomplished for the Farmington Bay Waterfowl Management Area in August 1981; other areas on the map received only spot field checking.

DETECTION OF VARIATIONS IN ASPEN FOREST HABITAT FROM LANDSAT DIGITAL DATA: BEAR RIVER RANGE, UTAH

J A MEROLA and R. A JAYNES, Principal Investigators 17 Mar. 1982 34 p refs Sponsored in part by US Forest Service ERTS

(Contract NAGW-95; NSF SPI-80-03978)

(E82-10355; NASA-CR-168976; NAS 1.26.168976; CRSC-82-2) Avail: NTIS HC A03/MF A01 CSCL 02F

The aspen forests of the Bear River Range were analyzed and mapped using data recorded on July 2, 1979 by the LANDSAT III satellite; study efforts yielded sixty-seven light signatures for the study area, of which three groups were identified as aspen and mapped at a scale of 1 24,000. Analysis and verification of the three groups were accomplished by random location of twenty-six field study plots within the LANDSAT-defined aspen areas All study plots are included within the Cache portion of the Wasatch-Cache National Forest. The following selected site characteristics were recorded for each study plot: a list of understory species present, average percent cover density for understory species; aspen canopy cover estimates and stem measurements; and general site topographic characteristics The study plot data were then analyzed with respect to corresponding Landsat spectral signatures. Field studies show that all twenty-six study plots are associated with one of the three aspen groups. Further study efforts concentration on characterizing the differences between the site characteristics of plots falling into each of the three aspen groups Author

The irrigated cropland in the Bear River Basin as of the 1975 growing season was inventoried from satellite imagery LANDSAT color infrared images (scale 1 125,000) were examined for early, mid, and late summer dates, and acreage was estimated by use of township/section overlays. The total basin acreage was estimated to be 573,435 acres, with individual state totals as follows: Idaho 234,370 acres, Utah 265,505 acres, and Wyoming 73,560 acres As anticipated, wetland areas intermingled among cropland appears to have produced an over-estimation of irrigated acreage. According to a 2% random sample of test sites evaluated by personnel from the Soil Conservation Service such basin-wide over-estimation is 7.5%; individual counties deviate significantly from the basin-wide figure, depending on the relative amount of wetland areas intermingled with cropland. Two visible/near IR hand held radiometers and a hand held thermoradiometer were used along with soil moisture and lysimetric measurements in a study of soil moisture distribution in afalfa fields on the Navajo Indian Irrigation Project near Farmington, New Mexico. Radiances from irrigated plots were measured and converted to reflectances. Surface soil water contents (o cm to 4 cm) were determined gravimetrically on samples collected at the same time as the spectral measurements. The relationship between the spectral measurements and the crop coefficient were evaluated to demonstrate potential for using spectral measurement to estimate crop coefficient EA.K.

MULTIFREQUENCY REMOTE SENSING OF SOIL MOISTURE Final Report

S. W THEIS, M. J MCFARLAND, W D. ROSENTHAL, and C. L JONES, Principal Investigator Feb. 1982 145 p refs ERTS (Contract NSG-5134)

(E82-10362; NASA-CR-169011, NAS 1 26.169011,

RSC-3458-129) Avail. NTIS HC A07/MF A01 CSCL 08M

Multifrequency sensor data collected at Guymon, Oklahoma and Dalhart, Texas using NASA's C-130 aircraft were used to determine which of the all-weather microwave sensors demonstrated the highest correlation to surface soil moisture over optimal bare soil conditions, and to develop and test techniques which use visible/infrared sensors to compensate for the vegetation effect in this sensor's response to soil moisture. The L-band passive microwave radiometer was found to be the most suitable single sensor system to estimate soil moisture over bare fields. In comparison to other active and passive microwave sensors the L-band radiometer (1) was influenced least by ranges in surface roughness, (2) demonstrated the most sensitivity to soil moisture differences in terms of the range of return from the full range of soil moisture; and (3) was less sensitive to errors in measurement in relation to the range of sensor response. L-band emissivity related more strongly to soil moisture when moisture was expressed as percent of field capacity. The perpendicular vegetation index as determined from the visible/infrared sensors was useful as a measure of the vegetation effect on the L-band radiometer response to soil moisture. A R.H.

DEVELOPMENT OF VISIBLE/INFRARED/MICROWAVE AGRICULTURE CLASSIFICATION AND BIOMASS ESTIMATION ALGORITHMS Final Report

W. D. ROSENTHAL, M J MCFARLAND, S. W. THEIS, and C. L JONES, Principal Investigtors Feb. 1982 221 p refs ERTS (Contract NSG-5134)

(E82-10363, NASA-CR-169012) Avail: NTIS HC A10/MF A01 CSCL 02C

Agricultural crop classification models using two or more spectral regions (visible through microwave) are considered in an effort to estimate biomass at Guymon, Oklahona Dalhart, Texas Both grounds truth and aerial data were used Results indicate that inclusin of C, L, and P band active microwave data, from look angles greater than 35 deg from nadir, with visible and infrared data improve crop discrimination and biomass estimates compared to results using only visible and infrared data. The microwave frequencies were sensitive to different biomass levels. The K and C band were sensitive to differences at low biomass levels, while P band was sensitive to differences at high biomass levels. Two indices, one using only active microwave data and the other using data from the middle and near infrared bands, were well correlated to total biomass. It is implied that inclusion of active microwave sensors with visible and infrared sensors on future satellites could aid in crop discrimination and biomass estimation. E.A.K.

THE USE OF SOIL TEXTURE AND FIELD CAPACITY TO NORMALIZE MICROWAVE SOIL MOISTURE MEASUREMENTS: SOME PROBLEMS M.S. Thesis

R. D. LEES May 1982 72 p refs Sponsored by Texas A & M Univ.

Avail: NTIS HC A04/MF A01

Soil moisture normalizing techniques attempt to explain variations in soil-water content between soils in terms of soil texture based on the percent sand, silt and clay in the soil. A critical analysis of these techniques was made to examine their effectiveness in comparing soils of varying texture and soil moisture content in relation to their microwave (radar) backscatter While the particle size distribution is recognized as a significant factor in the soil-water relationship, its influence is regulated by a number of other factors. Results indicate that 'normalization' by use of field capacity - derived from the percentages of sand, silt and clay - actually reduced the sensitivity of backscattering coefficient to soil-water content. The water holding capacity of soils is variably influenced by properties such as soil structure, clay mineral type, organic matter content, aeration, soil layering, and hysteresis and related water addition and extraction processes. DEPENDENCE OF EARTH SPECTRUM OF POSITRONS AND ANTIPROTONS ON PROPAGATION MODELS

S A STEPHENS (Tata Institute of Fundamental Research, Bombay, India) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 214-217 refs

A calculation of the equilibrium spectra of positrons and antiprotons for different models are presented. A total of five propagation models is considered, comprising a simple leak box, a modified leaky box, a nested leaky box, a simple closed galaxy, and a modified closed galaxy The antiproton spectrum is noted to be dependent only on the propagation model and not on the solar modulation, which supports the use of an antiproton spectrometer in monitoring the degree of solar modulation Kinetic energy fluxes are determined for the two components as predicted for each model, and observed antiproton fluxes are shown to rule out the modified and nested leaky box models. The modified closed galaxy model is found to accurately predict solar modulation from low energy data, and positron data at high energies is taken to quantify the mean gas density in a region of total confinement to be 0 05 atoms/cu cm. ON THE STELLAR ORIGIN OF LOW ENERGY COSMIC RAYS

S BISWAS, N DURGAPRASAD, and S S TRIVEDI (Tata Institute of Fundamental Research, Bombay, India) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 314-317 refs

The hypothesis is proposed that energetic ions of He, C, N, O, etc., in the low energy (1 to 50 MeV/amu) anomalous component of cosmic rays, originate from O-type stars which manifest very strong stellar winds with very high mass loss rates of about 3 x 10 to the -6th solar mass/yr These have terminal velocities of 1200-4000 km/s which are typically several times their escape velocities. These velocities correspond to ion energies of 10 to 200 keV/amu. These ions of energy of about 100 keV/amu are in partly ionized states and are accelerated in the interstellar shock fronts to about 10 MeV/amu, thus accounting for the observed anomalous component of low-energy cosmic rays (Author)

REMARKS ON COSMIC RAY ORIGIN

V. L. GINZBURG (Akademia Nauk SSSR, Fizicheskii Institut, Moscow, USSR) and V. S PTUSKIN (Akademiia Nauk SSSR, Institut Zemnogo Magnetizma lonosfery i Rasprostraneniia Radiovoln, Troitsk, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 336-339. refs

Various problems related to current work on the origins of cosmic rays are considered. The acceleration of cosmic ray particles at the spherical front of an interstellar shock wave is analyzed, and a value of 10 to the 12th eV is obtained for the upper limit to accelerated particle energies. Transport in the Galaxy by means of large-scale turbulent motions is shown to produce a cosmic ray diffusion coefficient that is too low, while acceleration due to scattering by isotropic magnetohydrodynamic turbulence is also small A possible method for the estimation of the contribution of local sources to cosmic ray concentrations observed near the earth is also presented, and possible explanations are suggested for the recent gamma ray observations of lowered cosmic ray electron concentrations at a distance less than 2 kpc from the galactic center.

PULSAR MODELS AND COSMIC-RAY ACCELERATION

F. C. MICHEL and A. J DESSLER (Rice University, Houston, TX) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 340-343. refs

It is argued that radio pulsars and X-ray pulsars differ mainly in the fact that the the latter are surrounded by an inward moving accretion disk while the former are surrounded by an outward moving fossil collapse disk presumably left over from the formation event. Cosmic rays of more-or-less 'solar' composition can be accelerated to energies of 10 to the 20th eV shortly after the formation event. (Author)

SOLAR GAMMA-RAY EXPERIMENT ON ASTRO-A SATELLITE K. OKUDAIRA, Y HIRASIMA, M. YOSHIMORI (Rikkyo University, Tokyo, Japan), and I. KONDO (Tokyo, University, Tanashi, Japan) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 11-14 refs

The instrumentation and performance parameters of the Japanese Astro-A satellite for measuring solar gamma ray lines and continua associated with solar flares are described. A gamma ray spectrometer which is a phoswich scintillator covers the gamma ray range from 0.24-6.48 MeV with a resolution of 10 percent at 662 keV. Techniques to discern gamma ray from particle events are discussed, along with the 128 channel pulse height analyzer

with three regions for the pulse height spectrum. Low bit rates are recorded during quiet modes, and high speed rates are enacted during a solar flare. The spacecraft was launched in Feb 1981 and is in-flight calibrated by reference to the atmospheric positron annihilation line at 0.51 MeV M.S K

A82-22588

HIGH-ENERGY SOLAR PROTONS

N. N VOLODICHEV and I. A SAVENKO (Moskovskii Gosudarstvennyi Universitet, Moscow, USSR) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 45-48. refs

Evidence is presented for a second particle acceleration phase following the explosive phase of a solar flare. Cerenkov and scintillation counters were employed on the Prognoz satellite to detect the arrival of protons with energies greater than 100 MeV or 500 MeV, respectively. Delays of several minutes to several tens of minutes were observed for the arrival of protons from radiobursts in the cm range and X ray bursts during solar flare activity A similar delay was recorded on the Proton-3 satellite during a burst event of Nov. 22, 1977, using the same measurement techniques. The existence of a second acceleration phase, when protons are accelerated to high energies and electrons up to relativistic energies, is noted to not contradict a model of the explosive phase of the flare as a process of disappearance and break of the current layer in the region of a highly dense plasma M.S.K.

A82-22605* Maryland Univ, College Park. TIME AND ENERGY DEPENDENCE OF HEAVY ION ABUNDANCES IN SOLAR FLARE ENERGETIC PARTICLE EVENTS

G. M MASON, H. WEISS, G GLOECKLER (Maryland, University, College Park, MD), and D. HOVESTADT (Max-Planck-Institut fuer Physik und Astrophysik, Garching, West Germany) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 124-127 refs (Contract NAS5-11063; NAS5-25735; NGR-21-002-316)

Data from a survey of solar flare events undertaken by the UMD/MPI ULET telescope on the IMP-8 satellite during the period 1973-1977 yields examples of time and energy dependence of the abundances and spectra of the He, C, O and Fe heavy ions. Time variations are found in the O/He, O/C and Fe/O ratios which appear to be inconsistent with models based entirely on rigidity-dependent propagation in the interplanetary medium. It is speculated that such other factors as the abundance differences at the flare site on the sun, or features of the acceleration and release mechanisms, may play an important role in the variations discussed.

A82-22606* California Inst of Tech., Pasadena. HIGH RESOLUTION MEASUREMENTS OF SOLAR FLARE ISOTOPES

R. A. MEWALDT, J. D. SPALDING, E. C. STONE, and R. E. VOGT (California Institute of Technology, Pasadena, CA) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 131-134. refs (Contract NAS5-20721; NGR-05-002-160)

The individual isotopes of C, N and O are measured in the large solar particle event of August 1978 Limits are placed on mass dependent selection effects occurring in the solar flare by fitting a simple mass fractionation law to measurements of the C, N, O and Mg isotopes, to relate the SEP composition more directly to the composition of the sun. The individual isotopes are found to be consistent with solar system abundances, and the absence of any observable fractionation for C, O and Mg leads to the conclusion that solar neon is most likely neon-A with Ne-22/Ne-20 equals 0 12.

A82-22616

11-YEAR MODULATION AND SPECTRUM OF COSMIC RAYS IN THE INTERSTELLAR SPACE

A. G ZUSMANOVICH (Akademia Nauk Kazakhskoi SSR, Sektor lonosfery, Alma-Ata, Kazakh SSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 183-186 refs

The 11-year modulation in cosmic ray intensity is examined with a view towards the study of cosmic ray spectra in interstellar space. The steady-state, homogeneous solution of the cosmic ray modulation equation is used to determine a value of 0.4 plus or minus 0.1 for the modulation coefficient and a value between 15 and 20 GV for the rigidity of the unmodulated spectrum. Cosmic ray spectra outside the modulation region are then calculated from the modulation coefficient and differential energy spectra measured near earth at solar activity minimum, taking into account cosmic ray energy changes during passage through interplanetary space. Results are shown to be in agreement with measurements of galactic gamma ray intensities A.L.W.

DETECTION OF ENVIRONMENTAL DISTURBANCE USING COLOR AERIAL PHOTOGRAPHY AND THERMAL INFRARED IMAGERY

S. ARONOFF and G A. ROSS (Calgary, University, Calgary, Alberta, Canada) Photogrammetric Engineering and Remote Sensing, vol 48, Apr 1982, p. 587-591. Research supported by the Alberta Oil Sands Environmental Research Program. refs

Characteristics of a program for satellite remote sensing for long-period environmental monitoring are examined, noting that establishing early mapping surveys of areas of concern aids in detection of stressful environmental conditions. The process is described with an example from IR and color photography of a 30,000 sq km area in the Athabasca Oil Sands, with the photography carried out from aircraft and satellite. The IR data was gathered between 8-14 microns and the photographs were taken at a 1:11,000 scale. Water-related disturbances detected included turbidity which indicated the possible presence of oil, and higher thermal emission near a tailings pond which also suggested an oil source. The presence of surface aquatic vegetation is an indicator of nutrient imbalance in a pond near a sewage pond. Finally, dead trees were observed near improperly installed culverts along new roads. MSK

A82-29332* South Carolina Univ., Columbia. DETECTING RESIDENTIAL LAND-USE DEVELOPMENT AT THE URBAN FRINGE

J. R. JENSEN (South Carolina, University, Columbia, SC) and D. L. TOLL (NASA, Goddard Space Flight Center, Greenbelt, MD) Photogrammetric Engineering and Remote Sensing, vol. 48, Apr. 1982, p 629-643. refs

Problems associated with the use of Landsat multispectral scanner (MSS) imagery for the detection of urban growth and land use patterns are discussed. The presence of vegetation, either original or added between scanning periods, has been found to dramatically effect the range of signatures in a given area. Different land use developmental stages have been successfully identified by means of 1:50,000 scale panchromatic aerial photography, a resolution only considered possible by spaceborne instrumentation with the advent of the Landsat D satellite. Textural information generated through the grey-tone spatial-dependency matrix for the Landsat band 5 data is compared for different years and a change detection algorithm is described. It is found that the addition of vegetation during development after the removal of natural vegetation resulted in error of omission in the single band data, which must therefore only be used in concert with other data sources. M.S.K.

A82-30293 AIRCRAFT MONITORING OF SURFACE CARBON DIOXIDE EXCHANGE

R L. DESJARDINS, E. J BRACH (Agriculture Canada, Ottawa, Canada), P. ALVO, and P. H SCHUEPP (McGill University, Sainte Anne de Bellevue, Quebec, Canada) Science, vol. 216, May 14, 1982, p. 733-735 Research supported by Agriculture Canada and National Research Council. refs

Aircraft-mounted sensors were used to measure the exchange of carbon dioxide above a cornfield, a forest, and a lake under midday conditions Mean absorption values of 3400, 1200, and 100 milligrams of carbon dioxide per square meter per hour, respectively, are consistent with reported ground-based observations of carbon dioxide flux. Such information, gathered by aircraft, could be used to provide a quantitative evaluation of source and sink distributions of carbon dioxide in the biosphere, to establish a correlation between satellite data and near-surface measurements, and to monitor crop performance (Author)

PROBLEMS OF THE INTERPRETATION OF AERIAL AND SATELLITE IMAGES OF INDUSTRIAL SMOKE [PROBLEMY INTERPRETACJI LOTNICZYCH I SATELITARNYCH ZDJEC DYMOW PRZEMYSLOWYCH]

T. Z. DWORAK (Instytut Meteorologii) Gospodarki Wodnej, Krakow, Poland) Przeglad Geofizyczny, vol 25, no. 1, 1980, p 33-38. In Polish refs

Methods for the interpretation of aerial and satellite photographs of industrial smoke emissions are considered, with particular attention given to the difficulties of the qualitative interpretation of such images. Conditions that should be taken into account in an approximate solution of the radiative-transfer equations are examined. Recommendations on the practical solution of a specific satellite remote-sensing problem are presented BJ

A82-31295#

DETECTION OF VOLCANIC SMOKE AND ASH-FALL AREA AT VOLCANO ASO, FROM LANDSAT MSS DATA

Y TANAKA (Meteorological Research Institute, Isukuba, Ibaraki, Japan), K. TSUCHIYA, and Y YAMAURA (National Space Development Agency of Japan, Tokyo, Japan) Papers in Meteorology and Geophysics, vol 32, Dec 1981, p. 275-290. refs

Landsat imagery is employed to determine the extent of volcanic smoke and ashfall associated with the eruptions of the volcano ASO in 1979 and 1980, and a comparison is made with nearby meteorological data. Pictures from four bands 0.5-0.6, 0.6-0.7, 0.7-0.8, and 0.8-1.1 micron, are analyzed for information on volcanic smoke, polluted sea water, vegetation, clouds, and visibility over urban areas The imagery comprises natural, false, and Ektachrome colors, taken from multispectral band scanners on Landsats 2 and 3 A qualitative analysis of volcanic smoke is developed, and a comparison of topographic data with the Landsat images showed that the Landsat pictures are useful and sufficiently accurate for detecting terrain changes due to the volcanic activity, including the forms of caldera. Assessment of the volcanic state, smoke, and ashfall were also possible using the Landsat imagery.

SYSTEM ALBEDÓ AS SENSED BY SATELLITES - ITS DEFINITION AND VARIABILITY

N A HUGHES (Liverpool, University, Liverpool, England) and A HENDERSON-SELLERS (NASA, Goddard Institute for Space Studies, New York, NY; Liverpool, University, Liverpool, England) International Journal of Remote Sensing, vol. 3, Jan.-Mar. 1982, p. 1-11 Natural Environment Research Council refs

(Contract NERC-GR3/3941)

System albedo, an important climatological and environmental parameter, is considered. Some of the problems and assumptions involved in evaluating albedo from satellite data are discussed. Clear-sky and cloud albedos over the United Kingdom and parts of northwest Europe are treated Consideration is given to the spectral, temporal, and spatial variations and the effect of averaging The implications of these results for those using and archiving albedo values and for future monitoring of system albedo are discussed Normalization is of especial importance since this correction alters many albedo values. The pronounced difference in spectral albedo of the two visible channels reemphasizes the problem of attempting to calculate integrated albedo values from meteorological satellite data The assumption of isotropic reflection is seen to be invalid, hindering the computation of accurate albedo values CR

A82-32348* Alabama Univ , Huntsville

REMOTE SENSING OF TORNADIC STORMS FROM GEOSYNCHRONOUS SATELLITE INFRARED DIGITAL DATA R. J HUNG (Alabama, University, Huntsville, AL) and R. E. SMITH (NASA, Marshall Space Flight Center, Huntsville, AL) International Journal of Remote Sensing, vol. 3, Jan -Mar 1982, p. 69-81 refs

(Contract NAS8-33726)

Two cases of GOES digital infrared data were analyzed during the three-hour period immediately prior to the tornado touchdown times. Clouds associated with tornadoes were compared to those without tornadoes using a combination of satellite infrared and rawinsonde data On the basis of this limited data sample, it appears as if the altitude to which the overshooting cloud top penetrated above the tropopause is the factor which determines whether or not a tornado is formed. In these cases, the overshooting cloud top collapsed about 15 to 30 min before the tornado touchdown.

RESOURCE INVENTORY TECHNIQUES USED IN THE CALIFORNIA DESERT CONSERVATION AREA

R G. MCLEOD (California Institute of Technology, Jet Propulsion Laboratory Image Processing Laboratory, Pasadena, CA) and H. B. JOHNSON (U.S. Department of Agriculture, Grassland Soil and Water Research Laboratory, Temple, TX) In: Imaging spectroscopy; Proceedings of the Seminar, Los Angeles, CA, February 10, 11, 1981. Bellingham, WA, SPIE - The International Society for Optical Engineering, 1981, p 2-16. refs (Contract NAS7-100)

A variety of conventional and remotely sensed data for the 25 million acre California Desert Conservation Area (CDCA) have been integrated and analyzed to estimate range carrying capacity Multispectral classification was performed on a digital mosaic of ten Landsat frames. Multispectral classes were correlated with low level aerial photography, quantified and aggregated by grazing allotment, land ownership, and slope. (Author)

SAMPLE DESIGN FOR ESTIMATING CHANGE IN LAND USE AND LAND COVER

G. H. ROSENFIELD (U.S. Geological Survey, Reston, VA) Photogrammetric Engineering and Remote Sensing, vol. 48, May 1982, p. 793-801. refs

The tasks of the field of applied statistics known as sample design are enumerated as: (1) sampling within a specified population, (2) consideration of sampling distribution; (3) determination of sample size; (4) determination of sample selection procedure; and (5) estimation of population means, totals, variances and confidence limits from the sample information. This methodology, which is used in the estimation of land use and land cover change, is sufficiently general to extend to the determination of change in any type of time-variant thematic mapping. An opportunity is presented for the determination of land use and land cover change in the state of Pennsylvania over a 20-year period.

A82-32899

IMPACTS OF REMOTE SENSING ON U.S. GEOGRAPHY

J. E ESTES, D. S. SIMONETT (California, University, Santa Barbara, CA), and J R JENSEN (Georgia, University, Athens, GA) Remote Sensing of Environment, vol. 10, Aug. 1980, p. 43-80. refs

Attention is called to the fact that few senior academic geographers are doing research in remote sensing and that few economic geographers have even considered the possibilities opened up by this technique. This dearth of research is even more pronounced among regional geographers with interests in less-developed countries Programs of study in remote sensing are considered vital because remote sensing can provide the geographer with significant improvements in the quantity, quality, and timeliness of data.

A82-32901

EFFECT OF ATMOSPHERIC CONDITIONS ON REMOTE SENSING OF VEGETATION PARAMETERS

J V. DAVE (IBM Scientific Center, Palo Alto, CA) Remote Sensing of Environment, vol 10, Sept. 1980, p. 87-99. refs

The effects of atmospheric and observational conditions on the remote sensing of vegetation parameters are studied in simulations of the ratios of radiances in the 0 76-0 90 micron and 0.52-0.60 micron bands (Landsat Thematic Mapper bands 4 and 2, respectively) as a function of leaf water content in blue grama grass. The simulations were performed based on spectral flux reflectance and canopy data for 35 plots with different leaf water levels and three different models of the cloud-free midlatitude summer atmosphere with no, moderate and high aerosol contents at solar zenith angles from 0 to 80 deg, heights from the top to the bottom of the atmosphere, nadir angles from 0 to 75 deg and azimuth angles from 0 to 180 deg. Selected results demonstrate that the slope and intercept of the straight line expressing the dependence of radiance ratio on leaf water content can be significantly affected by atmospheric conditions and viewing geometry. SOUFRIERE VOLCANO, ST. VINCENT - OBSERVATIONS OF ITS 1979 ERUPTION FROM THE GROUND, AIRCRAFT, AND SATELLITES

R. S. FISKE (Smithsonian Institution, Washington, DC) and H. SIGURDSSON (Rhode Island, University, Kingston, RI) Science, vol. 216, June 4, 1982, p. 1105, 1106. refs

The 1979 eruption of Soufriere Volcano, St Vincent, is described. The initial vulcanian explosive phase from April 13 to 26 was a series of discrete vertical explosions, blasting a new vent through the 1971-1972 lava island in the middle of the 1-km-wide crater lake. The second phase was characterized by the quiet extrusion of viscous basaltic andesite lava, resulting in the growth of a dome over the vent. The importance of the geologic, seismic and ground-deformation data gathered prior to the eruption is discussed. D.L.G

GEOSTATIONARY SATELLITE OBSERVATIONS OF THE APRIL 1979 SOUFRIERE ERUPTIONS

A. F KRUEGER (NOAA, National Weather Service, Washington, DC) Science, vol. 216, June 4, 1982, p 1108, 1109. refs

Infrared images from the geostationary satellite SMS-1 were used to study the growth of the eight major eruptions of Soufriere, St. Vincent, during April, 1979 These eruptions differed considerably in growth and intensity, the most intense being that of April 17, which formed an ash cloud of 96,000 square kilometers in 4 hours The weakest eruption formed a cloud of only 16,000 square kilometers. (Author)

A82-33655

METEOROLOGICAL ANALYSIS OF THE ERUPTION OF SOUFRIERE IN APRIL 1979

S. BARR (Los Alamos National Laboratory, Los Alamos, NM) and J. L HEFFTER (NOAA, Air Resources Laboratory, Silver Spring, MD) Science, vol 216, June 4, 1982, p. 1109-1111. refs

Meteorological upper-air data, in conjunction with satellite imagery, lidar light detection and ranging returns, and aircraft sampling, aid in the determination of plume altitude and transport. The estimated trajectories indicate that the ash was transported eastward across the Atlantic to Africa in 3 to 5 days and that there was modest meridional transport as far as 15 deg poleward during the first week of travel. SKIRT CLOUDS ASSOCIATED WITH THE SOUFRIERE ERUPTION OF 17 APRIL 1979

S. BARR (Los Alamos National Laboratory, Los Alamos, NM) Science, vol 216, June 4, 1982, p. 1111, 1112.

A fortuitous and dramatic photograph of the Soufriere eruption column of April 17, 1979 displays a series of highly structured skirt clouds. The gentle distortion of thin, quasi-horizontal layers of moist air has been documented in meteorological situations. It is proposed that at St. Vincent subhorizontal layers of moist air were intensely deformed by the rapidly rising eruption column and were carried to higher altitudes, where they condensed to form the skirt clouds (Author)

AIRBORNE LIDAR MEASUREMENTS OF THE SOUFRIERE ERUPTION OF 17 APRIL 1979

 W. H. FULLER, JR, S SOKOL (NASA, Langley Research Center, Hampton, VA), and W. H HUNT (Wyle Laboratories, Hampton, VA) Science, vol 216, June 4, 1982, p. 1113-1115 refs At the time of the Soufriere, St. Vincent, volcanic eruption of

At the time of the Soufriere, St. Vincent, volcanic eruption of April 17, 1979, a NASA P-3 aircraft with an uplooking lidar (light detection and ranging) system onboard was airborne 130 kilometers east of the island. Lidar measurements of the fresh volcanic ash were made approximately 2 hours after the eruption, 120 kilometers to the northeast and east. On the evening of April 18, the airborne lidar, on a southerly flight track, detected significant amounts of stratospheric material in layers at 16, 17, 18, and 195 kilometers. These data, and measurements to the north on April 19, indicate that the volcanic plume penetrated the stratosphere to an altitude of about 20 kilometers and moved south during the first 48 hours after the eruption. FINE PARTICLES IN THE SOUFRIERE ERUPTION PLUME

D C. WOODS (NASA, Langley Research Center, Hampton, VA) and R L CHUAN (Brunswick Corp., Costa Mesa, CA) Science, vol. 216, June 4, 1982, p. 1118, 1119. refs

The size distributions of fine particles measured at tropospheric altitudes in the periphery of the eruption plume formed during the April 17, 1979 eruption of Soufriere Volcano and in the low-level effluents on May 15, 1979 were found to be bimodal, having peak concentrations at geometric mean diameters of 1.1 and 0.23 micrometers. Scanning electron microscopy and energy-dispersive X-ray analysis of the samples revealed an abundance of aluminum and silicon and traces of sodium, magnesium, chlorine, potassium, calcium, and iron in the large-particle mode The submicrometer-sized particles were covered with liquid containing sulfur, assumed to be in the form of liquid sulfuric acid. EPA'S NEW BUBBLE AND BANKING POLICIES

M. R. DELAND (U.S. Environmental Protection Agency, Environmental Monitoring Systems Laboratory, Las Vegas, NV) Environmental Science and Technology, vol. 16, June 1982, p. 338A-346A refs

The uses of multispectral scanning (MSS), laser technology, and aerial photography in remote sensing programs to monitor potential and existing environmental problems are examined. Airborne MSS applications involve the detection of visible and IR emissions from the earth's surface for electronic cleaning of the imagery and reproduction of the sensed scene. Spectroscopic coding of the images allows identification of pollutants, the health of vegetative cover, and the state of observable water quality Airborne laser sensing of chlorophyll-a in water bodies has allowed association of dissolved organic nutrients, due mainly to sewage discharges, with increases in the population of the algae Lidar measurements permit digitized air quality measurements from aircraft. The development of a differential absorption lidar (DIAL) system, using two lasers close in frequency output, is paving the way for specific species labeling MSK.

THE USE OF LANDSAT-3 THERMAL DATA TO HELP DIFFERENTIATE LAND COVERS

J. P. ORMSBY (NASA, Goddard Space Flight Center, Earth Survey Applications Div., Greenbelt, MD) Remote Sensing of Environment, vol. 12, May 1982, p. 97-105. refs

Landsat-3 Multispectral Scanner Subsystem (MSS) digital data of the Baltimore, Maryland area gathered on May 24, 1978, are examined to show the usefulness of thermal data in providing better discrimination between agricultural and residential areas, certain types of urban/industrial areas and water, cloud shadows and water, and bare-extractive areas and bright urban cover types High altitude aircraft imagery taken on May 3, 1978, provides ground truth and training site verification. Two classifications are made for each training site the initial one using bands 4, 5, and 7 and a second in which the thermal data are included with the visible and near infrared data. This permits a direct comparison of areas spectrally similar with and without the inclusion of the thermal data. Commission errors determined from selected subsets of the data show reductions of 95% for the urban/industrial versus water themes, 84% for the residential versus agriculture themes, 64.0% for the bare-extractive versus bright urban themes, and 24% for the cloud shadow versus water themes when the thermal data are included in the signature

SITE SELECTION AND ENGINEERING ISSUES FOR A MAJOR INDUSTRIAL COMPLEX - APPLICATION OF IMAGE AND MAP INTERPRETATION

D. S WAY (Harvard University, Cambridge, MA) In American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p 164-169

A major port and industrial complex is being developed in Indonesia near Singapore. Little existing data is available facilitating application of remote sensing techniques for site evaluation and planning. Over eight hundred square kilometers of area was analyzed. Landsat images, aerial photographs, and topographic maps where interpreted for geology, geomorphology, soils, hydrology, and visual resources Evaluations were made for both environmental and development/engineering issues culminating in a phased master plan The data contributed by remote sensing represented a significant savings in site reconnaissance, design and construction. (Author) A82-34739

A NEW APPROACH TO MULTIRESOURCE INVENTORIES USING REMOTE SENSING AND GEOGRAPHIC INFORMATION SYSTEMS TECHNOLOGIES

J. VAN ROESSEL, P. G. LANGLEY, C. SHEFFIELD, and M. C PLACE (Earth Satellite Corp, Berkeley, CA) In American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p. 499-510. refs

The design for a new multiresource inventory system is presented Two geographic information systems are employed in concert to support a sampling system which can provide estimates for multiple resource parameters One GIS (the upper level) is cell- and tape- oriented and incorporates various types of Landsat processing The other (the lower level) is a disk-based polygon system that holds high resolution sample maps The two systems are connected through a linear regression model. The results of a pilot test of a prototype system in South Carolina are presented.

IMPROVED LAND USE CLASSIFICATION FROM LANDSAT AND SEASAT SATELLITE IMAGERY REGISTERED TO A COMMON MAP BASE

J. CLARK (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA) In American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p 591-599. refs

(Contract NAS7-100)

In the case of Landsat Multispectral Scanner System (MSS) data, ambiguities in spectral signature can arise in urban areas. A study was initiated in the belief that Seasat digital SAR could help provide the spectral separability needed for a more accurate urban land use classification. A description is presented of the results of land use classifications performed on Landsat and preprocessed Seasat imagery that were registered to a common map base. The process of registering imagery and training site boundary coordinates to a common map has been reported by Clark (1980). It is found that preprocessed Seasat imagery provides signatures for urban land uses which are spectrally separable from Landsat signatures This development appears to significantly improve land use classifications in an urban setting for class 12 (Commercial and Services), class 13 (Industrial), and class 14 (Transportation, Communications, and Utilities) GR

LONGWAVE INFRARED OBSERVATION OF URBAN LANDSCAPES

S N. GOWARD (NASA, Goddard Institute for Space Studies; Columbia University, New York, NY) In American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p 600-609. Research supported by the Indiana Academy of Science and Indiana State University. refs

An investigation is conducted regarding the feasibility to develop improved methods for the identification and analysis of urban landscapes on the basis of a utilization of longwave infrared observations. Attention is given to landscape thermal behavior, urban thermal properties, modeled thermal behavior of pavements and buildings, and observed urban landscape thermal emissions. The differential thermal behavior of buildings, pavements, and natural areas within urban landscapes is found to suggest that integrated multispectral solar radiant reflectance and terrestrial radiant emissions data will significantly increase potentials for analyzing urban landscapes. In particular, daytime satellite observations of the considered type should permit better identification of urban areas and an analysis of the density of buildings and pavements within urban areas. This capability should enhance the utility of satellite remote sensor data in urban applications. G.R.

OBSERVED MAGNETIC SUBSTORM SIGNATURES AT SYNCHRONOUS ALTITUDE

T. NAGAI Journal of Geophysical Research, vol. 87, June 1, 1982, p. 4405-4417. refs

Magnetic field data from the geostationary satellites GOES 2 and GOES 3 are examined to study the development of substorm activity in the near-earth nightside magnetosphere (around a radial distance of 6.6 earth radii). Substorm events are those in which a well-defined single onset is seen at low latitudes on the ground. The field configuration change from more taillike to more dipolelike starts initially in a longitudinally localized region in association with the ground onset, and it develops westward and eastward, even when the simultaneous onset of the low-latitude positive bay is recorded in a wide longitudinal region on the ground. It is also found that the variation caused by the field-aligned current starts at the ground onset and reaches a peak at the time of the field change. The present results are consistent with the view that a substorm is associated with a disruption and subsequent conversion of the cross-tail current to the field-aligned current connected with the polar ionosphere. It is indicated that the cross-tail current near synchronous orbit and its disruption are important in producing the field configuration change at synchronous orbit (Author)

A82-35542* Maryland Univ , College Park GENERATION OF THE AURORAL KILOMETRIC RADIATION C. S. WU, H. K. WONG (Maryland, University, College Park, MD), D. J GORNEY (Aerospace Corp , Space Sciences Laboratory, El Segundo, CA), and L C. LEE (Alaska, University, Fairbanks, AK) Journal of Geophysical Research, vol. 87, June 1, 1982, p. 4476-4487. refs

(Contract F04701-80-C-0081; NSF ATM-81-16045; NGL-21-002-005)

Data collected from the S3-3 spacecraft in the auroral kilometric radiation (AKR) source region are employed to form a stability theory from which numerical results are obtained and discussed. The distribution function was found to be isotropic outside the auroral atmospheric loss-cone region, which was partially filled with upcoming electrons A parallel electric field was observed to be modifying the loss-cone distribution A model distribution function is formulated, along with a magnetic field model expressed in terms of the electron cyclotron frequency Models for the parallel electric field are also introduced, the first with the field distributed over a broad altitude range, while the second assumes a potential drop only above 4000 km. The presence of the field is found to enhance the growth rate of the AKR. At higher altitudes, the cutoff frequency of the X mode is affected by the rising energetic electrons. Finally, the folding distances of spatial amplification are calculated. M.S.K.

OBSERVATION OF THE DIURNAL VARIATION OF **ATMOSPHERIC OZONE**

J. L. LEAN (Adelaide, University, Adelaide, Australia) Journal of Geophysical Research, vol 87, June 20, 1982, p. 4973-4980. Research supported by the World Meteorological Organization. refs

Ozone densities in the stratosphere and mesosphere have been derived from broad-band photometer measurements of Hartley band absorption of middle ultraviolet radiation. Seven rockets were launched during October-November 1979 from Wallops Island. Six rockets, each carrying one detector comprising two UV photometers, were launched at different times of the day. A seventh rocket, with three similar detectors each having three UV photometers, was launched at the time of a full moon and provided estimates of the nighttime ozone densities. Results from these rocket flights form a basis for investigating ozone diurnal variations. The number of flights provide greater statistical reliability for the ozone profiles than is generally afforded from in situ measurements with a single rocket. During the night, an enhancement in ozone

densities occurred at altitudes above about 50 km At 70 km, for example, the nighttime ozone was determined to be a factor of 6.4 greater than at sunset. In addition, these experiments suggest that near 40 km the magnitude of the ozone density at noon may be greater by 10-15% than the nighttime concentration (Author)

TOTAL OZONE VARIATIONS 1970-74 USING BACKSCATTERED ULTRAVIOLET /BUV/ AND GROUND-BASED OBSERVATIONS A J MILLER, R. M. NAGATANI, T G. ROGERS (NOAA, National Meteorological Center, Washington, DC), A. J. FLEIG, and D F HEATH (NASA, Goddard Space Flight Center, Greenbelt, MD) Journal of Applied Meteorology, vol 21, May 1982, p. 621-630. NASA-supported research. refs

The most long-lived satellite set of ozone observations, to date, is that derived from the Backscatter Ultraviolet (BUV) ozone sensor on Nimbus 4 and extends from April 1970 through 1976. Unfortunately, this experiment suffered spacecraft power limitations which limited the spatial and temporal coverage and also appears to have suffered from long-term drifts which may be associated with changes in the instrument characteristics or the incident solar flux Techniques have been developed to account for these problems, and this paper presents results of the BUV total ozone variations and compares them with those from ground-based observations, specifically the computations of Angell and Korshover (1978). After adjustments for the spatial gaps and comparison with concurrent Dobson ground-based observations, no significant trend was found in the BUV data over the years 1970-74 This finding is in contrast to a general decrease of about 2% during the same period appearing in the data of Angell and Korshover. The difference in these results is discussed in terms of the geographic sampling and the methods of hemispheric integration (Author)

CHARACTERISTICS **E-REGION** OF **FIELD-ALIGNED** IRREGULARITIES OVER IIOKA /36 N/, JAPAN. I

T TANAKA and S. V. VENKATESWARAN (California, University, Los Angeles, CA) Journal of Atmospheric and Terrestrial Physics, vol. 44, May 1982, p. 381-393, 395-397, 399-406 refs (Contract NSF ATM-77-24843)

Measurements with a 25-MHz radar over lioka, Japan, reveal that field-aligned E-region irregularities occur mainly at night in association with sporadic E (Es) layers at an altitude range of about 100-110 km and that they drift predominantly westward with speeds of the order of 60 m/s. It is shown that these observed characteristics of the irregularities are in reasonable agreement with quantitative predictions of the gradient drift instability theory. The predictions are based on appropriate models for neutral air densities and temperatures, ionic composition and ionospheric electric field, and available observations of electron density profiles of the E and Es lavers. Observations of multifrequency (4-64 MHz) echoes with an oblique incidence ionosonde and of Doppler spectra with a fixed frequency (25 MHz) radar are then presented and discussed. It is shown that the ionosonde observations are capable of being explained in terms of the linear theory of cross-field or

gradient-drift instability, which is presumed to generate the field-aligned irregularities C.R

AMMONIA AND THE NOX BUDGET OF THE TROPOSPHERE J. S LEVINE, T. R. AUGUSTSSON, and J. M. HOELL (NASA, Langley Research Center, Hampton, VA) American Meteorological Society, American Geophysical Union, and NASA, Symposium on

the Composition of the Nonurban Troposphere, 2nd, Williamsburg, VA, May 25-28, 1982, Paper. 3 p. refs

Liu et al (1980) suggested that NOx transported from the stratosphere, as opposed to the anthropogenic source of NOx, may be the dominant source that controls the distribution of NOx in the global troposphere. These ideas require a reinvestigation, and, in particular, an assessment of the role of the oxidation of ammonia as a source of NOx. Attention is given to the results of an ammonia measurement program, in which the vertical distribution of ammonia in the troposphere and lower stratosphere could be studied with the aid of the infrared Heterodyne Radiometer (IHR). a solar-viewing remote sensor. A one-dimensional photochemical model of the troposphere reported by Levine et al. (1980) was employed to study the chemical and physical processes that control the loss of ammonia in the troposphere. The results of the considered investigation suggest that the oxidation of ammonia may indeed be a significant source of NOx in the troposphere G.R.

ATMOSPHERIC OZONE DETERMINATION BY SOLAR OCCULTATION USING THE UV SPECTROMETER ON THE SOLAR MAXIMUM MISSION

A. C. AIKIN, B. WOODGATE (NASA, Goddard Space Flight Center, Greenbelt, MD), and H. J. P SMITH (Visidyne, Inc., Burlington, MA) Applied Optics, vol. 21, July 1, 1982, p. 2421-2424. refs

The UV spectrometer polarimeter instrument on the Solar Maximum Mission spacecraft has been used to measure ozone in the 53-75 km altitude interval by the technique of solar occultation A 1 x 180 arcsec entrance aperture spectrometer with 0.04-A spectral resolution was employed. Resulting high-quality data are reduced by expressing measured UV attenuation as a Volterra integral equation. Solution of the equation is accomplished by expressing the integral in terms of a series representing the sum of ozone densities contained in concentric shells through tangent points separated by specified altitude increments Sample ozone vs altitude profiles are presented for the equatorial region. These data show reproducibility to better than 10%. The density at 60

km is 7.3 + or - 0 15 x 10 to the 9th/cu cm for 2.5 deg latitude and longitudes between 81 and 105 deg west in September 1980 Density vs altitude profile exhibits changes in slope between 50 and 75 km (Author)

SENSITIVITY OF DOBSON TOTAL OZONE ESTIMATIONS TO WAVELENGTH BAND CALIBRATION UNCERTAINTIES

R E. BASHER (New Zealand Meteorological Service, Wellington, New Zealand) In: Quadrennial International Ozone Symposium, Boulder, CO, August 4-9, 1980, Proceedings. Volume 1. Boulder, CO, International Association of Meteorology and Atmospheric Physics, 1981, p 33-36 refs

It is pointed out that calibration uncertainties in the center wavelength, bandwidth, and shape of the Dobson instrument's bands propagate uncertainty into extraterrestrial constants, ozone absorption coefficients, standard lamp calibrations, and total ozone estimations. Detailed calculations of these uncertainties have been conducted for a wide range of conditions of calibration and operation it is emphasized that all of the considered calculations refer to the defined 'well calibrated', 'well operated' instrument. It is found that the percent standard errors in total ozone are very dependent on airmass and ozone amount. The errors are greatest at low airmass and low ozone, especially for the D and CD band combinations. The AD combination generally has the least error of the double wavelength pairs, and for the directly intercompared instruments has a standard error of 1 1% or less G.R

A82-36406#

THE EFFECT OF THE SPECTRAL ATTENUATION OF UV RADIATION BY AEROSOL ON THE TOTAL OZONE MEASUREMENTS

A. DZIEWULSKA-LOSIOWA (Polska Akademia Nauk, Instytut Geofizyki, Warsaw, Poland) In: Quadrennial International Ozone Symposium, Boulder, CO, August 4-9, 1980, Proceedings Volume 1. Boulder, CO, International Association of Meteorology and Atmospheric Physics, 1981, p. 38-45. US Environmental Protection Agency refs

(Contract EPA-5-536-4)

The effect of aerosol in the atmosphere on ozone measurements is considered. Shah (1976) had concluded that changes in aerosol concentration and particle size distribution affect the measurement results only slightly. DeLuisi (1975), on the other hand, had found that substantial differences exist between values for ozone content obtained by taking into account scattering, and values calculated without regard to scattering effects. Instrumental errors are analyzed and the statistical relationship between measurements at different wavelengths are investigated. It is found that different wavelength pairs are greater than instrumental errors. It is shown that these results are connected with the spectral extinction of the atmospheric aerosol G.R

APPLICATION OF INFRARED TECHNIQUES TO THE STUDY OF ATMOSPHERIC OZONE [APPLICATION DES TECHNIQUES INFRAROUGES A L'ETUDE DE L'OZONE ATMOSPHERIQUE]

C SECROUN, A. BARBE, P MARCHE, and P JOUVE (Reims, Universite, Reims, France) In: Quadrennial International Ozone Symposium, Boulder, CO, August 4-9, 1980, Proceedings. Volume 1. Boulder, CO, International Association of Meteorology and Atmospheric Physics, 1981, p. 108-113 In French. refs

The present investigation is concerned with the utilization of the infrared wavelength region for the study of the ozone in the atmosphere, taking into account three atmospheric windows including the wavelength ranges near 10, 5, and 3 micrometers. More than 3200 spectral lines could be assigned to different bands of the ozone spectrum Laboratory studies formed one part of the investigation Spectral frequencies, absorption line intensities, and linewidths were determined for ozone. Some of the obtained results were employed in connection with data provided by the radiometric probe LIMS on board the Nimbus-7 satellite. The second part of the investigation involved a study of the atmosphere. The same spectrometer as in the laboratory study was utilized, and the sun was employed as radiation source. The obtained results were compared with data provided by a Dobson spectrophotometer Attention is also given to vertical concentration profiles. It is concluded that infrared absorption spectroscopy represents a suitable technique for studies of atmospheric ozone. G R

MICROWAVE MEASUREMENT OF STRATOSPHERIC AND MESOSPHERIC OZONE

J W. WATERS (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA) In: Quadrennial International Ozone Symposium, Boulder, CO, August 4-9, 1980, Proceedings. Volume 1. Boulder, CO, International Association of Meteorology and Atmospheric Physics, 1981, p. 114-121. refs

It is pointed out that ozone has a rich rotational spectrum with many lines at millimeter wavelengths Measurement of these lines can provide a means of remotely sensing stratospheric and mesospheric ozone. Technology has recently advanced to the state where it is reasonable to consider monitoring upper atmospheric O3 on a global scale by microwave radiometers in earth orbit An investigation indicates that approximately 1% accuracy and approximately 2 km vertical resolution O3 mixing ratio measurements are reasonable goals for limb-viewing microwave radiometers in earth orbit. Mesospheric ozone can also be measured by the considered techniques using stronger (but more temperature-sensitive) O3 lines. A balloon-borne microwave limb sounder has recently been constructed to test the practical limitations on the measurement concepts. Also under study is a microwave limb sounder for operation in earth orbit. G R

TOTAL OZONE RETRIEVAL FROM SATELLITE METEOR 28 FOURIER SPECTROMETER MEASUREMENTS

U FEISTER and D SPAENKUCH (Meteorologisches Hauptobservatorium, Potsdam, East Germany) In: Quadrennial International Ozone Symposium, Boulder, CO, August 4-9, 1980, Proceedings. Volume 1 Boulder, CO, International Association of Meteorology and Atmospheric Physics, 1981, p 168-175. refs

The efficiency and accuracy of four different algorithms for deriving total ozone from IR radiance measurements made with Fourier spectrometers are assessed. For a total of more than 1.100 spectrometer-interferometer spectra measured between July and September 1977, 40 corresponding Dobson ozone values are found with a maximum spatial distance between the subsatellite point and the Dobson station of 300 km and an average distance of 175 km; 35 values here are from midlatitudes of the Northern Hemisphere. The Dobson ozone values are used in determining a different number of coefficients for each method applying the least square method With these coefficients, ozone values are calculated. The original number of spectral channels is then reduced to two intervals. It is found that a radiometer with one or two channels in the 96/micron band in the window and in the 15/micron band is sufficient for the total ozone determination A highly significant positive correlation is found between spectrometer-interferometer ozone and calculated relative topographies of the lower stratosphere. This correlation holds even if the latitudinal dependence and autocorrelation of ozone values and relative topographies are eliminated. C.R.

A82-36428#

OPTICAL STOP AND FOCUSSING EFFECTS IN THE DOBSON INSTRUMENT

R. E. BASHER (New Zealand Meteorological Service, Wellington, New Zealand) In Quadrennial International Ozone Symposium, Boulder, CO, August 4-9, 1980, Proceedings. Volume 1 Boulder, CO, International Association of Meteorology and Atmospheric Physics, 1981, p. 216-218

The present investigation shows that the 'directional effect' observed in connection with the photoelectric spectrometer designed by Dobson (1931) is caused by defects in optical stopping and focusing The considered effect consists of two parts, related to different field-of-view boundaries for the two wavelength bands being measured, and varying relative sensitivity across the field of view for the two bands. The stop problem is readily tested for and corrected, and it may affect only a limited number of instruments. The focussing problem, however, affects all but the earliest instruments, and its solution will require a careful consideration of the involved aspects.

ROBLE (National Center for Atmospheric Research, Boulder, CO) In: Quadrennial International Ozone Symposium, Boulder, CO, August 4-9, 1980, Proceedings Volume 1. Boulder, CO, International Association of Meteorology and Atmospheric Physics, 1981, p 572-579 refs

Solar occultation data gathered by the French ultraviolet spectrophotometer telescope on the NASA Orbiting Solar Observatory, scanning between about 50 deg N and 50 deg S between June 1975 and June 1976, are presented. The occultation profiles, observed near 2800 A, contain information on the ozone concentration at altitudes between about 52 and 75 km. Results obtained between June 5 and August 4, 1975 are discussed, longitudinal and latitudinal variations are demonstrated, and comparisons with published ozone density profiles are shown.

THE SEASONAL VARIATIONS OF OZONE AND TEMPERATURE IN THE MIDDLE AND THE UPPER STRATOSPHERE

S. CHANDRA (NASA, Goddard Space Flight Center, Laboratory for Planetary Atmospheres, Greenbelt, MD) In. Quadrennial International Ozone Symposium, Boulder, CO, August 4-9, 1980, Proceedings. Volume 2 Boulder, CO, International Association of Meteorology and Atmospheric Physics, 1981, p. 1083-1090 refs

The seasonal variations in ozone and temperature inferred from the Nimbus-4 BUV (Backscatter Ultraviolet Spectrometer) and the SCR (Selective Chopper Radiometer) experiments are compared with predictions based on a simplified radiative photochemical model. It is shown that the observations, in agreement with the model calculations, show a systematic phase shift from a summer maximum at 10 mb to a winter maximum at 1 mb with equinoctial maxima at intermediate heights. In contrast, the temperature between these pressure levels shows no appreciable phase shift and the summer maximum prevails at all heights. The observed phase differences in ozone and temperature are shown to be a manifestation of the radiative feedback on the photochemistry of the upper stratosphere (Author)

ON THE APPLICATION OF A MODEL OF BOUNDARY-LAYER FLOW OVER LOW HILLS TO REAL TERRAIN

J L WALMSLEY, J. R SALMON, and P. A. TAYLOR (Department of the Environment, Atmospheric Environment Service, Downsview, Ontario, Canada) Boundary-Layer Meteorology, vol 23, May 1982, p. 17-46 Research supported by the National Research Council of Canada. refs

Attempts to apply a computer model (Walmsley et al., 1980) to neutrally-stratified, boundary-layer flow over an isolated hill of moderate slope (Kettles Hill, Alberta) lead to velocity perturbation fields which probably overemphasize the impact of small-scale topographic features. Some numerical smoothing of the digitized terrain input field is found to be helpful in reducing this effect, although such a procedure is somewhat arbitrary. An extension of the original theory results in an improved representation of the effect of small-scale terrain components. These modifications are described and some results of an application of the extended model to Kettles Hill are presented (Author)

SOFT X-RAYS FROM THE SUNLIT EARTH'S ATMOSPHERE D L. MCKENZIE, H. R. RUGGE (Aerospace Corp., Space Sciences Laboratory, El Segundo, CA), and P. A. CHARLES (California, University, Berkeley, CA) Journal of Atmospheric and Terrestrial Physics, vol 44, June 1982, p 499-508. Research supported by

the Aerospace Corp refs (Contract NAS8-33235; NASW-3338; CIT-44-727600; NAS5-23315, F04701-79-C-0080)

Observations of soft X-ray emission from the sunlit earth atmosphere are presented and compared with the predictions of an earth albedo X-ray theory. The exact theory accounts for the flux of Thomson scattered solar X rays and fluorescently excited K X rays that arise following the absorption of incident X rays as a function of observing geometry Observations were made at widely separated geometries with the two low-energy detectors of the A-2 experiment on the HEAO-1 satellite Fitting of the model to the observed spectra results in values for the solar coronal temperature and emission measure that are in good agreement with expected values for the nonflaring sun, indicating that X-ray observations of the sunlit atmosphere may be a useful monitor of solar activity for satellites unable to view the sun directly. The total measured fluorescent line flux is also in agreement with calculations, although the N/O line ratio is not. X-ray fluorescence measurements from the sunlit atmosphere will thus be useful in monitoring atmospheric composition only to the extent that the total line counting rates depend upon the composition. RESOLUTION REQUIREMENTS FOR URBAN SPATIAL STUDIES

R. WELCH (Georgia, University, Athens, GA) International Journal of Remote Sensing, vol 3, Apr.-June 1982, p. 139-146. refs

Remote sensor data with spatial resolutions corresponding to 0 5-10 m IFOV are required to define adequately the high frequency detail which characterizes the urban scene. Effective analyses of the small parcels, compact structures and narrow street patterns typical of Asian environments will necessitate data of much higher resolution than are required for Western countries. Consequently it is unlikely that satellite image data expected for the 1980s will replace aerial photographs as a primary source of information about urban areas. (Author)

STREAMLINING AND ENSURING MINERAL DEVELOPMENT MUST BEGIN AT LOCAL LAND MANAGEMENT LEVELS Report to the Chairman, Committee on Energy and Commerce, House of Representatives

4 Dec 1981 24 p refs

(EMD-82-10, B-205344) Avail SOD

A study of the use of Federal lands, particularily military lands, concluded that success in streamling and accelerating mineral development on Federal lands depends on the Bureau of Land Management state offices ultimately responsible for the implementation of Department of Interior minerals policies. It was found the eastern States Office of the Bureau of Land Management did not effectively deal with potential Federal mineral trespass in the East, and was unable to issue mineral leases and permits on a timely basis. Moreover, it was unable to effectively deal with new areas of mineral interest because of Department actions. Recommendations to improve the mineral trespass program help relieve lease and permit backlogs, maintain dedicated staff, and improve headquarters communications with State offices were made R.IF

INPE-2367-RA/161-PT-2) Avail NTIS HC A03/MF A01 CSCL 08N

Geomagnetic field variations were studied by considering the parameter delta H which indicated H(observed) minus H(model), where H = (X squared + Y squared) (1/2) where X, Y, and Z

are the components actually observed. Quiet time base values for 5 deg longitude belts were estimated After subtracting these from the observed values, the residual delta H (dawn) and delta H (dusk) were studied for the two major storms. It was noticed that the dusk values attained larger (negative) values for a longer time, than the dawn value Some changes in delta Y and delta Z were also noticed, indicating possibilities of either meridional currents and/or noncoincidence of the central plane of the ring current with the equatorial plane of the Earth Other details are described. PREFLARE INCREASES IN SOLAR COSMIC RAYS RELEVANT TO THE MODE OF ENERGY ACCUMULATION IN THE ACTIVE **REGIONS ASSOCIATED WITH LARGE FLARES**

G. M. BLOKH, O. P. GRIGORIAN, and B. M KUZEVSKII (Moskovskii Gosudarstvennyi Universitet, Moscow, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 77-80. refs

Evidence of preflare increases in the electron and proton solar cosmic ray components is analyzed to develop a model of the processes involved. Data from the Prognoz-6 and Helios-1 and -2 satellites are cited as proof of a temporal form of particle arrival similar to a flare-produced event. The electron data indicates a set of individual events of acceleration up to 5 MeV and proton data shows the same process up to tens of MeV, implying a

quasicontinuous generation of particles The low-energy particle increase has been observed to occur several days in advance of a flare, with the particle acceleration happening in subregions of an imminent flare event. It is suggested that Coulomb interactions in the two-component plasma are responsible for the accelerations, which do not culminate in a flare until the ionization energy loss on the electrons and protons becomes insignificant compared to the acceleration rate M.S.K.

A82-22596

COMPARISON OF SOLAR PROTON ACTIVITY IN 1967 AND 1969 WITH THAT IN 1978 AND 1979 AS MEASURED ONBOARD VENERA 4, 6, 11, 12 SPACE PROBES

S. I ERMAKOV, N. N KONTOR, G. P. LIUBIMOV, N. V. PERESLEGINA, and T. G. KHOTILOVSKAIA (Moskovskii Gosudarstvennyi Universitet, Moscow, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 81-84.

A comparison of the proton activity in 1967 and 1969 with that in 1978-1979 shows that proton activity in 1967 was much below the level of 1978-1979 owing to the high solar activity during the rise phase of the 21st cycle. It is also found that the activity in 1969 was much above the level of 1978-1979, although the smoothed sunspot number was approximately 110 This is seen as indicating that proton activity is weakly correlated with the smoothed sunspot number and is determined largely by the phase of the solar cycle. The greatest proton activity was observed in phases of maximum solar activity and solar activity decay CR

MAGNETIC ANOMALIES AS A REFERENCE FOR GROUND-SPEED AND MAP-MATCHING NAVIGATION

C. TYREN Journal of Navigation, vol. 35, May 1982, p. 242-254 The use of the earth's magnetic field for ground referenced motion and position measurements is discussed A magnetic terrain-navigation concept is set forth, and its sensor configuration, data processing and data storage unit, and navigation data interface unit are discussed. The navigational accuracy of the system is assessed, one particular advantage of terrain navigation systems is that ground-speed accuracy is independent of vehicle speed until speeds are reached at which the sensors and/or computer operations are too slow to track the vehicle path. The system is therefore excellent at low speeds and can advantageously be used for hovering operations. The results of field tests indicate that the feasibility of both ground-speed and map-matching methods is indeed promising. C D.

INITIAL VECTOR MAGNETIC ANOMALY MAP FROM MAGSAT R. A. LANGEL, C. C SCHNETZLER (NASA, Goddard Space Flight Center, Greenbelt, MD), J. D. PHILLIPS (U.S. Geological Survey, Reston, VA), and R. J. HORNER (Computer Sciences Corp., Silver Spring, MD) Geophysical Research Letters, vol 9, Apr. 1982, p. 273-276. refs

Global magnetic component anomaly field maps have been derived from the Magsat vector magnetometer data obtained from November 1979 through May 1980 The amplitude of variations of the components over the maps are between 10 and 15 nT, well above the noise in the data. Averaged data, in 2-by-2 deg blocks, exhibit standard errors of the mean of about 1 nT over most of the X and Z maps, and about 2 nT over most of the Y maps. Errors rise to about twice these amounts near the auroral belts. Most of the anomalies in the component data are consistent with a crustal magnetization model which incorporates dipoles aligned only in the direction of the main field. However, there appear to be some regions which require dipoles aligned in some other direction i.e., remanent magnetization (Author)

A SATELLITE MAGNETIC MODEL OF NORTHEASTERN SOUTH AMERICAN AULACOGENS

M. B. LONGACRE, W. J. HINZE, and R. R. B. VON FRESE (Purdue University, West Lafayette, IN) Geophysical Research Letters, vol. 9, Apr. 1982, p 318-321 refs (Contract NAS5-25030)

Magnetic modeling of the Amazon River and Takatu Aulacogens in northeastern South America illustrate the utility of satellite magnetic data in characterizing the properties and structure of the lithosphere. Specifically, reduction of preliminary Magsat scalar magnetic anomaly data to an equivalent condition of vertical polarization shows a general correlation between magnetic anomaly minima and the Amazon River and Takatu Aulacogens. Surface gravity data demonstrate a correlative positive anomaly Spherical earth modeling of the magnetic data indicates a less magnetic crust associated with the aulacogens which is compatible with previous studies over the Mississippi River Aulacogen and Rio Grande Rift in North America. ALBEDO AND ANGULAR CHARACTERISTICS OF THE REFLECTANCE OF THE UNDERLYING SURFACE AND CLOUDS [AL'BEDO I UGLOVYE KHARAKTERISTIKI OTRAZHENIIA PODSTILAIUSHCHEI POVERKHNOSTI I OBLAKOV]

K. IA. KONDRATEV, V. I. BINENKO, L. N. DIACHENKO, V. I. KORZOV, and V V MUKHENBERG Leningrad, Gidrometeoizdat, 1981 232 p In Russian refs

Information on the reflectance in the short-wave region of the spectrum of clouds and of the system comprising the earth's surface and atmosphere is discussed. Data are presented on the total albedo of the underlying surface and on the geographical distribution of albedo. Attention is given to the principles determining the spectral distribution of the albedo. Also considered are the laws governing the angular distribution of the reflectance of various types of natural formations CR.

A82-31994* Kansas Univ Center for Research, Inc., Lawrence. THE RECOGNITION OF EXTENDED TARGETS - SAR IMAGES FOR LEVEL AND HILLY TERRAIN

J A. STILES, V. S. FROST, J. C HOLTZMAN, and K S SHANMUGAM (University of Kansas Center for Research, Inc., Lawrence, KS) IEEE Transactions on Geoscience and Remote Sensing, vol. GE-20, Apr 1982, p. 205-211. Research supported by the California Institute of Technology refs (Contract NAS7-100)

Radar image simulation techniques are used to determine the character of SAR images of area-extensive targets, for the cases of flat underlying terrain and of moderate relief, with a view to the severity of elevation change effects on the detection and recognition of boundaries and shapes. The experiment, which demonstrated these effects on shapes and boundaries, was performed in order to establish Seasat-A SAR performance. Attention is given to the geometry/propagation effects in range perspective imaging that must be known for information extraction.

A82-32078* Joint Inst. for Lab. Astrophysics, Boulder, Colo ESTABLISHMENT OF TERRESTRIAL REFERENCE FRAMES BY NEW OBSERVATIONAL TECHNIQUES

P L. BENDER (Joint Institute for Laboratory Astrophysics, National Bureau of Standards, Quantum Physics Div, Boulder, CO) In Reference coordinate systems for earth dynamics, Proceedings of the Fifty-sixth Colloquium, Warsaw, Poland, September 8-12, 1980. Dordrecht, D. Reidel Publishing Co., 1981, p 23-36 NBS-supported research refs

(Contract NASA ORDER S-65000-B)

It is anticipated that terrestrial reference systems for geodynamics studies which include adopted plate motion models will be introduced for the analysis of both LAGEOS satellite and very long baseline interferometry ranging data. One of the possible approaches involves adjustment of ground station coordinates in conjunction with solutions for Universal Time 1 (UT1) and polar motions as functions of time. Another method uses principal value decomposition to reduce the number of degrees of freedom being solved for by three In a third alternative, the values of UT1 and polar motion derived from the available data by means of the initial set of coordinates are kept fixed, and an appropriate block of data is reanalyzed using the previously determined values of UT1 and polar motion so that a new set of station coordinates can be derived OC.

THE DEFINITION OF THE TERRESTRIAL COORDINATE FRAME BY LONG BASELINE INTERFEROMETRY

W. H. CANNON (York University, Toronto, Canada) and M. G ROCHESTER (Newfoundland, Memorial University, St. John's, Canada) In. Reference coordinate systems for earth dynamics, Proceedings of the Fifty-sixth Colloquium, Warsaw, Poland, September 8-12, 1980. Dordrecht, D. Reidel Publishing Co., 1981, p. 111-118. refs

This paper examines the question of the definition of the celestial and terrestrial coordinate frames by the technique of long baseline interferometry. It demonstrates how the celestial coordinate frame may be usefully defined in terms of basis I-forms associated with the advancing phase fronts of the radiation fields from compact radio sources using only interferometer observables. The paper then proceeds to show how the terrestrial coordinate frame could be usefully defined, incorporating fully the effects of plate tectonics and secular motion of the observatories, by an application of the theory of continuum mechanics to interferometer observations. ORIGIN AND SCALE OF COORDINATE SYSTEMS IN SATELLITE GEODESY

J. B. ZIELINSKI (Polska Akademia Nauk, Centrum Badan Kosmicznych, Warsaw, Poland) In: Reference coordinate systems for earth dynamics, Proceedings of the Fifty-sixth Colloquium, Warsaw, Poland, September 8-12, 1980. Dordrecht, D. Reidel Publishing Co, 1981, p 239-250. refs

The center of mass of the earth is commonly taken as origin for the coordinate systems used in satellite geodesy. In this paper the notion of the 'geocenter' is discussed from the point of view of mechanics and geophysics. It is shown that processes in and above the crust have practically no impact on the position of the geocenter. It is possible however that motions of the inner core may cause variations of the geocenter of the order of 1 m. Nevertheless the geocenter is the best point for the origin of a coordinate system. Mather's method of monitoring geocenter motion is discussed, and some other possibilities are mentioned. Concerning the scale problem, the role of the constant GM and time measurements in satellite net determinations are briefly discussed. (Author)

GEOID HEIGHT-AGE RELATION FROM SEASAT ALTIMETER PROFILES ACROSS THE MENDOCINO FRACTURE ZONE

D. T. SANDWELL and G. SCHUBERT (California, University, Los Angeles, CA) Journal of Geophysical Research, vol 87, May 10, 1982, p. 3949-3958. refs

(Contract NAG5-152)

Twenty-eight Seasat altimeter profiles crossing the Mendocino Fracture Zone are used together with seafloor ages determined from magnetic lineations to estimate the change in oceanic geoid height with age, between ages of 15 and 135 m.y. An unbiased estimate of the overall geoid offset along each profile is determined from a least-squares fit of the along-track derivative of the geoid to the geoid slope predicted from a simple two-layer gravitational edge effect model. Uncertainties based upon the statistical properties of each profile are also determined A geoid slope-age relation is constructed by normalizing the geoid offsets and uncertainties by the age offsets. The results are in agreement with geoid slope-age relations determined from symmetrically spreading ridges (Sandwell and Schubert, 1980). However, the fracture zone estimates have smaller uncertainties and show less scatter. A comparison of these results with the good slope-age prediction of the boundary layer cooling model shows that the thermal structure begins to deviate from this model at an early age (20-40 m.y.). A plate cooling model with a thickness of 125 km is most compatible with the geoid slope-age estimates, although significant deviations occur, these may indicate that the lithospheric thermal structure is not entirely age dependent. COMPARING LINEAMENTS INTERPRETED FROM LANDSAT IMAGERY AND TOPOGRAPHIC MAPS WITH REPORTED FAULTS IN SOUTHWEST MONTANA

R. C. HOWE and D M. THOMPSON (Indiana State University, Terre Haute, IN) In: American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p 237-246 refs

Poor resolution has usually prevented detection of features smaller than 60 by 80 meters on Landsat imagery. However, features previously not known to be related have been shown to be continuous or semicontinuous over large distances as a result of the synoptic view provided by satellites. In particular, numerous authors have noted the usefulness of Landsat imagery for lineament interpretations. The present investigation has the objective to compare the results of the lineament interpretation from Landsat imagery and topographic maps with reported faults in a portion of southwest Montana. The 1:1,000,000 color composite Landsat image was found to be clearly superior to 1:250,000 topographic maps for detecting lineaments Almost twice as many lineaments were visible on the image as could be interpreted from the maps. However, the number of reported faults matching lineaments interpreted from each of these two data bases was similar. G.R.

The results of modeling satellite-elevation magnetic and gravity data using the constraints imposed by near surface data and seismic evidence shows that the magnetic minimum can be accounted for by either an intracrustal lithologic variation or by an upwarp of the Curie point isotherm. The long wavelength anomalies of the NOO's-vector magnetic survey of the conterminous U.S. were contoured and processed by various frequency filters to enhance particular characteristics. A preliminary inversion of the data was completed and the anomaly field calculated at 450 km from the equivalent magnet sources to compare with the POGO satellite data. Considerable progress was made in studing the satellite magnetic data of South America and adjacent marine areas. Preliminary versions of the 1 deg free-air gravity anomaly map (20 m gal contour interval) and the high cut (lambda approximately 8 deg) filtered anomaly maps are included A.R.H.

The time scale and time lapse over which crustal movements are traditionally monitored by geodesy and seismology was studied. Efforts are made to bridge this gap through increasing the frequency of geodetic measurements in the regions of particular interests, establishment of a global network of long and ultralong period seismometers, and development of geophysical and geodetic intrumentation that should be capable of measuring rates of crustal deformation over arbitrary time scales. The following measurements were undertaken: (1) on a global scale; (2) deformation near active plate boundaries; (3) deformation within plate interiors and other neotectonic motion; and (4) instrumentation for measuring tectonic deformation. Programs are being adapted to the UNIVAC 1000 computer and others are being developed for immediate utilization in processing MAGSAT data. The magnetization intensity, susceptability, Koeningsberger ratio, NMR stbility against alternated fields and temperature, and the Curie temperature were determined for some rock formations with mineralogical compositions stable to the intermediate for lower continental crust and to upper manele conditions. Attempts to residuate crustal anomalies from one selected profile passing through western mediterranean using procedures commonly used at NASA yielded dubious results because of uncertainties in the adoption of coefficients in the expression accounting for the effect of equatorial ring currents and the empirical approach used for other corrections. Instead, filtering techniques are to be applied to each profile once invesigator B tapes relative to the whole planet are received.

Preliminary results of MAGSAT data analysis are described. Regional anomaly maps (deviations from the MGST model field) for X,Y,Z, and F in the area of 115 to 155 deg E and 20 to 60 deg N were obtained. A similar map for the geomagnetic total force anomaly in the vicinity of Japan showed that the observed anomaly can be explained by the difference in crustal magnetization between the Japan Sea and the Japan Island, which reflects a difference of 25 km in the thickness of the magnetized layer. The MAGSAT record of a sudden comencement of a magnetic storm above the South Atlantic Ocean showed a reverse impulse particularly in the D-component. Results relating to toroidal currents in the ionosphere, transverse and parallel perturbations over the polar regions, the relationship between field aligned currents and precipitating electrons, and the calculation of the subsatellite electric field are also discussed MG

INVESTIGATION OF ANTARCTIC CRUST AND UPPER MANTLE USING MAGSAT AND OTHER GEOPHYSICAL DATA Quarterly Status Technical Progress Report

C. R. BENTLEY, Principal Investigator 16 Apr. 1982 1 p ERTS

(Contract NAS5-25977)

(E82-10309; NASA-CR-168884; NAS 1.26:168884; QSTPR-9) Avail: NTIS HC A02/MF A01 CSCL 08G

Plans to create an improved version of the MAGSAT magnetic anomaly map by more carefully scrutinizing the accepted data for field-aligned current effects are discussed. Data are continued to a 300 km surface for the compilation of a final map. Based on this set of data, vector anomaly maps over Antarctica are planned. A high-pass anomaly map with a cut-off wavelength of approximately 1500 km is also envisioned It is suspected that longer-wavelength features have their origin outside the crust.

INVESTIGATION OF GEOMAGNETIC FIELD FORECASTING AND FLUID DYNAMICS OF THE CORE Quarterly Progress Report, 1 Jan. - 31 Mar. 1982

E. R. BENTON, Principal Investigator 1 Apr. 1982 7 p refs ERTS

(Contract NAS5-25957)

(E82-10310, NASA-CR-168885; NAS 1.26:168885, QPR-9) Avail NTIS HC A02/MF A01 CSCL 08G

It was established that the total absolute magnetic flux crossing the core- mantle boundary has been a constant of the core motion for the last 50 years. This provides a scalar constraint that could be added to the geometric modelling procedure. The GSFC 8 8/80 model is being evaluated. The absolute magnetic flux linking the CMB to that model was plotted as a function of time during the span covered by the data, and increasing truncation level. The inclusion of the standard error of each Gauss coefficient derived from the statistics of fit in the GSFC 9/80 model is useful. The magnitude and sense (upwelling or downe welling) of vertical fluid motion adjacent to the core-mantle boundary was calculated using the model. Standard errors were found to be sufficiently small at all but one or two of the 40 or more critical points of B sub r They do not nearly overlap the value gamma u/gamma r = 0. It is concluded that the core is upwelling and downwelling at an observationally detectable level A.R.H.

MAGNETIC AND GRAVITY ANOMALIES IN THE AMERICAS Quarterly Progress Report, Oct. - Dec. 1981

L W. BRAILE, W. J. HINZE, and R. R. B. VONFRESE, Principal Investigators 30 Dec 1981 7 p Sponsored by NASA ERTS (E82-10312; NASA-CR-168888; NAS 1 26 168888) Avail NTIS HC A02/MF A01 CSCL 05B

The cleaning and magnetic tape storage of spherical Earth processing programs are reported. These programs include. NVERTSM which inverts total or vector magnetic anomaly data on a distribution of point dipoles in spherical coordinates; SMFLD which utilizes output from NVERTSM to compute total or vector magnetic anomaly fields for a distribution of point dipoles in spherical coordinates; NVERTG; and GFLD. Abstracts are presented for papers dealing with the mapping and modeling of magnetic and gravity anomalies, and with the verification of crustal components in satellite data.

(E82-10314; NASA-CR-168889, NAS 1 26 168889) Avail: NTIS HC A02/MF A01 CSCL 08G

The routine correction of MAGSAT vector magnetometer data for external field effects such as the ring current and the daily variation by filtering long wavelength harmonics from the data is described. Separation of fields due to low altitude sources from those caused by high altitude sources is affected by means of dual harmonic expansions in the solution of Dirichlet's problem. This regression/harmonic filter procedure is applied on an orbit by orbit basis, and initial tests on MAGSAT data from orbit 1176 show reduction in external field residuals by 24.33 nT RMS in the horizontal component, and 10.95 nT RMS in the radial component J.D. AN INVESTIGATION OF MAGSAT AND COMPLEMENTARY DATA EMPHASIZING PRECAMBRIAN SHIELDS AND ADJACENT AREAS OF WEST AFRICA AND SOUTH AMERICA Quarterly Report, period ending 30 Sep. 1981

D A HASTINGS, Principal Investigator 30 Sep. 1981 34 p Sponsored by NASA ERTS

(Contract DI-14-08-0001-16439)

(E82-10316; NASA-CR-168897; NAS 1.26:168897) Avail: NTIS HC A03/MF A01 CSCL 08B

Accomplishments with regard to the mapping and analysis of MAGSAT data for the investigation of correlations between the magnetic field characteristics of South American and African shields are reported Significant results in the interpretation of the global total-field anomalies and the anomaly patterns of Africa and South America are discussed. The central position of the Brazilian shield tends to form a negative total-field anomaly, consistent with findings for shields in equatorial Africa. Sedimentary sequences in the Amazon basin and in the Rio de Janeiro-Sao Paolo areas exhibit positive anomalies, also consistent with equatorial Africa. Results for the Caribbean Sea and Guyana regions are also described.

Several possible causes for the east-west striping of the MAGSAT anomaly maps are listed and discussed including. (1) the inadequacy of the field model used for core-crustal separation of geomagnetic anomalies; (2) external field noise remaining in the available maps, (3) east-west trends of crustal uplift and depression; (4) east-west trends to convection patterns in the mantle; (5) bands of crustal materials of similar metamorphic grade, (6) variations in the depth of the Curie isotherm; and (7) the data processing techniques used to overcome the absence of tie lines and orbital path of MAGSAT M.

The problems associated with the use of an interactive magnetic modeling program are reported and a publication summarizing the MAGSAT anomaly results for Africa and the possible tectonic associations of these anomalies is provided. An overview of the MAGSAT scalar anomaly map for Africa suggested a correlation of MAGSAT anomalies with major crustal blocks of uplift or depression and different degrees of regional metamorphism The strongest MAGSAT anomalies in Africa are closely correlated spatially with major tectonic features. Results indicate that the Bangui anomaly may be caused by a central old Precambrian shield, flanked to the north and south by two relatively young sedimentary basins.

MAGSAT ANOMALY MAP AND CONTINENTAL DRIFT Progress Report

J. L LEMOUEL, Principal Investigator, A. GALDEANO, and J. DUCRUIX 1 Dec 1981 5 p refs Sponsored by NASA ERTS

(E82-10326; NASA-CR-168905; NAS 1.26:168905) Avail: NTIS HC A02/MF A01 CSCL 08G

Anomaly maps of high quality are needed to display unambiguously the so called long wave length anomalies. The anomalies were analyzed in terms of continental drift and the nature of their sources is discussed. The map presented confirms the thinness of the oceanic magnetized layer. Continental magnetic anomalies are characterized by elongated structures generally of east-west trend. Paleomagnetic reconstruction shows that the anomalies found in India, Australia, and Antarctic exhibit a fair consistency with the African anomalies. It is also shown that anomalies are locked under the continents and have a fixed geometry. T.M.

(E82-10330; NASA-CR-168909; NAS 1.26:168909) Avail: NTIS HC A02/MF A01 CSCL 08G

Efforts concerning spherical harmonic modeling of the Earth's magnetic field and the use of such models in removing core produced magnetic fields from magnetic fields of crustal origin are discussed Results indicate that the terms of a spherical harmonic expansion do not uniquely determine a given wavelength of signal as the terms in a Fourier series do. Addition of terms of higher degree and order to a spherical harmonic expansion tend to fine tune the amplitude of the terms of lower degree and order. As a result, removal of such a model from a regional data set will not remove long wavelengths completely M.G

A COMPARISON OF POLE POSITIONS DERIVED FROM GPS SATELLITE AND NAVY NAVIGATION SATELLITE OBSERVATIONS

W. H. WOODEN, II 6 Jan. 1982 18 p refs Presented at the 3rd Intern. Geodetic Symp. on Satellite Doppler Positioning

(AD-A110765) Avail: NTIS HC A02/MF A01 CSCL 17G

The observation of the motion of the Earth's spin axis with respect to the crust has been done continuously since the latter part of 1899 by the International Service. With the advent of new technologies, new determinations of polar motion have been possible Doppler tracking of the Navy Navigation Satellites has provided estimates of the polar motion on a permanent basis since 1969. Currently, these estimates are done at the Defense Mapping Agency and are distributed to several agencies including the Bureau International de l'Heure (BIH), which has the responsibility of centralizing polar motion data. The NAVSTAR Global Positioning System (GPS) is a new navigation satellite system which will eventually replace the existing Navy Navigation Satellite System. As a byproduct of the orbit estimation process for the GPS satellites, values for the position of the pole are

determined. In this paper the two different methods for computing the pole's position from satellite observations are described. The most recent results from each method are compared to each other and to the standard BIH values. Author (GRA)

THE EARTH'S GRAVITY FIELD TO DEGREE AND ORDER 180 USING SEASAT ALTIMETER DATA, TERRESTRIAL GRAVITY DATA AND OTHER DATA

R. H. RAPP Hanscom AFB, Mass AFGL Dec. 1981 58 p refs

(Contract F19628-79-C-0027, AF PROJ. 2309)

(AD-A113098, DGS-322; SCIENTIFIC-12; AFGL-TR-82-0019) Avail: NTIS HCA04/MF A01 CSCL 08N

The spherical harmonic expansion of the Earth's gravitational field has been obtained to degree 180 by combining several sources of data The first data set was an a priori set of potential coefficients to degree 36 based on number of recent solutions including a substantial of resonance terms. A second data set was a 1 x 1 deg anomaly field derived from the SEASAT data set, while the third data set was an updated 1 x 1 deg terrestrial field. The last two fields were combined into one set containing 56761 1 x 1 deg values. The remaining values were computed from the a priori potential coefficients. A rigorous combination solution was not carried out. Instead all anomalies were weighted in such a way that the normal equations were diagonal. The results of the adjustment were 64800 1 x 1 deg anomalies that were expanded into spherical harmonics using the optimum quadrature procedure developed by Colombo Accuracy estimates for each coefficient were obtained considering noise propagation and sampling error caused by the finite block size in which the anomalies are given The percentage error of the solution reaches 100% near degree 120. The coefficients and their accuracy to degree 50 are listed in an appendix. GRA

EXTRAGALACTIC COSMIC RAYS, THEIR SOURCES AND SPECTRUM

R. SILBERBERG and M. M SHAPIRO (U.S. Navy, Naval Research Laboratory, Washington, DC) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 356-359 refs

Studies of air showers, particularly by Watson et al (1980), have shown that cosmic rays at energies above 10 to the 19th eV are likely to be extragalactic in origin. The energy density above 10 to the 19th eV is 3 x 10 to the -8th eV/cu cm, and the exponent of the integral energy spectrum is -1.4 plus or minus 0.1. For estimating the energy density of relativistic protons (E greater than GeV) in metagalactic space an energy input rate W sub p into protons similar to that for relativistic electrons (W sub e) in active galactic nuclei is assumed. For cosmic rays in the supercluster, W sub p is found to be 10 to the -4th (plus or minus 1) eV/cu cm. This estimate for W sub p is supported by the following internal consistency argument: this spectrum at 10 to the 9th eV, when extended with an exponent -1.4, smoothly joins the extragalactic spectrum at 10 to the 19th eV, having a similar spectral slope (The exponent -1 4 also is that of galactic cosmic rays when corrected for rigidity-dependent leakage from the Galaxy.) (Author)

THE APPROXIMATE 1 GEV SOLAR COSMIC RAYS IN THE FORBUSH-EFFECT OF FEBRUARY 15, 1978

G P. LIUBIMOV, V I TULUPOV, and E A. CHUCHKOV (Moskovskii Gosudarstvennyi Universitet, Moscow, USSR) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 121-123 refs

Differences in the behavior of the galactic cosmic-ray intensity are studied using the data from the Alert and Deep River neutron monitors from February 14 to 17, 1978. The behavior of the intensity at Alert and Deep River is normalized to the initial stage of February 14, before the Forbush effect, and the additional differential flux reaches 15 percent. The observed anomalous differences are explained by an additional particle flux of about 1 GeV of solar origin in the Forbush effect. D L.G.

BMFT-01-01-017-ZA/WF/WRK-1754 ; NGR-21-002-224,

NGR-21-002-316)

The ionization states and spectra of 0.3 to 2.4 MeV/nuc He, C, O and Fe are measured in a survey of ten solar flare particle events. He(plus) is found to be present in all events, which indicates the common presence of energetic He(plus) in the source material from which solar particles are accelerated. The distribution functions of He(plus), He(plus plus) and heavier elements are represented by simple exponentials of the particle speed times its rigidity to a power n, where n is between 0 and 1, and equal e-folding values. Results are consistent with a model where ions are accelerated in the corona by multi-dimensional shocks out of a population taken from both hot and cold coronal regions. D.L.G.

REGIONAL GEOLOGICAL, TECTONIC AND GEOPHYSICAL FEATURES OF NORDLAND, NORWAY

R. H. GABRIELSEN, I. B. RAMBERG (Oslo, Universitetet, Oslo, Norway), M. B E. MORK (Universitets Minelarogisk Geologiske Museum, Oslo, Norway), and B TVEITEN (BP Petroleum Development of Norway, A/S, Stavanger, Norway) Earth Evolution Sciences, vol. 1, Mar. 1981, p. 14-26. Research supported by the Norges Almenvitenskapelige Forskningsrad, Committee for Geophysics and Geology and Norges Teknisk-Naturvitenskapelige Forskningsrad refs

(Contract NTNF PROJECT 18108075)

Foliation and lineament patterns from Landsat imagery, gravity and magnetic data mapping of Nordland, Norway shows a high degree of correlation with known tectonostratigraphic units and suggests other, previously unidentified tectonic units. Attention is given to regionally important lineament systems, one striking approximately ENE-WSW, and a younger one N-S. It is indicated by the large-scale residual gravity lows along the Norway-Sweden border, which are associated with basement domes, and by magnetic data and lineament patterns, that the eastern basement windows represent large-scale culminations. By contrast, the western domes represent smaller, perhaps granitic cores of recumbent fold nappes. A positive correlation is found between the seismotectonic coastal zones of Nordland and the area's Bouguer gravity anomally maximum gradient O.C.

A82-30305

SATELLITE IMAGE INTERPRETATION OF THE EASTERN CALEDONIAN PART OF THE BLUE ROAD GEOTRAVERSE AND ITS GEOLOGICAL IMPLICATIONS /NORDLAND, VASTERBOTTEN, SCANDINAVIA/

R. GREILING (Mainz, Universitaet, Mainz, West Germany) Earth Evolution Sciences, vol. 1, Mar. 1981, p. 27-30. refs

An 80% coincidence of known geological features with the lineaments interpreted in the satellite image presented by Ehrenborg (1977) is found through the quantitative study of Landsat interpretations for the case of a Precambrian area in southeastern Sweden Because of its probable connection with the quaternary glacial erosion, the distribution of joints and faults may be interpreted as (1) E-W-striking lineaments locally correlated with faults affecting Caledonian low-angle thrusts and folliations, (2) NW-SE lineaments locally correlated with leucocratic dikes, and (3) NNW-SSW lineaments generally parallel to the present coast which, by contrast to the region farther west, is of minor importance.

MAGSAT SCALAR ANOMALY DISTRIBUTION - THE GLOBAL PERSPECTIVE

H. FREY (NASA, Goddard Space Flight Center, Geophysics Branch, Greenbelt, MD) Geophysical Research Letters, vol. 9, Apr. 1982, p. 277-280. refs

It is established that geographic coincidences exist between high-altitude Magsat scalar anomalies and major geologic and tectonic structures, with oceanic abyssal plains overlain by negative anomalies agreeing well in spatial extent and position and submarine platforms lying beneath positive scalar anomalies. In addition, geographic coincidence is found in the continents between many high-latitude positive anomalies and shields and cratons in North America, Eurasia and Australia. While these correlations are qualitative, they serve to identify regions for detailed study. The global distribution of anomalies provides a basis for comparative study which will be enhanced when reduced-to-pole versions of the Magsat data become available O.C.

SPECTROSCOPIC REMOTE SENSING FOR GEOLOGICAL APPLICATIONS

A F. H. GOETZ (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA) In Imaging spectroscopy; Proceedings of the Seminar, Los Angeles, CA, February 10, 11, 1981. Bellingham, WA, SPIE - The International Society for Optical Engineering, 1981, p. 17-21. refs

(Contract NAS7-100)

Remote sensing is being used with increasing frequency in the development of geologic maps and in the exploration process Spectral data from airborne and spaceborne multispectral scanners provide information on rock type and vegetation stress, important in geologic applications. Emphasis is now being placed on direct identification of materials rather than discrimination among geologic units. To do this, higher spectral resolution systems with wider spectral coverage than currently available are required. Imaging spectroscopy in the 0.4 - 14 microns region appears to be the answer (Author)

POSSIBLE FAULT DETECTION IN COTTONBALL BASIN, CALIFORNIA AN APPLICATION OF RADAR REMOTE SENSING

G. L BERLIN, G. G SCHABER, and K. C. HORSTMAN (U.S. Geological Survey, Flagstaff, AZ) Remote Sensing of Environment, vol 10, Aug. 1980, p. 33-42 refs

An analysis of a 3-cm wavelength radar image of Cottonball Basin in Death Valley National Monument has revealed the existence of two suspect fault traces in evaporite deposits that are less than 2000-yr old The traces are well defined on the image because the radar system was able to differentiate surface roughness variations at the centimeter scale. The features are not recognizable on data sets recorded in the visible and near-infrared spectral bands. Results indicate the potential of radar images as a tool to help locate recent breaks along a fault when the disturbed zone is represented by a somewhat rougher surface than is found in immediately adjacent areas. AEROGEOPHYSICAL METHODS OF FINDING URANIUM DEPOSITS [AEROGEOFIZICHESKIE METODY PROGNOZIROVANIIA MESTOROZHDENII URANA]

A I KRASNOV, E. B. VYSOKOOSTROVSKAIA, V. A. SMIRNOV, IU. B NOVIKOV, E. I ZUBOV, G B. MUKAREVA, L. V. DIORDIENKO, and V. G. ZAITSEV Moscow, Atomizdat, 1980. 132 p. In Russian. refs

Geophysical prospecting for uranium with the aid of a large-scale, comprehensive gamma-spectrometric, aeromagnetic, and aeroelectric survey is considered. The development in the USSR and in other countries of aerogeophysical prospecting for uranium is surveyed. Features of geophysical fields that are characteristic of regions containing endogenous and exogenous deposits of uranium are analyzed. Direct and indirect radiogeochemical, magnetogeophysical, and electrogeophysical indicators of uranium-bearing structures are described. The methods described here rely on a comprehensive interpretation of aerogeophysical, geological, and other types of data. C.R **A82-34721*** National Aeronautics and Space Administration. LANDSAT IN THE SEARCH FOR APPALACHIAN HYDROCARBONS

H. W. BLODGET (NASA, Goddard Space Flight Center, Eastern Regional Remote Sensing Applications Center, Greenbelt, MD) In: American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers Falls Church, VA, American Society of Photogrammetry, 1981, p. 259-262. refs

A study has been conducted to determine the applicability of enhanced Landsat imagery for oil and gas exploration in Appalachia Attention was given to the feasibility to employ lineaments identified on Landsat imagery as a tool in petroleum exploration. Lineaments, as defined in this connection, are linear or sublinear traces seen on Landsat imagery. They frequently reflect subsurface geological structures. The investigation was conducted in two stages. The first was designed to identify the specific Landsat imagery enhancement best suited for displaying lineaments. The second stage consisted of plotting lineaments and conducting an analysis of the lineament trends with regard to both local geological structure and regional tectonics A close relationship was observed between lineaments identified on Landsat imagery and known oil and gas reservoirs. This result suggests that lineaments can be related to the structural control of oil and gas reservoirs throughout Appalachia GR

A82-36298* Lunar and Planetary Inst., Houston, Tex. INFLUENCE OF CO2 ON MELTING OF MODEL GRANULITE FACIES ASSEMBLAGES - A MODEL FOR THE GENESIS OF CHARNOCKITES

R. F. WENDLANDT (Lunar and Planetary Institute, Houston, TX) American Mineralogist, vol. 66, 1981, 1164-1174. refs (Contract NASW-3389)

A model is described for the melting of a simple granulite assemblage, in the presence of CO2-rich fluid phases, which can occur between 750 and 1000 C at crustal pressures and is therefore within the range estimated for such regional metamorphism as that of the Adirondacks For melting which occurs at about 750 C in the presence of both H2O and CO2, pressures corresponding to the deep crust are required to generate a melt enriched in pyroxene and feldspar components, while melting the precense of pure CO2 at about 1000 C generates analogous melt compositions at lower pressures. These experimental reactions are in keeping with observations constraining charnockite occurrences (1) pressure and temperature constraints; (2) mineralogical constraints, and (3) constraints on the compositions of volatiles associated with peak conditions of charnockite formation O C.

SIGNIFICANCE OF TECTONICS IN LINEAR FEATURE DETECTION AND INTERPRETATION ON SATELLITE IMAGES F. CSILLAG (Eotvos Lorand Tudomanyegyetem, Budapest, Hungary) Remote Sensing of Environment, vol. 12, July 1982, p.

235-245. refs There are two main concepts of linear feature evaluation based on satellite images. One puts emphasis on finding equivalence between the image and the field data, in the other, the basic aim is to correlate them after their more or less separate interpretation A comparative study of the two methods has been carried out on a test field in Southwest Hungary using several kinds of geological and geophysical data as reference. Combining the statistical and deterministic approach a block-faulting mechanism can be recognized and described with ENE-WSW main axis. Correlation of satellite and reference data proved the tectonic difference of the northern and southern parts of the test field. This led to the conclusion that one can derive textural information on tectonics from a Landsat image concerning especially short lines. This implies that not only the present surface expression of faults and tectonics is detectable but the determination of the latest tectonically active **N82-22624***# Bureau de Recherches Geologiques et Minieres, Minieres, Paris (France).

SPATIAL THERMAL RADIOMETRY CONTRIBUTION TO THE MASSIF ARMORICAIN AND THE MASSIF CENTRAL FRANCE LITHO-STRUCTURAL STUDY Final Report

Thermal zones delimited on HCMM images, by visual interpretation only, were correlated with geological units and carbonated rocks, granitic, and volcanic rocks were individualized rock signature is evolutive parameter and some distinctions were made by addition of day, night and seasonal thermal image interpretation This analysis also demonstrated that forest cover does not mask the underlying rocks thermal signature. Thermal linears are associated with known tectonics but the observed thermal variations from day to night and from one to another represent a promising concept to be studied in function of neotectonics and hydrogeology The thermal anomalies discovered represent a potential interest which is to be evaluated. Significant results were obtained in the Mont Dore area and additional geological targets were defined in the Paris Basin and the Montmarault granite. Author

OVERSEAS GEOLOGY AND MINERAL RESOURCES NUMBER 56: A GEOLOGICAL INTERPRETATION OF LANDSAT IMAGERY AND AIR PHOTOGRAPHY OF BOTSWANA

D. I. J MALLICK, F HABGOOD, and A. C SKINNER 1981 41 p refs Original contains color maps Original contains color illustrations

(OGMR-56, ISBN-0-11-884138-6) Avail: NTIS HC A03/MF A01; HMSO 5

A 1 1 million geological map compiled from LANDSAT and air photography of Botswana and border areas is presented. The distribution of 22 geological units of Karoo and Precambrian age is shown together with the post-Karoo deposits, differentiated into 7 units, based on geomorphological criteria. The data help distinguish volcanics of the Kanye Group from those of the Ventersdorp Group, and the Transvaal Supergroup from those of the Waterberg Group at localities far from their better exposed outcrop areas in the southeast of the country. Eolian, lacustrine and alluvial components of Kalahari desert superficial deposits are differentiated. The fracture and lineament pattern is only partly evident from the photographs. Author (ESA)

Geologic studies of the South American plate were undertaken. The Guayana shield is reasonably well studied, and although data are sparce, the central Brazilian shield appears similar. Both the Amazon and Parnaiba basins seem to be related to an aulocogen structure. The collection of crustal structure information and the generation of measurement of surface wave dispersion in the shield areascontinues. Long period seismograms are digitized and analyzed Existing crusted and upper mantle studies were indexed. Both MAGSAT scaler and vector magnetic anomaly data were used with regional gravity anomaly data to investigate the regional tectonic features of the South American plate. E.A.K.

APPLICATION OF HCMM DATA TO REGIONAL GEOLOGIC ANALYSIS FOR MINERAL AND ENERGY RESOURCE **EVALUATION Progress Report, Sep. - Nov. 1981**

K. WATSON, Principal Investigator and S. H. MILLER Nov. 1981 4 p Sponsored by NAŠA HCMM

(E82-10153; NASA-CR-168538, NAS 1 26.168538) Avail: NTIS HC A02/MF A01 CSCL 08G

A more accurate algorithm was developed to compute thermal inertia from temperature difference and albedo information. The error of this algorithm is about 1/3 of the measurement error in HCMM as opposed to the current algorithm which can have an error 5 times larger A northeast trending lineament was discovered in southewestern Arizona on enhanced thermal inertia images.

APPLICATION OF HCMM DATA TO REGIONAL GEOLOGIC ANALYSIS FOR MINERAL AND ENERGY RESOURCE **EVALUATION Progress Report, Mar. - May 1981**

K. WATSON, Principal Investigator and S H MILLER May 1981 4 p Sponsored by NASA HCMM

(E82-10243; NASA-CR-168824, NAS 1.26:168824) Avail: NTIS HC A02/MF A01 CSCL 08G

The effects of topographic elevation and slope on thermal images were examined using representative field obstructions of the solar and sky radiation and a simple linearized thermal model. The forms are easily adapted for analysis of HCMM images using the DMA digital terrain data From a representative set of field observations, it was found that flux variations with elevation can cause changes in the mean diurnal temperature gradient from -4 deg to -14 deg per km evaluated at 2000 m Changes in the temperature difference gradient of 1 to 2 C per km are also produced which is equivalent to an effective thermal inertia gradient of 100 W s to the 1/2 power/sg m K/1 per km Exposed bedrock on topographic ridges will appear to have a lower thermal inertia due to the additional effect EA.K.

Personnel matters related to the processing and interpretation of MAGSAT data are reported Efforts are being initiated to determine the crustal geology, structure, and potential economic consequences to be deduced from the satellite magnetic anomalies in conjuction with correlative data A.R H.

N82-24596*# Iowa Univ, Iowa City Dept. of Geology. USE OF MAGSAT ANOMALY DATA FOR CRUSTAL STRUCTURE AND MINERAL RESOURCES IN THE US **MIDCONTINENT** Quarterly Report, period ending 31 Dec. 1981

R. S. CARMICHAEL, Principal Investigator 31 Dec. 1981 31 p refs ERTS

(Contract NAS5-26425)

(E82-10323; NASA-CR-168902; NAS 1.26 168902; QR-4) Avail. NTIS HC A03/MF A01 CSCL 08G

The analysis and preliminary interpretation of investigator-B MAGSAT data are addressed. The data processing included: (1) removal of spurious data points; (2) statistical smoothing along individual data tracks, to reduce the effect of geomagnetic transient disturbances; (3) comparison of data profiles spatially coincident in track location but acquired at different times, (4) reduction of data by weighted averaging to a grid with 1 deg xl deg latitude/longitude spacing, and with elevations interpolated and weighted to a common datum of 400 km; (5) wavelength filtering; and (6) reduction of the anomaly map to the magnetic pole Agreement was found between a magnitude data anomaly map and a reduce-to-the-pole map supporting the general assumption that, on a large scale (long wavelength), it is induced crustal magnetization which is responsible for major anamalies. Anomalous features are identified and explanations are suggested with regard to crustal structure, petrologic characteristics, and Curie temperature isotherms. M.G.

THE INFLUENCE OF AUTOCORRELATION IN SIGNATURE EXTRACTION: AN EXAMPLE FROM A GEOBOTANICAL **INVESTIGATION OF COTTER BASIN, MONTANA**

M. L. LABOVITZ and E. J. MASUOKA, Principal Investigators Dec. 1981 28 p refs Submitted for publication ERTS

(E82-10341; NASA-TM-83871; NAS 1.15.83871) Avail NTIS HC A03/MF A01 CSCL 05B

The presence of positive serial correlation (autocorrelation) in remotely sensed data results in an underestimate of the variance-covariance matrix when calculated using contiguous pixels. This underestimate produces an inflation in F statistics. For a set of Thematic Mapper Simulator data (TMS), used to test the ability to discriminate a known geobotanical anomaly from its background, the inflation in F statistics related to serial correlation is between 7 and 70 times. This means that significance tests of means of the spectral bands initially appear to suggest that the anomalous site is very different in spectral reflectance and emittance from its background sites. However, this difference often disappears and is always dramatically reduced when compared to frequency distributions of test statistics produced by the comparison of simulated training sets possessing equal means, but which are composed of autocorrelated observations Author

Computer printer maps of the magnetic total intensity and the six radiometric parameters were prepared in addition to the radiometric anomaly maps for this area. The magnetic total intensity map displays a rather subdued response pattern of broad low amplitude anomalies over much of the area with an average magnetic intensity of approximately 58,900 gammas. The radiometric response over much of the area is relatively low Equivalent concentrations of uranium, thorium and potassium only rarely exceed 3.2 ppM, 7.5 ppM and 1.4% respectively A number of these zones of increased concentrations show corresponding anomalous responses on the uranium/potassium and/or uranium/thorium pseudo-contour maps Based on this set of computer printer maps alone however, it is, at times, difficult to discern the contribution of coinciding local decreases in the potassium and thorium parameters to these ratio anomalies Based on the criteria stated in the general section on interpretation, a total of seven uranium and seven thorium anomalies were outlined on the interpretation map. DOF

The six Trans-Pecos Texas quadrangles (Van Horn, Pecos, Marfa, Port Stockton, Presidio, and Emory Park) were surveyed. The aeromagnetic gravity and geochemical data, their processing, and their analysis are discussed The geologic history and setting of the Trans-Pecos are discussed along with the uranium potential of the region. Uranium anomalies and occurrences are present in the study area, and information is presented on 33 drill holes into these targets. A folio of maps reduced to a scale of 1:500,000. Geologic maps for each of the six guadrangles are included and the geophysical maps have been prepared to be overlays for the geologic maps. Residual aeromagnetic anomaly, complete Bougner gravity anomaly, flight line index, gravity station index, and anomaly interpretative maps were prepared for each quadrangle. A large suite of digitally processed maps of gravity and aeromagnetic are DOF included.

A82-22306* California Inst. of Tech., Pasadena. LABORATORY STUDIES OF ACTINIDE METAL-SILICATE FRACTIONATION

J. H. JONES and D S. BURNETT (California Institute of Technology, Pasadena, CA) In: Lunar and Planetary Science Conference, 11th, Houston, TX, March 17-21, 1980, Proceedings Volume 2. New York, Pergamon Press, 1980, p 995-1001. refs (Contract NSG-7202)

Actinide and Sm partition coefficients between silicate melt and several metallic phases have been measured. Under reducing conditions Si, Th, U and Pu can be reduced to metals from silicate melts and alloyed with a platinum-gold alloy. U and Pu enter a molten Pt-Si alloy with roughly equal affinity but U strongly partitions into the solid Pt. Th behaves qualitatively the same as Pu but is much less readily reduced than U, and Sm appears to remain unreduced Experiments with Fe metal have shown that the partition coefficients of the actinides between Fe and silicate liquid are extremely low, suggesting a very low actinide concentration in planetary cores Experiments show that platinum metals can efficiently fractionate actinides and fractionate actinides from lanthanides and this process may be relevant to the condensation behavior of these elements from the solar nebula. Pt-metal grains in Allende Ca-Al-rich inclusions appear to be U-poor, although the sub-class of Zr-bearing Pt metals may have high U contents.

FEATURES OF COSMIC RAY VARIATIONS DUE TO VARIATIONS IN THE TOTAL MAGNETIC FIELD OF THE SUN

A. N. CHARAKHCHIAN (Akademila Nauk SSSR, Fizicheskii Institut, Moscow, USSR) and T. N. CHARAKHCHIAN (Moskovskii Gosudarstvennyi Universitet, Moscow, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 202-205. refs

The characteristics of the large-scale variations in cosmic ray intensity associated with variations in the total solar magnetic field are discussed. Particular attention is given to cosmic ray effects connected with solar magnetic field inversion and the presence in the stratosphere of short-range particles during periods of increasing total solar magnetic field, and to zonal cosmic ray modulation in the primary energy range 5-20 GeV which is due largely to magnetic field variations at the periphery of the heliosphere. SEASAT MEASUREMENT SYSTEM **EVALUATION** ACHIEVEMENTS AND LIMITATIONS

D B. LAME and G H BORN (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA) Journal of Geophysical Research, vol 87, Apr. 30, 1982, p. 3175-3178. refs (Contract NAS7-100)

The Seasat project, which demonstrated the feasibility of microwave oceanographic remote sensing, was sponsored by the National Aeronautics and Space Administration and managed by the Jet Propulsion Laboratory. The evaluation of the measurement system (elements of the satellite, the sensors, the data handling, and data processing subsystems) was a key activity of the Seasat project. This paper summarizes the primary achievements and highlights the generic limitations of the evaluation process. Other papers in this issue present details of the geophysical evaluation process carried out under the auspices of the Seasat project

B. D. TAPLEY (Texas, University, Austin, TX), G. H BORN, and M. E. PARKE (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA) Journal of Geophysical Research, vol. 87, Apr. 30, 1982, p. 3179-3188. NASA-supported research. refs

A description is given of the Seasat satellite radar altimeter, which was designed to measure (1) the altitude of the satellite above the ocean surface, (2) surface wave height, and (3) the ocean-surface backscatter coefficient from which wind speed may be inferred. The atmospheric and geophysical effects influencing radar altimeter measurement accuracies and the attendant correction models adopted for the altimeter geophysical data record are summarized, along with Seasat Altimeter/Precision Orbit Determination Experiment Team activities directed towards the validation and improvement of these models and investigations assessing the accuracy of both the altimeter measurements and the computed satellite altitude ephemeris. TIDAL AND GEODETIC OBSERVATIONS FOR THE SEASAT ALTIMETER CALIBRATION EXPERIMENT

J M. DIAMANTE, B C. DOUGLAS, D L. PORTER, and R. P. MASTERSON, JR. (NOAA, National Ocean Survey, Rockville, MD) Journal of Geophysical Research, vol. 87, Apr. 30, 1982, p 3199-3206. refs

As part of the Seasat calibration activities of September and October 1978, a tide gage was installed by the National Ocean Survey at an open coastal location on Bermuda to provide instantaneous sea surface height determinations during Seasat overflights of the island Because the tide gage was geodetically tied to the laser tracking station on Bermuda, the satellite's position relative to the sea surface could be determined independently for comparison with altimeter measurements. A root sum square error of 4.0 cm in the laser's vertical position determination, relative to the sea surface, has been estimated apart from possible errors arising from the present lack of precise information on the elevation of the Bermuda geoid. O.C.

AN EMPIRICAL DETERMINATION OF THE EFFECTS OF SEA STATE BIAS ON SEASAT ALTIMETRY

G. H. BORN, M A. RICHARDS (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA), and G. ROSBOROUGH (Texas, University, Austin, TX) Journa Journal of Geophysical Research, vol. 87, Apr 30, 1982, p 3221-3226. NASA-supported research. refs

A linear empirical model has been developed for the correction of sea state bias effects, in Seasat altimetry data altitude measurements, that are due to (1) electromagnetic bias caused by the fact that ocean wave troughs reflect the altimeter signal more strongly than the crests, shifting the apparent mean sea level toward the wave troughs, and (2) an independent instrument-related bias resulting from the inability of height corrections applied in the ground processor to compensate for simplifying assumptions made for the processor aboard Seasat After applying appropriate corrections to the altimetry data, an empirical model for the sea state bias is obtained by differencing significant wave height and height measurements from coincident ground tracks Height differences are minimized by solving for the coefficient of a linear relationship between height differences and wave height differences that minimize the height differences. In more than 50% of the 36 cases examined, 7% of the value of significant wave height should be subtracted for sea state bias correction. OC.

SEA-STATE-RELATED ALTITUDE ERRORS IN THE SEASAT **RADAR ALTIMETER**

G S HAYNE and D. W. HANCOCK, III (NASA, Wallops Flight Center, Wallops Island, VA) Journal of Geophysical Research, vol. 87, Apr. 30, 1982, p. 3227-3231 refs

A significant waveheight-dependent bias is identified in Seasat-measured surface heights which cannot be neglected when using Seasat data at accuracies within 10 cm. Ten-second averages of the data from 63 waveform sampling rates in the Seasat radar altimeter were least squares fitted with a six-parameter model, the time-origin parameter of which provides a measure of the position of the actual mean radar waveform relative to the sampling rate and therefore provides altitude measurement corrections. Attention is given to actual altimeter point target response function, waveform sampler noise baseline, waveform sampler gain calibration, attitude angle and sea surface skewness, as effects not accounted for in Seasat altimeter measurements and standard data processing OC

SEASAT ALTIMETER TIMING BIAS ESTIMATION

J G MARSH (NASA, Goddard Space Flight Center, Geodynamics Branch, Greenbelt, MD) and R G WILLIAMSON (EG & G Washington Analytical Services Center, Inc., Riverdale, MD) Journal of Geophysical Research, vol. 87, Apr 30, 1982, p 3232-3238. refs

A technique developed for the solution of time lag bias based on the analysis of sea surface height discrepancies at ground track intersections, prompted by the presence of a time calibration bias in Seasat altimeter data that produced measurement errors in excess of 1 m, is shown to yield a separation of the dominant, once-per-revolution ephemeris error amounting to about 1.5 m rms from the timing error signature. The technique does not depend on precise geoid data, and in application to a global Seasat altimeter data set covering July 28-August 9, 1978, has yielded a time lag value of -81.0 + or - 2 msec This corroborates the -79.4 msec revised value derived from a reexamination of internal instrument time delays. OC.

EVALUATION OF THE SEASAT ALTIMETER TIME TAG BIAS

B E. SCHUTZ, B D. TAPLEY, and C. SHUM (Texas, University, Austin, TX) Journal of Geophysical Research, vol. 87, Apr. 30, 1982, p. 3239-3245 refs

(Contract NOAA-MO-A01-78-00-4325, JPL-954703)

Two methods were used in analyses of Seasat altimeter data, aimed at the corroboration of an inherent altimeter microprocessor delay compensation value of -79.4 msec, which benefited from a global data distribution in the oceanic areas: (1) the crossover method, using altimeter data differenced at points where the Seasat ground track intersected with itself, and (2) the direct use of the altimeter data Because the former method is independent of errors in the geoid model, it is considered the more reliable. For all crossover method results, the adopted value of -79.4 msec is within the bounds of the standard deviation associated with the estimates, of which -78.1 + or - 2.0 msec is considered the best representative 00

WAVEHEIGHT AND WIND SPEED MEASUREMENTS FROM THE SEASAT RADAR ALTIMETER

L S. FEDOR (NOAA, Wave Propagation Laboratory, Boulder, CO) and G. S BROWN (Applied Science Associates, Inc., Apex, NC) Journal of Geophysical Research, vol 87, Apr 30, 1982, p. 3254-3260 refs

(Contract NOAA-NA-79SAC00723)

A similarity to the results of earlier comparisons with the GEOS-3 radar altimeter data is noted, in the mean difference of -0.25 m/sec and standard deviation of 158 m/sec found upon comparison of Seasat radar altimeter-derived winds with buoy-recorded winds in the 1-10 m/sec range. It has therefore been demonstrated by means of two different radars and data sets that radar altimetry can provide accurate estimates of ocean surface wind speeds. Although the altimeter cannot provide the large-swath coverage provided by the Seasat scatterometer, its ability to produce accurate, simultaneous estimates of wind speed and waveheight may be important to future oceanographic research O.C

R. L BERNSTEIN, R. H WHRITNER (California, University, La Jolla, CA), and G H. BORN (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA) Journal of Geophysical Research, vol. 87, Apr. 30, 1982, p. 3261-3268. refs (Contract NAS7-100)

An experiment conducted in the Kuroshio Current, east of Japan, has confirmed the ability of radar altimeters of precision on the order of 10 cm, such as that of the Seasat satellite, to measure the small oceanic height variations associated with geostrophic ocean currents Changes in surface dynamic height were inferred from data gathered by air-expendable barithermographs, which had been dropped to coincide with the Seasat subtrack, for the periods between the flights of September 25 and October 5 and 13, 1978. The changes registered generally agreed to within + or - 10 cm of the height changes observed in the altimeter data. O.C. THE SEASAT ALTIMETER MEAN SEA SURFACE MODEL

J. G. MARSH (NASA, Goddard Space Flight Center, Geodynamics Branch, Greenbelt, MD) and T. V. MARTIN (EG & G Washington Analytical Services Center, Inc., Riverdale, MD) Journal of Geophysical Research, vol 87, Apr. 30, 1982, p. 3269-3280. refs

Gridding techniques are used to combine an 18-day set of Seasat altimeter data and two precisely-computed Seasat ephemerides, in order to arrive at global contour maps of the mean sea surface topography The altimeter data have an rms agreement of 111 cm with the SS3 mean sea surface computed by means of the PGS-S3 ephemerides, and of 70 cm with the SS4 mean surface derived from the PGS-S4 ephemerides. While comparisons with the GEM 10B 1 x 1 deg gravimetric geoid have yielded rms differences of 2.8 m, those with a global mean sea surface derived from GEOS 3 altimeter data show rms differences of 1.3 m and 1.1 m for the cases of the SS3 and SS4 surfaces. respectively. An SS4 mean sea surface topograph is featured among the study findings presented Further improvements in the representation of mean sea surface topography are expected with the development of more accurate gravity models for orbit computation. 00

WENTZ (Remote Sensing Systems, Inc., Sausalito, CA) Journal of Geophysical Research, vol. 87, Apr. 30, 1982, p. 3297-3317. refs

A description is given of the algorithm used to convert Seasat-A satellite microwave scatterometer measurements of ocean normalized radar cross section to the neutral stability vector wind at 195 m height, as well as to compare these winds with high-quality surface observations. The wind vector algorithm used an empirical normalized radar cross section model function to describe the ocean normalized radar cross section's dependence on the 19.5-m neutral stability wind vector. In addition, two model functions were evaluated by means of an independent set of in situ surface wind observations from the Joint Air Sea Interaction experiment (JASIN). Better results were produced by these comparisons than the stipulated Seasat wind speed and direction accuracy specifications of + or -2 m/sec and + or -20 deg, respectively, over the 0-16 m/sec range of winds observed during JASIN O.C.

R. K MOORE, I J BIRRER (University of Kansas Center for Research, Inc., Lawrence, KS), E. M. BRACALENTE (NASA, Langley Research Center, Hampton, VA), G J. DOME (Bell Telephone Laboratories, Inc., Holmdel, NJ), and F J. WENTZ (Remote Sensing Systems, Inc., Sausalito, CA) Journal of Geophysical Research, vol 87, Apr. 30, 1982, p 3337-3354. refs

The effect of attenuation in precipitation regions of the sea, which must be considered in order to measure the radar backscatter from the ocean with sufficient accuracy to allow determination of the wind vector, can be ascertained from a knowledge of the brightness temperature observed by a microwave radiometer such as the Seasat multifrequency scanning radiometer. Two algorithms relating radiometric measurements and attenuation, and thereby correcting measured scattering coefficient values, were compared with wind vectors reported by surface observers and those determined by the Seasat scatterometer measurements with and without correction for atmospheric attenuation. Although the attenuation correction yields some improvements, it is constrained by both radiometer footprint differences and different scan patterns.

A82-29619* Washington Univ., Seattle. SURFACE WIND ANALYSES FOR SEASAT

PIERSON (City College, New York, NY), S. PETEHERYCH (Department of the Environment, Atmospheric Environment Service, Downsview, Ontario, Canada), J. C WILKERSON (NOAA, Camp Springs, MD), P M. WOICESHYN (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA), and M WURTELE (California, University, Los Angeles, CA) Journal of Geophysical Research, vol. 87, Apr. 30, 1982, p. 3355-3364. refs

During the 99 days of Seasat operation, two large-scale experiments were conducted which established the satellite sensors' wind measuring capabilities: (1) the Gulf of Alaska Experiment (GOASEX), and (2) the Joint Air Sea Interaction Experiment (JASIN), which unlike GOASEX was independent of the Seasat program and undertook comprehensive air and sea investigations which furnished excellent comparison data for Seasat. Qualitative comparison windfields were also provided by several storms. The point measurements in GOASEX and JASIN were averaged in conjunction with Seasat scatterometer regions and, on the basis of comparisons between several anemometers on buoys and meteorological ships and the calculation of various averaging times, a 20-min average yields a scatterometer scale windfield accuracy of up to + or 1 m/sec and + or - 10 deg in Ŏ.C. well-behaved windfields.

(Contract NAS1-16032; NAS7-100)

The operational theory, control algorithms, and comparisons with surface-determined wind speeds for the scatterometer (SASS), altimeter (ALT), and passive microwave radiometer (SMMR) on board the Seasat satellite are presented. Radiative scattering combining specular reflections and Bragg resonance scattering are noted to occur at tilting waves and sea foam, two conditions highly correlated with wind speed. SASS scans swaths of 70, 200, and 700 km from nadir, the SMMR covers a 150 km strip. Normalized radar sections are derived from the SASS and ALT telemetry, and brightness temperature from the SMMR ALT winds were found to be biased about 3 m/sec low, while intercomparison between the SMMR and SASS data showed a mean difference of 0.3 m/sec with a standard deviation from measured winds of 1.7 m/sec or less. The effects of land thermal emissions, rain, and sun glint are discussed, and good viewing conditions are concluded to result in 2 m/sec accuracy MSK

(Contract NAS7-100)

Improved geophysical algorithms are shown to be able to determine sea surface temperature (SST) to an accuracy of 1 C (1 sigma) under favorable surface and atmospheric conditions over an SST range of 10-30 C. Under similar conditions, the radiometer wind retrievals track the scatterometer winds within a scatter of 2 m/s (1 sigma) over a wind speed range of 0-25 m/s These conditions require that contamination from land, rain, sun glint, and radio frequency interference be avoided What is more, water vapor determinations in the midlatitudes and in the tropical Pacific are found to agree with estimates of precipitable water from radiosondes to within 10%.

THE OBSERVATION OF OCEAN SURFACE PHENOMENA USING IMAGERY FROM THE SEASAT SYNTHETIC APERTURE RADAR - AN ASSESSMENT

J. F VESECKY (Stanford University, Stanford, CA) and R. H STEWART (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, California, University, La Jolla, CA) Journal of Geophysical Research, vol. 87, Apr 30, 1982, p. 3397-3430. refs

(Contract N00014-75-C-0356; NOAA-MO-A01-78-00-4318)

The principles governing synthetic aperture radar (SAR) and its use on the Seasat spacecraft are reviewed. The way in which wind stress, surface currents, long gravity waves, and surface films modulate the scattering properties of resonant (approximately 30-cm-wavelength) waves is discussed, with particular emphasis placed on the mechanisms that could produce images of long gravity waves. Doppler effects by ocean motion are also described. Measurements of long (wavelength more than about 100 m) gravity waves made using Seasat SAR imagery are compared with surface measurements during several experiments. Combining these results, it is found that dominant wavelength and direction are measured by Seasat SAR within + or - 12% and + or - 15 deg, respectively. It is noted, however, that ocean waves are not always visible in SAR images, and detection criteria are discussed in terms of wave height, length, and direction. C.R. SEASAT WIND AND WAVE OBSERVATIONS OF NORTHEAST PACIFIC HURRICANE IVA, AUGUST 13, 1978

F. I. GONZALEZ (NOAA, Pacific Marine Environmental Laboratory, Seattle, WA), T. W. THOMPSON (Science Applications, Inc., Planetary Science Institute, Pasadena, CA), W. E BROWN, JR. (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA), and D. E WEISSMAN (Hofstra University, Hempstead, NY) Journal of Geophysical Research, vol 87, Apr. 30, 1982, p. 3431-3438 NOAA-supported research refs (Contract NAS7-100)

The paper examines Seasat wind and wave observations collected in the eye of hurricane Iva on August 13, 1978 in the northeast Pacific. A maximum wind speed of 25-30 m/s is observed, along with a banana-shape high-wind-speed distribution. Two-dimensional Fourier transforms of selected SAR scenes show a dominant wavefield characterized by wavelengths of 166-211 m, with a fanlike distribution of propagation directions. A simple geometric model is proposed to explain the dominant wave field in terms of prior storm intensity and location, which is combined with the Ross parametric hurricane wave model and Seasat wind and wave data to estimate a value of 43 km for the effective radial distance from the storm center to the region of maximum winds.

A STUDY OF THE EARTH'S RADIATION BUDGET USING A GENERAL CIRCULATION MODEL

J. M. SLINGO (Meteorological Office, Bracknell, Berks., England) Royal Meteorological Society, Quarterly Journal, vol. 108, Apr. 1982, p 379-405. refs

A model clarifying the roles played by clouds and the surface in determining the seasonal variations in the radiation budget is described. The model employs an interactive radiation scheme with seasonally varying climatological sea surface temperatures, incoming solar radiation, and zonal mean climatological cloud amounts. Since its simulation of the various components of the earth's radiation compares favorably with results from satellites, its results are used in explaining certain aspects of the observed budgets. The model results are also used to estimate the earth's annual mean total energy budget and, in particular, the poleward flux of heat by the oceans. The oceanic heat flux implied by the model compares favorably with estimates based on observations, the main differences being at the equator and near the North Pole. C.R.

EMISSIVITY AND REFLECTANCE OF THE MODEL SEA SURFACE FOR THE USE OF AVHRR DATA OF NOAA SATELLITES

T. TAKASHIMA and Y. TAKAYAMA (Meteorological Research Institute, Tsukuba, Ibaraki, Japan) Papers in Meteorology and Geophysics, vol. 32, Dec. 1981, p. 267-274.

The emissivity and reflectance of the sea surface, modeled from AVHRR advanced radiometer sensing from the NOAA-6 satellites, are derived as a function of the incident and emergent directions of radiation. The sea surface is modeled numerically with slope components varying according to a gaussian distribution, including isotropy if independent of the wind direction, and anisotropy if dependent on the wind direction. The geometry of the slope with changing incident and reflecting angles is formulated in terms of spherical trigonometry. Treatment of the surface as a specular reflector is found to be acceptable except for visible light, where the reflection depends on the surface characteristics and a bivariate gaussian analysis is necessary. Additional influences due to oil slicks are considered, particularly for reflectance reduction. M.S.K

RETRIEVAL OF OCEAN SURFACE AND ATMOSPHERIC PARAMETERS FROM MULTICHANNEL MICROWAVE RADIOMETRIC MEASUREMENTS

A. T. C. CHANG (NASA, Goddard Space Flight Center, Earth Survey Application Div., Greenbelt, MD) and A. S. MILMAN (Systems and Applied Sciences Corp., Riverdale, MD) IEEE Transactions on Geoscience and Remote Sensing, vol GE-20, Apr. 1982, p. 217-224. refs

Methods for the retrieval of ocean surface temperature, surface wind speed, rain rate, cloud height, and the amounts of water vapor and nonprecipitated liquid water over the ocean from Scanning Multichannel Microwave Radiometer (SMMR) data are presented. The sensitivity of retrieval algorithms for wind speed and sea surface temperature, in the absence of rain, to the undetected presence of rain, is discussed along with the accuracy of a more general method for the retrieval of rain rate in conjunction with other meteorological parameters. It is concluded that the inability to retrieve the average rain rate accurately at small rain angles is due to the inability of SMMR to distinguish between small raindrops and nonprecipitating droplets. LASER-INDUCED BIOLUMINESCENCE

G. D. HICKMAN (Applied Science Technology, Inc., Arlington, VA) and R. V. LYNCH, III (U.S. Navy, Naval Research Laboratory, Washington, DC) In Los Alamos Conference on Optics '81, 2nd, Los Alamos, NM, April 7-10, 1981, Proceedings. Bellingham, WA, SPIE - The International Society for Optical Engineering, 1981, p. 263-268. refs

(Contract N00014-80-C-0673)

A project has been initiated to determine the feasibility of developing a complete airborne remote sensing system for rapidly mapping high concentration patches of bioluminescent organisms in the world's oceans. Conceptually, this system would be composed of a laser illuminator to induce bioluminescence and a low light level image intensifier for detection of light. Initial laboratory measurements consisted of using a 2-J flash lamp pulsed optical dye laser to excite bioluminescence in the marine dinoflagellate Pyrocustis lunula at ambient temperature using Rhodamine 6G as the lasing dye (585 nm) and a laser pulse width of 1 microsec. After a latency period of 15-20 msec, the bioluminescence maximum occurred in the blue (480 nm is the wavelength maximum for most dinoflagellate bioluminescence) with the peaking occurring approximately 65 msec after the laser pulse Planned experiments will investigate the effect of different excitation wavelengths and energies at various temperatures and salinities of the cultures.

A SHIP AND SATELLITE VIEW OF HYDROGRAPHIC FEATURES IN THE WESTERN GULF OF MEXICO

D. A. BROOKS (Texas A & M University, College Station, TX) and R. V LEGECKIS (Texas A & M University, College Station, TX; NOAA National Earth Satellite Service, Washington, DC) Journal of Geophysical Research, vol. 87, May 20, 1982, p. 4195-4206. refs

(Contract NSF OCE-79-24606; NSF OCE-78-22481)

In April 1980, nearly synoptic hydrographic observations were obtained in the western Gulf of Mexico by satellite and ship. A meandering surface thermal front which turned northeastward from the Mexican coast near 23 deg N was prominent in the satellite infrared observations. The front separated a southern anticyclone and a northern cyclone, both of which had horizontal scales of several 100 km and were prominent in the subsurface hydrographic observations. The eastward geostrophic volume transport in the confluent leg of the two features was roughly equal to that of the Florida Current. A shallow layer of fresh, cool water from the Texas shelf region extended about 300 km seaward into the cyclone

along the northern side of the front. Remnant Subtropical Underwater in the core of the April anticyclone indicates its origin in the eastern Gulf Loop Current (Author)

ON THE SYNTHETIC APERTURE RADAR IMAGING OF OCEAN SURFACE WAVES

A. V. IVANOV (Akademila Nauk SSSR, Institut Radiotekhniki i Elektroniki, Moscow, USSR) IEEE Journal of Oceanic Engineering, vol. OE-7, Apr. 1982, p. 96-103. refs

A process of synthetic aperture radar imaging of ocean surface waves is considered on the basis of the two-scale model of microwave scattering by a disturbed sea surface. Analytical expressions are obtained to relate characteristics of a large-scale wave image, averaged over an ensemble of realizations of the small-scale ripple, with the wave, radar, and viewing scheme as parameters. It is shown that the wave image would be defocused as an image of a target moving in the along-track direction with a speed equal to a half of the wave phase speed projection on the line of flight. The defocusing magnitude was measured experimentally for the ocean swells images, obtained with an airborne S-band radar, and the results are found to be in satisfactory agreement with the model prediction (Author)

INFRARED SENSING OF SEA SURFACE TEMPERATURE FROM SPACE

M SIDRAN (Bernard Baruch College, New York, NY) Remote Sensing of Environment, vol. 10, Sept 1980, p. 101-114. refs

The retrieval of sea surface temperature information from the infrared signals received by remote sensing satellites is examined. Factors influencing the received signal are evaluated, including surface emissivity, spectral radiance, atmospheric transmittance, and sources of error in lengthy computer retrievals based on the integration of the radiative transfer equation related to imperfections in atmospheric transmittance models, uncertainties in the vertical profiles of atmospheric pressure, temperature and humidity profiles, temperature discontinuities at the air-sea interface, differences between surface and bulk water temperatures and the neglect of surface emissivity and reflectance are pointed out. The simple retrieval scheme of Prabhakara et al. (1974), which makes use of three spectral bands to achieve an rms error of + or - 1.1 K, is then reviewed, and a simplified version of this scheme based on only two bands is presented which reduces the rms error to + or A.L.W. - 1.0 K

NEARSHORE CURRENT PATTERN OFF SOUTH TEXAS - AN INTERPRETATION FROM AERIAL PHOTOGRAPHS

R. E. HUNTER and G. W. HILL (U.S. Geological Survey, Menlo Park, CA) Remote Sensing of Environment, vol. 10, Sept. 1980, p. 115-134 refs

Turbidity patterns seen on aerial photographs of nearshore waters are analyzed to derive the current patterns in a 4-km wide zone along the south Texas coast. Series of color aerial photographs were taken vertically from an altitude of 3700 m on December 23, 1968, following the passage of a cold front

05 OCEANOGRAPHY AND MARINE RESOURCES

accompanied by strong northwesterly to northeasterly winds. Examination of photographs taken from 6 to 80 min apart indicate the presence of southward currents nearly parallel to the shore, with velocities increasing from about 17 cm/sec off shore to about 40 cm/sec at the line of breaking waves Rip-current plumes were observed to drift with the longshore current and be deformed by the horizontal shear. The turbidity by which these currents were traced originated in Aransas pass, a tidal inlet connecting several estuarine bays to the Gulf of Mexico, and a preceding ebb-tidal plume from the same inlet A linear pattern of turbid and less turbid bands also suggests the development of Langmur circulation with cell axes parallel to the shelf current. MEASURING SEA SURFACE TEMPERATURE FROM SATELLITES - A GROUND TRUTH APPROACH

D. C. MCCONAGHY (NOAA, Southwest Fisheries Center, La Jolla, CA) Remote Sensing of Environment, vol 10, Dec. 1980, p 307-310.

Determining the correction for atmospheric attenuation is a major problem in processing thermal infrared digital data from very high resolution radiometers aboard NOAA Polar Orbiting Satellites. An empirical equation for estimating this correction is developed. The coefficients of the equation are determined by using regression techniques and comparing satellite observations to sea surface temperature measurements. Although there is not sufficient data to fully evaluate this procedure, initial satellite measurements are within 0.5 C of independent sea surface temperature measurements (Author)

COASTAL ENVIRONMENT CHANGE ANALYSIS BY LANDSAT MSS DATA

J -K. HONG (Tokyo University of Agriculture and Technology, Tokyo, Japan) and J. IISAKA (IBM Japan, Ltd., Tokyo, Japan) Remote Sensing of Environment, vol. 12, May 1982, p. 107-116 refs

A case study of coastal environmental change is conducted using computer-assisted analysis of Landsat scenes for three different years The Kanto area in Japan is divided into three study areas on the basis of social and geographical factors Land use changes along the bay from November 26, 1972, to November 11, 1980, are studied and the results are interpreted by referring to the ground truth data. The results show a continuous decrease in the area of shallow water along the bay and changes in land use in the coastal areas. The changes are recognized as being closely related to the bay area changes; they are found to correspond well to differences in social developments in the study areas. Landsat data are thus shown to provide sufficient information on the environmental changes taking place. C.R

ESTIMATION OF THE TEMPERATURE OF THE UPPER BOUNDARY OF CLOUD COVER OVER THE WORLD OCEAN [OTSENKA TEMPERATURY VERKHNEI GRANITSY OBLACHNOSTI NAD MIROVYM OKEANOM]

O. AVASTE, O. KIARNER, and S. KEEVALLIK (Akademila Nauk Estonskoi SSR, Institut Astrofiziki i Fiziki Atmosfery, Tartu, Estonian SSR) Meteorologila i Gidrologila, June 1982, p. 54-59. In Russian refs

The temperature of the upper boundary of cloud cover over the world ocean is estimated on the basis of cloud-amount estimates made by Avaste et al. (1981), climatological means of ocean surface temperature, and mean monthly values of outgoing radiation fluxes. Mean monthly upper-cloud-boundary temperatures over the world ocean are estimated for the 30 deg N to 30 deg S latitude belt Data from the Nimbus-3 and NOAA meteorological satellites were used in the estimation. INTERANNUAL VARIATIONS OF OUTGOING IR ASSOCIATED WITH TROPICAL CIRCULATION CHANGES DURING 1974-1978

B. LIEBMANN and D. L. HARTMANN (Washington, University, Seattle, WA) Journal of the Atmospheric Sciences, vol. 39, May 1982, p. 1153-1162. refs

(Contract NSF 78-07369; NSF 81-06099)

Interannual variability of outgoing IR in the tropical Pacific Ocean is studied using measurements derived from the NOAA scanning radiometer In addition to the usual mean maps, seasonal anomaly maps are constructed from June, July, August 1974-December 1977, and January, February 1978. Time series representing the equatorial eastern Pacific sea-surface temperature (SST) anomalies and monthly anomalies at various locations are also plotted During this period a warming event occurs, in which SSTs in the eastern Pacific rapidly become anomalously warm. Dramatic changes in outgoing IR occur simultaneously with this SST increase. The region of convergence over Indonesia shifts eastward and connects to a well-developed intertropical convergence zone (ITCZ). The South Pacific convergence zone, but develops more slowly and does not reach its maximum strength until more than a year after the SST increases occur. By this time the ITCZ has returned to its prewarming state. Eastward movement of the SPCZ is also apparent (Author)

ESTIMATION OF THE PRECIPITABLE WATER FROM THE IR CHANNEL OF THE GEOSTATIONARY SATELLITE

T AOKI (Meteorological Satellite Center, Kiyose, Tokyo, Japan) and T INOUE (Meteorological Research Institute, Yatabe, Ibaraki, Japan) Remote Sensing of Environment, vol. 12, July 1982, p 219-228. refs

It has been shown that over the tropical oceans the total precipitable water can be estimated from the infrared radiometer data (10 5-12.5 microns) of the Geostationary Meteorological Satellite. The satellite derived values are in good agreement with the radiosonde data, with a 0.53 g/sq cm rms difference The weekly mean distribution of the precipitable water over the tropical ocean of western Pacific has been obtained in both summer and winter seasons. The pattern of this distribution is in reasonable agreement with other authors and climatological data. (Author)

PULSE-TO-PULSE CORRELATION IN SATELLITE RADAR ALTIMETERS

E. J. WALSH (NASA, Wallops Flight Center, Wallops Island, VA) Radio Science, vol. 17, July-Aug. 1982, p. 786-800 refs

Pulse-to-pulse correlation in satellite radar altimeters is examined to determine if range jitter in future altimeters could be reduced by increasing the pulse repetition frequency (PRF) Data from the Skylab radar altimeter is analyzed and compared with rules of thumb and the results of a Monte Carlo simulation Altimeter range tracker configurations are reviewed and a simple curve is developed for the PRF below which decorrelation is assured. An adaptive PRF for future altimeters is recommended to conserve mission power while optimizing data collection during high-sea states. (Author)

A QUANTITATIVE MULTISPECTRAL ANALYSIS SYSTEM FOR AERIAL PHOTOGRAPHS APPLIED TO COASTAL PLANNING

C. VALERIO (Aix-en-Provence, Centre d'Etudes Techniques de l'Equipement, Les Milles, Bouches-du-Rhone, France) and A LLEBARIA (CNRS, Laboratoire d'Astronomie Spatiale, Marseille, France) International Journal of Remote Sensing, vol 3, Apr.-June 1982, p. 181-197. refs

A system that may be used to study the dispersion of effluents in the sea either by means of their color or by using a fluorescent tracer, rhodamine B, is described, and its use is illustrated with the study of the dispersion over one day of a release of rhodamine in seawater. The underlying principle is the adjustment of the data acquisition device to the optical properties of the phenomenon being studied, so that the signal-to-noise ratio is optimized A very accurate digitizing microdensitometer is used, and the data processing system is adapted to allow for correction of radiometric, and temporal variations. A simple mathematical spatial. representation of the interaction of sunlight with the environments encountered before reaching the negative is employed. An experimental procedure that eliminates the need for sampling from boats is used to follow the evolution of the plume, giving maps showing quantity of rhodamine to an accuracy of about five percent. ANALYSIS OF OCEAN COLOR SCANNER DATA FROM THE SUPERFLUX III EXPERIMENT

C. W. OHLHORST Mar 1982 30 p refs

(NASA-TM-83290, NAS 1.15 83290) Avail NTIS HC A03/MF A01 CSCL 08J

The scanner collected data on October 15, 20, and 22, 1980. Single-channel gray-scale data products generated 5 minutes after the scanner were collected and showed details of the Chesapeake plume structure, suggesting that this quick-look capability could have potential use for experiments in real time. The Chesapeake Bay plume extended offshore about 5 nautical miles on October 15, and 7 nautical miles on October 20. Using the October 15 1980, data, a correlation coefficient of r = 0.889 was obtained between chlorophyll 'A' and the ratio of band 7 (664-684 nanometers) to band 9 (746-766 nanometers). This ratio was then used to calculate the average surface chlorophyll 'A' concentration of the water flowing out of the Chesapeak Bay. A ratio from the Ocean Color Scanner bands was created to simulate the ratio that the Multichannel Ocean Color Sensor uses to calculate chlorophyll A concentrations Using the October 15, 1980, data set, this ratio has a correlation coefficient of r = -0.739 with the log of the chlorophyll 'A' and the ratio of band 2 minus band 4 to band 2 plus band 4 of the Ocean Color Scanner No correlation is found between the Ocean Color Scanner data and total suspended solid measurements made on October 15, 1980.

W. L. PHYSICK and G B. TUCKER In WMO Intern. Conf. on Early Results of FGGE and Large-Scale Aspects of its Monsoon Apr. 1981 refs Expt. 5 p

Avail NTIS MF A01; HC WMO

Drifting buoy recordings of mean sea level pressure (MSLP) are assessed as a means for investigating climate. Data from FGGE buoys were compared to long term MSLP's computed from daily numerical analyses and MSLP's from nine weather stations. Pressures observed in high latitude oceans during FGGE are lower than average for every month. The maximum difference is 12 mb. The MSLP is significantly different from normal. Mean zonal winds at 500 mb are significantly stronger by up to 50%. Buoys are useful data sources, but because the data is anomalous, they should not be used as reference points Author (ESA)

REPRESENTATIVENESS OF CLOUD MOTION WINDS DEDUCED FROM GOES INDIAN OCEAN SATELLITE IMAGERY FOR THE DESCRIPTION OF THE INDIAN SUMMER MONSOON

M. DESBOIS In WMO Intern. Conf. on Early Results of FGGE and Large-Scale Aspects of its Monsoon Expt 5 p Apr. 1981 refs

Avail. NTIS MF A01; HC WMO

A technique which extracts wind fields from cloud motions is described and data thus produced are compared with cloud winds extracted by standard methods, dropsondes and balloon winds of the BALSAMINE experiment. A set of successive pictures is presented in loops. Each picture can be moved relative to the others. Pictures are aligned using landmarks and cloud motions are measured by moving the pictures so that the observed cloud appears motionless during the loop. The relative displacement of the pictures and the location of the cloud elements are recorded and the results are processed on a computer that plots them on a map It takes 4 hr to obtain a field Results compare well with other methods and indicate that low cloud tracers follow the wind like constant level balloons. Over the Indian Ocean low cloud winds are representative of the 900-850 mb layer. Cloud winds are advocated as a tool for investigating monsoons

J. PAEGLE (Utah Univ.) *In* WMO Intern. Conf. on Early Results of FGGE and Large-Scale Aspects of its Monsoon Expt. 9 p Apr. 1981 refs

Avail: NTIS MF A01; HC WMO

The FGGE 3 b analyses and NOAA satellite data are used to delineate periods of intense convective activity over the central and western Pacific Ocean For periods of stronger convection, the transient kinetic energy is relatively stronger over the deep tropics and into the subtropics than for times of less active tropical overturnings. Regions which are predominantly convective correspond to areas where the balance equation is nonelliptic. For these areas only steady states which are strongly divergent and with small or vanishing absolute vorticity are possible. Correlations of upper level outflows with wind components suggest substantial influence of the tropics upon the subtropics in time scales of 3 days. The need to include tropical processes in numerical weather prediction for tropical and subtropical numerical weather prediction is shown.

IMPACT OF ADDITIONAL SUMMER MONEX WIND DATA ON THE PREDICTION OF MONSOON DEPRESSIONS DURING JUNE -AUGUST 1979 WITH TWO VERSIONS OF PRIMITIVE EQUATION (PE) BAROTROPIC MODEL

D. R. SIKKA, S. SINHA, S. S. SINGH, P. L KULKANNI, and A A. KULKARNI *In* WMO Intern. Conf. on Early Results of FGGE and Large-Scale Aspects of its Monsoon Expt 4 p Apr. 1981 refs Sponsored in part by Colorado State Univ.

Avail NTIS MF A01, HC WMO

The reliability of barotropic prediction and the influence of MONEX data was investigated Streamlines and isotachs data for 700 mb are analyzed using (1) regular weather station observations and (2) additional data from Monex platforms. Two versions of the P.E. barotropic model, which differ only in the dynamic initialization procedure, are used and it is found that they perform equally well. They perform best on those structures in which the easterly flow is of comparable strength to monsoon westerlies at 700 mb The impact of additional data is not positive consistently because the easterlies around the depression are weaker than westerlies and the additional data are better defined the westerly maxima. Westward motion of monsoon depression is linked with the convergence ahead of the system and the preferential convection in the forward sector. It is concluded that the P.E. barotropic model is not the best one to study the impact of additional data. Author (ESA)

MONEX OCEANOGRAPHIC OBSERVATIONS ALONG THE EAST AFRICAN COAST

O. B. BROWN and F SCHOTT *In* WMO Intern. Conf on Early Results of FGGE and Large-Scale Aspects of its Monsoon Expt. 16 p Apr. 1981 refs

Avail: NTIS MF A01; HC WMO

Ship, buoy, and satellite current, temperature and air pressure data were used in order to study the Somali current. Wind field development, near surface circulation and upwelling were noted Temperature, salinity, and potential density were recorded. The salinity profiles show several layers which deviate by more than 0.1 ppt from the mean. The density profile is smooth So-called anomalous flow and expected flow often occur in the same year. Results suggest a mesoscale ocean-atmosphere interaction driven by the large horizontal difference in ocean surface temperature along the East African coast. Author (ESA)

ON THE SPACE-TIME VARIABILITY OF OCEAN SURFACE MIXED LAYER CHARACTERISTICS OF CENTRAL AND EASTERN ARABIAN SEA DURING MONSOON-77

R R RAO, P. G. K. MURTY, M G JOSEPH, and K. V. S RAMAN *In* WMO Intern. Conf. on Early Results of FGGE and Large-Scale Aspects of its Monsoon Expt. 8 p Apr 1981 refs

Avail NTIS MF A01; HC WMO

Surface mixed layer deepening and cooling of the Arabian Sea, which occurs in a nonhomogeneous manner during the monsoon season, is described. Ship polygons collected data on mixed layer (MLD) characteristics Average MLD and vertical temperature gradient below MLD were recorded spatially and temporally. Deepening and cooling rates are higher over the central Arabian Sea than over the eastern Arabian Sea. In the central Arabian sea, deepening is greatest at the northern end. In the eastern Arabian Sea the layer deepening is higher at the southern location. The observed deepening shows good agreement with the computed layer depth, considering convective turnover caused by surface cooling. However, wind induced mixing contributes to the observed layer depth more in Phase-1U than Phase-2U. Vertical flow at the base of the mixed layer is upward, causing entrainment of colder waters from the upper thermocline and leading to mixed layer deepening and cooling Author (ESA)

ESTIMATES OF SEA SURFACE STRESS FOR SUMMER MONEX FROM CLOUD MOTIONS

B B HINTON and D. P WYLIE *In* WMO Intern. Conf. on Early Results of FGGE and Large-Scale Aspects of its Monsoon Expt. 5 p Apr. 1981 refs

(Contract NSF ATM-79-13097)

Àvail NTIS MF A01; HC WMO

Numerical modeling of surface wind stress is described. Satellite winds, cloud motions and monthly ship data are analyzed Cloud motion speed is plotted as a function of the speed measured by a collocated ship. A regression line extrapolates speed from cloud to ship level Regression relations are exploited for direction changes, e.g. veering. Cloud and ship data are merged in order to produce daily stress maps. Results agree with observed published data. The method is accurate over a wide area, at a 2 deg or more resolution, for several days. Cross correlations indicate that gridded cloud motion measurements error characteristics are compatable with ship wind measurements Author (ESA)

MARINE BOUNDARY LAYER WIND STRUCTURE OVER THE BAY OF BENGAL DURING MONEX-79

S. SETHURAMAN *In* WMO Intern. Conf. on Early Results of FGGE and Large-Scale Aspects of its Monsoon Expt 7 p Apr 1981 refs Sponsored by NSF

Avail: NTIS MF A01; HC WMO

The role of the atmospheric boundary layer in monsoon formation was investigated through a micrometeorological tower which observed turbulent fluxes of heat and momentum over the ocean, a weather station that continuously recorded mean parameters, and pilot balloon observations to a height of 1 km Wind profiles and surface/layer fluxes of momentum and heat indicate a change in the direction of the heat flux (in a vertical plane). Surface heat flux is upward with small values for cases with large downward heat fluxes in the upper layers. This occurs when the monsoon trough is far northward causing a break in the monsoon When the trough moves to its normal position, there is a strong convective boundary layer over the Bay of Bengal

ANALYSIS OF OCEAN AND ATMOSPHERE THERMODYNAMICAL CHARACTERISTICS DURING THE ONSET OF SOUTHWEST MONSOON OVER THE ARABIAN SEA

P. V. NUZHDIN *In* WMO Intern Conf on Early Results of FGGE and Large-Scale Aspects of its Monsoon Expt. 2 p Apr. 1981

Avail: NTIS MF A01; HC WMO

Ship surface and oceanographic data are used to analyze the onset of the Arabian Sea monsoon. Areas of marked heat storage, such as the central Arabian Sea are treated as centers of air sea coupling. A positive enthalpy anomaly is formed in this area from April to June, together with the Somali current, determines monsoon intensity. Enthalpy (H) and potential energy (Ep) were computed for the ocean layers 0 to 100 and 0 to 500 m as well as latent neat and sensible heat fluxes in the surface atmospheric layer over the ocean. The difference between the series of these characteristics for the premonsoon period and the period of the steady enthalpy decrease and heat and moisture flux increase is significant. Monsoon onset can be predicted from the moment

when H and Ep stop oscillating drastically and H starts decreasing steadily Author (ESA)

Of the Nearly 1000 standard infrared photographic images received, 273 images were on computer compatible tape. It proved necessary to digitally enhance the scene contrast to cover only a select few degrees K over the photographic grey scale appropriate to the scene-specific range of sea surface temperature (SST). Some 178 images were so enhanced. Comparison with sea truth show that SST, as seen by satellite, provides a good guide to the ocean currents and eddies off East Australia, both in summer and winter. This is in contrast, particularly in summer, to SST mapped by surface survey, which usually lacks the necessary spatial resolution.

F. J. WENTZ 4 Nov. 1981 58 p refs

(Contract JPL-954958)

(NASA-CR-169083, JPL-9950-652; NAS 1 26.169083,

RSS-TR-110481) Avail: NTIS HC A04/MF A01 CSCL 20N

A relatively simple model for the microwave brightness temperature of sea surface Sun glitter is presented. The model is an accurate closeform approximation for the fourfold Sun glitter integral. The model computations indicate that Sun glitter contamination of on orbit radiometer measurements is appreciable over a large swath area. For winds near 20 m/s, Sun glitter affects the retrieval of environmental parameters for Sun angles as large as 20 to 25 deg. The model predicted biases in retrieved wind speed and sea surface temperature due to neglecting Sun glitter are consistent with those experimentally observed in SEASAT SMMR retrievals. A least squares retrieval algorithm that uses a combined sea and Sun model function shows the potential of retrieving accurate environmental parameters in the presence of

LANDSAT multispectral scanner data of the smoke plumes which originated in eastern Cabo Frio, Brazil and crossed over into the Atlantic Ocean, are analyzed to illustrate how high resolution LANDSAT imagery can aid meteorologists in evaluating specific air pollution events. The eleven LANDSAT images selected are for different months and years. The results show that diffusion is governed primarily by water and air temperature differences. With colder water, low level air is very stable and the vertical diffusion is minimal; but water warmer than the air induces vigorous diffusion The applicability of three empirical methods for determining the horizontal eddy diffusivity coefficient in the Gaussian plume formula was evaluated with the estimated standard deviation of the crosswind distribution of material in the plume from the LANDSAT imagery. The vertical diffusion coefficient in stable conditions is estimated using Weinstock's formulation These results form a data base for use in the development and validation of meso scale atmospheric diffusion models. ICE DISTRIBUTION AND WINTER SURFACE CIRCULATION PATTERNS, KACHEMAK BAY, ALASKA

L. W. GATTO Dec 1981 52 p refs

(AD-A110806; CRREL-81-22) Avail: NTIS HC A04/MF A01 CSCL 08C

Development of the hydropower potential of Bradley Lake, Alaska, would nearly double winter freshwater discharge from the Bradley River into upper Kachemak Bay, and the Corps of Engineers is concerned about possible subsequent increased ice formation and related ice-induced problems. The objectives of this investigation were to describe winter surface circulation in the bay and document ice distribution patterns for predicting where additional ice might be transported if it forms Fifty-one LANDSAT MSS band 5 and 7 and RBV images with 70% cloud cover or less, taken between 1 November and 30 April each year, were analyzed for the eight winters from 1972 to 1980 with standard photointerpretation techniques Results of this analysis showed that glacial sediment discharged into Kachemak Bay acts as a natural tracer in the water Inner Kachemak Bay circulation in the winter is predominantly counterclockwise, with northeasterly nearshore currents along the south shore and southwesterly nearshore currents along the north shore. Most of the ice in the inner bay forms at its northeast end and is discharged by the Fox, Sheep and Bradley Rivers. Some ice becomes shorefast on the tidal flats at the head of the bay, while some moves southwestward along the north shore pushed by winds and currents. When this ice reaches Coal Bay, it accumulates between Homer Spit and the north shore. This buildup extended out to Coal Point at the tip of Homer Spit in February 1976 and 1979; ice was not observed in the nearshore zone along the south shore of the inner bay. GRA

SATELLITE OBSERVATIONS IN FRONTS 80

M. L. VANWOERT Nov 1981 44 p refs

(Contract N00014-80-C-0440)

(AD-A111080; SIO-REF-81-38) Avail: NTIS HC A03/MF A01 CSCL 08J

Early observations in the Central North Pacific indicate a general decrease in temperature and salinity as one moves northward from the equator. The change is not a smooth function of latitude, but rather, superimposed on a steady poleward decrease of temperature and salinity are regions of abrupt change called fronts (Seckel, 1968; Roden 1972). The general strength and location of the mid-ocean fronts are well-known. Near 45 deg. N latitude is the Pacific Subarctic Front. It separates the Pacific Subarctic water mass from the North Pacific Central water mass and is characterized by a change of 4 C per 30km and 0 6% per 30km across the front. In the vicinity of 32 deg. N is the Pacific Subtropical Front, It separates the North Pacific Central water mass from the Pacific Equatorial water mass and is characterized by a change of 2 deg. C per 30km and 0 25% per 30km across the front (Roden, 1975). A schematic map of the Central North Pacific Fronts is shown. Although the general location and strength of the mid-ocean fronts are well documented, little is known about variability associated with frontal strength and position. In December 1979 a large observational program (FRONTS 80) was undertaken to obtain basic scale information on a mid-ocean front. The North Pacific Subtropical Front, near 31 deg. N, 153 deg. W was chosen as the experiment site because of its logistical proximity to the U.S. mainland and Hawaii, and because extensive historical data exists for this region. GRA

RAPID OCEANOGRAPHIC DATA GATHERING: SOME PROBLEMS IN USING REMOTE SENSING TO DETERMINE THE HORIZONTAL AND VERTICAL THERMAL DISTRIBUTIONS IN THE NORTHEAST PACIFIC OCEAN M.S. Thesis G. W. LUNDELL Sep 1981 189 p refs

(AD-A111005; NPS68-81-006) Avail: NTIS HC A09/MF A01 CSCL 08J

NOAA-6 satellite AVHRR data and AXBT data were collected in the Northeast Pacific Ocean in late 1980 as part of the Naval Postgraduate School-sponsored Acoustic Storm Transfer and Response Experiment which was in turn part of the U.S -Canadian Storm Transfer and Response Experiment (STREX) Some of the problems in transferring AXBT geographical positions to satellite images were solved by designing a computer program with accuracies of less than 2 pixels Thermal comparisons were made between AXBT, NOAA-6, and GOSSTCOMP data with the result that NOAA-6 data was on the average of 2.9 C colder than AXBT data and 3.2 C colder than GOSSTCOMP data. Linear regression methods reduced to 0.3 C the difference between NOAA-6 and AXBT data. Use of this method over a period of 15 days produced a mean error of 0.5 C. Although NOAA-6 cannot sense directly the subsurface thermal structure, it is excellent for observing surface manifestations of horizontal thermal features. Further investigation into using satellite data as the basis of an empirical relationship between the surface temperature and the subsurface vertical thermal structure is warranted. Author (GRA)

(AD-A110838, SIO-REF-81-27) Avail. NTIS HC A05/MF A01 CSCL 08C

This research seeks to predict shelf and beach forms and their changes from knowledge of local bathymetry and the driving forces due to winds, waves and currents and their complicated interactions with nearshore sediments. The work falls into three distinct but interdependent areas of research wave and current dynamics; fluid-sediment interactions; coastal zone remote sensing. The principal area of interest in wave and current dynamics continues to be wind generated, surface gravity waves and the currents and other fluid motions which derive their energy from surface waves. The fluid sediment interaction studies lead to an understanding of the shelf and beach sediment response including the fundamental rheology of granular fluids, the longshore and on-offshore transport of sand and the formation of features like cusps and bars The coastal zone remote sensing tasks are largely exploratory in nature, with the general objective of determining the extent to which signatures from remote sensors can be used to define the broader spatial characteristics of driving forces, and the larger scale ocean surface patterns that are characteristic of nearshore dynamics Author (GRA)

MOVEMENT OF ICE MARKERS MEASURED BY SATELLITE RANGING

P. GUDMANDSEN, C. CARLE, and J. MAALOEE ' Paris ESA Jun. 1981 82 p refs

(Contract ESA-4634/81)

(R-240, ESA-CR(P)-1547) Avail: NTIS HC A05/MF A01

A method for determining the surface velocity of large ice sheets in Greenland and Antarctica involves measuring the change of distance between fixed markers and those on ice sheets, using ERS-1 for altimetry and radar ranging. An acceptable signal to noise ratio can be obtained with the ERS-1 high gain antenna and a marker, consisting of a square trihedral corner reflector, with side length = 1.5 m, radar cross section 55 dB. The high gain antenna limits the area investigated to an 18 km swath, assuming a 5 deg incidence angle. A Swerling type radar cross section of the corner reflector results in a 62% detection probability for 6-pulse integration. Displacement of markers can only be measured at crossing ground tracks when the satellite is operated in a rigid orbit mode, i.e., a 20 X 20 km area. Accuracy of 78 cm is possible Author (ESA) N82-27949# National Weather Service, Fort Worth, Tex. National Hurricane Center.

SOME EMPIRICAL RULES FOR FORECASTING FOG AND STATUS OVER NORTHERN FLORIDA, SOUTHERN GEORGIA AND ADJACENT COASTAL WATERS

E. L. RICKS Aug. 1981 15 p refs

(PB82-154006; NOAA-TM-NWS-SR-104, NOAA-81111608) Avail. NTIS HC A02/MF A01 CSCL 04B

Strong low-level winds, especially strong vertical wind shear, generate and maintain enough mixing helow the subsidence inversion over southern Georgia and northern Florida to counteract, or inhibit, low stratus and fog formation. Weaker northeast and east winds flavor low stratus and fog formation over southern Georgia and northern Florida when the trajectory is from the Atlantic coast GRA

EFFECTIVE ELECTROMAGNETIC SHIELDING IN MULTILAYER **PRINTED CIRCUIT BOARDS**

K. G. WILES and J. L. MOE (General Dynamics Corp., Fort Worth, TX) In Digital Avionics Systems Conference, 4th, St. Louis, MO, November 17-19, 1981, Collection of Technical Papers. New York, American Institute of Aeronautics and Astronautics, 1981, p 593-596

(AIAA 81-2333)

Multilayer printed circuit boards have proven to be recurrent abettors of electromagnetic coupling problems created by the incessantly faster response times in integrated circuit technologies Coupling within multilayer boards has not only inhibited meeting certain EMI requirements but has also precipitated 'self-inflicted' malfunctions commonly experienced during development of avionic systems. A recent avionic system, interfacing two asynchronous processors through a fourteen-layer motherboard, permitted coupling through ground plane connector apertures of sufficient amplitude and duration as to cause unintentional intercommunication and system malfunctions. The coupling mechanism and ground plane modifications which reduced this coupling by 40 dB and eliminated the incompatibility are discussed in this paper (Author)

THE MODULATION CHARACTERISTICS OF THE 19TH AND 20TH SOLAR ACTIVITY CYCLES

N N KONTOR, G. P. LIUBIMOV, N. V. PERESLEGINA, and T. I. STEPINA (Moskovskii Gosudarstvennyi Universitet, Moscow, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 179-182 refs

The intensity modulation of galactic cosmic rays at 1 AU from the sun is described in terms of the nonstationary model. The dependencies of the modulation coefficients are found, which characterize the galactic cosmic ray fluxes to and from the sun on the solar activity level, and consideration is given to the dependencies of the modulation parameters on time and cosmic ray energy. Significant variations are observed in the modulation factors, even for the smoothed data, and the transparency coefficient is proportional to the particle energy, while the transfer coefficient is inverse D.LG.

A SIMULATION STUDY OF SOIL MOISTURE ESTIMATION BY A SPACE SAR

F. T ULABY, C. DOBSON, J. STILES, R. K. MOORE, and J. HOLTZMAN (University of Kansas Center for Research, Inc, Lawrence, KS) Photogrammetric Engineering and Remote Sensing, vol 48, Apr 1982, p. 645-660. refs

An evaluation of the accuracy of soil moisture estimates available from satellite radar remote sensing is made, along with an assessment of the effects of spatial resolution on the estimation accuracy Synthetic aperture radar (SAR) images of a 17.7 x 193 km test site were generated by image simulation techniques for a space SAR orbiting at 600 km and operating at 4 75 GHz, an HH polarization, and an angle of incidence range between 7-22 deg from nadir Data bases were constructed of U-2 color IR photographs, 20 m x 20 m pixel soil elements from the USDA totalling 800,000 pixels classified for target class, soil texture, and surface elevation Three sets of images were generated for four varying soil moisture distributions across the site Soil moisture in 90% of the 20 m x 20 m pixels were found to be predictable in terms of moisture capacity to within 20%. A 100 m x 100 m resolution was best for very dry soil conditions M.SK

INTERPRETATION OF SURFACE-WATER CIRCULATION, ARANSAS PASS, TEXAS, USING LANDSAT IMAGERY

R. J. FINLEY and R. W BAUMGARDNER, JR (Texas, University, Austin, TX) Remote Sensing of Environment, vol. 10, Aug. 1980, p.3-22. refs

(Contract NAS5-20986)

The development of plumes of turbid surface water in the vicinity of Aransas Pass, Texas has been analyzed using Landsat imagery The shape and extent of plumes present in the Gulf of Mexico is dependent on the wind regime and astronomical tide prior to and at the time of satellite overpass. The best developed plumes are evident when brisk northerly winds resuspend bay-bottom muds and flow through Aransas Pass is increased by wind stress. Seaward diversion of nearshore waters by the inlet jetties was also observed. A knowledge of surface-water circulation through Aransas Pass under various wind conditions is potentially valuable for monitoring suspended and surface pollutants (Author)

THE GROWTH OF SNOW IN WINTER STORMS - AN AIRBORNE OBSERVATIONAL STUDY

K K. LO and R. E. PASSARELLI, JR (MIT, Cambridge, MA) Journal of the Atmospheric Sciences, vol. 39, Apr. 1982, p. 697-706. refs

(Contract F19628-80-C-0021)

In studies of precipitation growth, comparisons between theory and observation are difficult because of the problem in obtaining a complete four-dimensional (space and time) description of the kinematic, thermodynamic and microphysical properties of the atmosphere. A new flight plan has been devised which permits one to observe the height evolution of snow-size spectra in a reference frame where the effects of horizontal gradients and temporal changes are minimized. The flight plan, termed the advecting spiral descent (ASD), requires an aircraft to start aloft in a mesoscale precipitation area and then spiral downward in a constant bank angle, descending at approximately the mean fallspeed of snow. Qualitative comparisons between ASD observations and particle growth theory suggest that snow evolves through at least three stages characterized by deposition, aggregation and breakup. The breakup process serves to limit the number of large snow particles and interacts with aggregation to produce a limiting value of the slope of the snow-size spectrum (Author)

AUTOMATED CLASSIFICATION OF RUNOFF COEFFICIENTS FROM LANDSAT MULTISPECTRAL DATA

F ASKARI (Ohio State University, Columbus, OH) and N. L. FAUST (Georgia Institute of Technology, Atlanta, GA) In: American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p. 426-439. Research supported by the Ohio State University Research Foundation refs

Multispectral data from Landsat are used with aircraft color infrared photography to derive the runoff coefficients for watersheds in Mill Creek, Ohio Regression models are developed from the treatment of the runoff coefficient of each sample site as the dependent variable, and the mean radiance measurements in the four Landsat channels as the independent variables. A comparison of classification results illustrates the spatial and temporal variations of runoff potential for the surface. Single cover test fields and test watersheds are used to verify the model results, and the mean runoff coefficients derived for the test watersheds from the multispectral data analysis technique compare favorably with those obtained from ground truth DLG.

USE OF AERIAL PHOTOGRAPHY IN DETERMINING LAND USE AND STREAMFLOW RELATIONSHIPS ON SMALL DEVELOPING WATERSHEDS

M. OWE (NASA, Goddard Space Flight Center, Hydrological Sciences Branch, Greenbelt, MD) In American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p 466-475. refs

Using aerial photographs dating back to 1937, the historical trends of five land use classes (crop, forest, open field, urban and suburban) are determined. The relationships between these and various flow regime parameters are investigated. Annual runoff is found to be 75 inches greater now than in the year 1932. It is also found that growing season runoff increased by 3.5 inches during the same period This increase is approximately equivalent to 160 area inches of excess runoff during the 45-year period of observation. The increase in runoff is found to be positively correlated with the percent basin area in the urban, suburban and open field land use classes. A negative correlation is established with forest and crop land Although poor correlations are found with high flow, low flow, flow interval and flow date data, it is thought that a more precise quantification of land use or a smaller basin area may possibly have yielded more positive results for streamflow timing data. C.R.

A82-34745

AERIAL PHOTOGRAPHY VS. LANDSAT FOR DIGITAL LAND-COVER MAPPING IN AN URBAN WATERSHED

B. K. QUIRK and F. L. SCARPACE (Wisconsin, University, Madison, Wi) In American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p 610-617. refs

A comparison was made between digital analyses of color infrared film and Landsat to provide land-cover information in an urban watershed. The results were compared to a manual photo interpretation of a black and white infrared photograph. Both the color infrared and Landsat produced similar land-cover acreages and both were similar to the black and white interpretation. However, the color infrared was found to be a better representation. (Author)

REMOTE SENSING IN SCOTLAND USING DATA RECEIVED FROM SATELLITES - A STUDY OF THE TAY ESTUARY REGION USING LANDSAT MULTISPECTRAL SCANNING IMAGERY

A P CRACKNELL, N. MACFARLANE, K MCMILLAN, J. A. CHARLTON, J. MCMANUS (Dundee, University, Dundee, Scotland), and K. A ULBRICHT (Deutsche Forschungsund Versuchsanstalt fuer Luft- und Raumfahrt, Oberpfaffenhofen, West Germany) International Journal of Remote Sensing, vol 3, Apr.-June 1982, p. 113-137 Research supported by the Carnegie Trust and Science and Engineering Research Council. refs

Multispectral scanning data from Landsat are used to study the sandbanks and tidal flats in the Tay Estuary, and the specialized digital image-processing system used in the study is briefly described. Several examples of Landsat-2 images of the Tay Estuary and its environs are presented as false-color composites and monochrome pictures, and a qualitative interpretation and several quantitative ones are presented. The low-water mark for sandbanks in the upper and lower estuary is determined and the results are compared with existing charts and maps, showing that changes in the positions of sandbanks of the size found in the estuary can be monitored satisfactorily using satellite imagery. The position of an estuarine front is mapped and also observed in situ in the position indicated by this image. An attempt at quantitative bathymetry, using a high tide Landsat image, indicated that depths up to three or four meters can be determined from the satellite data, but the accuracy is rather poor. BIAS CORRECTION PROCEDURES FOR AIRBORNE LASER **HYDROGRAPHY**

G. C. GUENTHER and R. W. L. THOMAS Aug. 1981 110 p refs Prepared in cooperation with EG and G Washington Analytical Services Center, Inc., Rockville, Md. sponsored in part by Naval Ocean Research and Development Activity, NSTL Station, Miss. (PB82-130089; NOAA-TR-OTES-03; NOAA-8110502) Avail. NTIS HC A06/MF A01 CSCL 08J

Depending on the entry nadir angle of the beam and the optical properties of the water, one of two opposing effects, multiple scattering and geometric 'undercutting', will dominate and result in either a deep or shallow depth measurement bias, respectively. The magnitude of this bias can greatly exceed international hydrographic accuracy standards, and hence bias correctors must be calculated and applied to the raw depths in postflight data processing to attain the required accuracy for the overall system. The magnitudes of the bias correctors depend not only on the water and flight parameters, but also on the basic design of the receiver electronics. Several typical systems and procedures required to calculate a set of bias correctors for any given system are described and a cookbook approach for the necessary postflight data processing algorithms are included. A STATISTICAL APPROACH TO RAINFALL ESTIMATION USING SATELLITE AND CONVENTIONAL DATA

L. F WHITNEY, JR. Apr 1982 55 p refs (NOAA-TR-NESS-89) Avail NTIS HC A04/MF A01

A statistical approach is employed in an attempt to estimate convective rainfall using both satellite and conventional data. A variety of variables derived from both satellite and conventional meteorological sources are presented. From among these variables, a screening regression method selects those which best explain area-averaged rainfall. Among the cases studied, the relationship of each variable to rainfall is weak to poor, particularly as cases are combined. Although multivariate selections improve the relationships, inconsistency of selection develops from one case to another and from one time to another, even in the same meteorological situation Regression equations are found to estimate the amount inadequately, even when using dependent data At best, rainfall is not likely to be measured quantitively by such an approach and, at worst, concern is raised about the validity of using the variables investigated to estimate rainfall.

INPE-2249-TDL/066) Avail: NTIS HC A12/MF A01 CSCL 05B The relationship between the dispersion and concentration of sediment in the superficial layers of the Tres Marias reservoir and the dynamics of the drainage basins of its tributaries was verified using LANDSAT MSS imagery. The drainage network, dissection patterns, and land use of each watershed were considered in an analysis of multispectral images, corresponding to bands 4,5, and 7, of dry and rainy seasons in 1973, 1975, 1977, and 1978. The superficial layer water layers of the reservoir were also divided according to the grey level pattern of each image. Two field trips were made to collect Secchi depths and in situ water reflectance. It is concluded that it is possible to determine the main factors that act in the dynamics of the drainage basins of a reservoir by simultaneous control of the physical variables and the antropic action of each basin. HCMM HYDROLOGICAL ANALYSIS IN UTAH Quarterly Progress Report

28 Feb. 1982 43 p Sponsored by NASA HCMM

(E82-10328, NASA-CR-168907, NAS 1.26-168907; QPR-3) Avail: NTIS HC A03/MF A01 CSCL 05B

Temperature calibration and groundwater depth location studies were finalized. Distinctions among algae species and among suspended materials (turbidity) using HCMM data were investigated. Field evaluations of algae's effect on evaporation pan readings were completed and related to the lake and HCMM data. Additional correlations among infrared and reflectivity data were made using the color graphics capabilities developed during this project

FRAGMENTATION OF FE NUCLEI ON CARBON, HYDROGEN AND CH2 TARGETS. I - INDIVIDUAL CHARGE CHANGING AND TOTAL CROSS SECTIONS. II - ISOTOPIC CROSS SECTIONS

D. A BRAUTIGAM, J. H CHAPELL, J. C. KISH, G. A. SIMPSON, and W R. WEBBER (New Hampshire, University, Durham, NH) In International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 173-180. refs

(Contract NGR-30-002-052)

The fragmentation of Fe nuclei in carbon and CH2 targets at energies of 650, 800, and 950 MeV/nuc has been studied. Direct measurements of the interaction between Fe nuclei and the carbon and CH2 targets were carried out. The Fe to H charge changing cross sections derived for selected nuclei showed a clear energy dependence, consistent with the results of Westfall et al. (1979) Values for the total inelastic cross section Fe to H charge changing were obtained by two methods: the first method involved subtracting the total CH2 and C cross sections (values of 703 plus or minus 9 mb and 65 plus or minus 10 mb at 950 MeV/nuc and 650 MeV/nuc, respectively were obtained). The same cross sections were obtained by adding the individual charge changing cross sections A cross section for Fe to fragment into lower mass Fe isotopes of 65 plus or minus 5 mb was also observed, giving total inelastic mass changing cross sections of 768 plus or minus 11 mb and 716 plus or minus 12 mb, respectively. In addition, the individual isotopic cross sections for Z equals 16-25 are reported. JF.

ON THE CHARACTERISTICS OF THE VERY LOW ENERGY GALACTIC COSMIC RAYS IN THE INTERSTELLAR SPACE

M. B. KRAINEV (Akademila Nauk SSSR, Fizicheskii Institut, Moscow, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 186-189 refs

The interstellar spectra of several cosmic ray nuclei and ions (H, He, C, O) are calculated in the energy range T less than 1 MeV/n, where the charge-exchange processes become significant. The ionization energy loss and the processes of electron loss and capture are taken into account. The cosmic ray intensity calculation is discussed in detail, and spectra results are presented and interpreted J.F.

A82-22555* New Hampshire Univ., Durham THE CHARGE AND ISOTOPIC COMPOSITION OF Z EQUALS 7-16 COSMIC RAY NUCLEI AT THEIR SOURCE

W. R WEBBER (New Hampshire, University, Durham, NH) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 261-264 refs

(Contract NGR-30-002-052)

Using the combined data from our 1976 and 1977 balloon flights, the charge and isotopic composition of Z equals 7-16 cosmic ray nuclei have been determined A low abundance of both N and Ne in the cosmic ray source relative to solar cosmic rays is observed. However, the cosmic ray source ratio, Ne-22/Ne is 2.75 plus or minus 0.42 times the solar ratio. A possible enhancement of the Mg-26/Mg ratio, which is 1.29 plus or minus 0.14 times the solar ratio is also observed. (Author)

COSMIC RAY COMPOSITION FROM ACCELERATION OF THERMAL MATTER

J. PEREZ-PERAZA (Universidad Nacional Autonoma de Mexico, Villa Obregon, Mexico) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 273-276.

The source composition of cosmic rays is thought to be controlled by Coulombian interactions during the acceleration of thermal matter A given element is representative of the source or depletion depending on whether the predominant ionic state at the temperature of the source is lower than a threshold imposed by Coulombian losses Coupling this restriction to the theory of ionization equilibrium, the source abundances are calculated. The results corroborate sources of relatively low temperature. C.R.

A82-22568

ACCELERATION OF COSMIC RAYS IN ACCRETION SHOCKS

R COWSIK (Tata Institute of Fundamental Research, Bombay, India) and M A LEE (New Hampshire, University, Durham, NH) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 318-321. refs

Spherically symmetric accretion around condensed astronomical objects like white dwarfs, neutron stars and black holes very often go through a quasi-stationary shock close to the object. The transport of radiation, energetic particles and neutrinos in such flows is studied, and it is found that these are accelerated to high energies very efficiently. The generated spectra are seen to have power-law behavior when the diffusion coefficient is independent of particle momentum. The possibility that the bulk of the galactic cosmic rays are accelerated by approximately 10,000 neutron stars which are surrounded by dense interstellar clouds is briefly discussed. (Author)

A82-22573

THE GALACTIC ORIGIN OF COSMIC RAYS. II

S. A. COLGATE (Los Alamos National Laboratory, Los Alamos; New Mexico Institute of Mining and Technology, Socorro, NM) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 352-355. refs

(CONF-810711-2; LA-UR-81-966)

The cosmic ray pressure limit to cosmic ray acceleration in the interstellar medium (ISM) is considered it is found that the beta equals 1 Alfven speed streaming limit imposes a new and strong constraint on supernova-ISM shock models of cosmic-ray acceleration. A more detailed analysis is, therefore, required. Ultra-high energy cosmic rays are also discussed, giving attention to sources of cosmic rays inside and outside the Galaxy. In connection with complexities and constraints, one source for all energies within all galaxies is finally considered, taking into account a flattening of the source in slope and the characteristics of spectrum and flux produced by the shock ejection of the envelope of a type I supernova. G.R.

A82-22575

ASTROPHYSICAL SCENARIOS FOR CRITICALLY EVALUATING A ZERO-POINT FIELD ACCELERATION MECHANISM

A. RUEDA (Universidad de los Andes, Bogota, Colombia) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 361-364. refs

If the electromagnetic zero-point field of ordinary quantum theory is considered as a real field that may act on particles in the usual way that random fields act in classical electrodynamics, it is possible to show that electromagnetically interacting particles perform a random walk in velocity space to ever-increasing translational kinetic energies. As the zero-point field has a Lorentz invariant energy density spectrum, it can be shown that, in a very high vacuum an unconfined gas of infinitely many of those particle displays an energy spectrum of the form E to the (-eta) (eta is a parameter) when in equilibrium with the zero-point field Scenarios are presented in order to critically discuss and evaluate the possible astrophysical relevance of the model as applied to the acceleration of particles in intergalactic space (Author)

A82-22576

CALCULATION OF PRODUCTION RATES OF COSMOGENIC NUCLIDES BY MONTE CARLO METHOD

S TOKAR and P. POVINEC (Komenskeho Univerzita, Bratislava, Czechoslovakia) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 374-377 refs

A method is presented for the calculation of production rates of cosmogenic nuclides based on Monte Carlo simulations of hadronic cascade processes in matter Calculations are carried out for the case of a semi-infinite iron slab with a thickness of 2.5 m, and the hadronic cascade is assumed to consist only of nucleons and pions. The nuclide production is found to exhibit only a weak energy dependence, especially at higher energies. DLG.

A82-22577

MEASUREMENT OF COSMOGENIC NUCLIDES USING A MULTI-CRYSTAL GAMMA-RAY COINCIDENCE SPECTROMETER

J. C BARTON (North London, Polytechnic, London, England) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 378-381.

The activities of Na-22 and Al-26 in a recently fallen meteorite, Mayo Belwa, have been measured using an improved gamma-ray spectrometer. This uses six sodium iodide detectors, arranged symmetrically, so that extended samples can be measured. By recording total rates, 2-fold and 3-fold coincidences simultaneously, it is possible to correct for source absorption and other instrumental effects The absolute intensity of Al-26 was found to be comparable to that found in other meteorites, but that of Na-22 is anomalously high (Author)

A82-22578

NUCLEOSYNTHESIS OF LIGHT AND BY-PASSED ISOTOPES IN THE SOLAR SYSTEM MATTER

A. K. LAVRUKHINA and R. I. KUZNETSOVA (Akademila Nauk SSSR, Institut Geokhimil I Analiticheskoi Khimil, Moscow, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 382-385. refs

A model of nucleosynthesis of light and by-passed isotopes is proposed, which is based on the idea that a supernova event led simultaneously to nuclei explosion burning, to collective acceleration of particles up to relativistic energies by shock waves, and to spallation reactions. It is shown that solar system matter was formed in two main events of intensive nucleosynthesis. The first event led to the formation of about 99 percent of K-40, V-50, and the by-passed isotopes with A not less than 113. The second event led to the formation of observed abundances of isotopes and about 1 percent of other products of spallation reactions. Proton fluxes, the alpha/p value, the gamma value, irradiation duration, and the sequence of nucleosynthesis processes are obtained. D.L.G.

INTERNATIONAL COSMIC RAY CONFERENCE, 17TH, PARIS, FRANCE, JULY 13-25, 1981, CONFERENCE PAPERS. VOLUME 3 [CONFERENCE INTERNATIONALE SUR LE RAYONNEMENT COSMIQUE, 17TH, PARIS, FRANCE, JULY 13-25, 1981, CONFERENCE PAPERS. VOLUME 3]

Conference sponsored by CEA, IUPAP, CESR, et al Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981. 543 p. In French and English.

The sun and heliosphere are examined from satellite data of solar cosmic ray events recorded by satellite and theories of the interplanetary propagation of particles and particle acceleration within the heliosphere Attention is given to X ray, radio, energetic electron, gamma ray, and nuclear reactions of energetic protons observations of solar activity. Ground-, balloon-, and satellite-based detection of particle events are discussed, along with data relevant to the propagation of particles, especially for He-3 enriched events. Modulation of galactic cosmic rays by the solar cycle is explored, and theories of the interplanetary propagation of particles within the heliosphere are investigated, including the effect of planetary magnetospheres on the solar-accelerated particles. MS K.

A82-22581

MODEL FOR SOLAR HARD X-RAY BURSTS

 M. YOSHIMORI (Rikkyo University, Tokyo, Japan) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 4-7. Balloon-borne observations of the hard X ray burst event of

Balloon-borne observations of the hard X ray burst event of Sept 19, 1979 are presented as a basis for a description of the temporal behavior of a number of electrons. One Nal(TI) monitor and four Nal(TI) counters provided measurements in the energy ranges 30-50, 50-80, 80-120, and 120-200 keV with a counting rate of 1 sec. The energy spectra of the hard X rays were correlated with solar flares and sunspots, and were fitted to power law forms evaluated at the sampling time. A trap-plus-precipitation model describes accelerated electrons as being magnetically trapped and precipitated onto a denser region, leading to hard X ray emission, yielding an electron/X ray ratio calculated to be 1,700,000, in accord with other observations. A thermal model approximated the energy spectrum of hard X-rays by the thermal radiation spectrum from hot plasma, with vanations in temperature and emission. M S.K.

THE DETERMINATION OF DIFFERENTIAL X-RAY SPECTRUM OF THE SOLAR FLARE USING IONOSPHERIC DATA

I D KOZIN (Akademia Nauk Kazakhskoi SSR, Sektor lonosfery, Alma-Ata, Kazakh SSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 8-10.

The ionization velocity of X rays from a solar flare entering the lower ionosphere is determined by first assuming that the X ray spectrum outside the atmosphere is described by a third degree polynomial. The absorption of monochromatic radiation is modeled as a function of atmospheric density, of the absorption cross-section, and of the path length. The ionosphere is divided into three levels, from which coefficients are calculated from data on ionization from the X ray flux Substitution of the coefficients into the third degree polynomial equation yields the differential X ray spectrum.

UNUSUAL PROPERTIES OF PARTICLE EVENTS ASSOCIATED WITH SOLAR FLARE GAMMA RAY EVENTS

P EVENSON, P. MEYER, and S. YANAGITA (Chicago, University, Chicago, IL) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 32-35. refs

(Contract NAS5-20674)

An attempt to establish a link between gamma rays observed at the earth with solar flare areas highly enriched with electrons is presented. Two hour averages of the counting rates of 5-100 MeV electrons and 25-145 MeV protons performed on the ISEE-3 spacecraft were correlated with solar flares with a maximum intensity of 6-11 MeV electrons and 25-44 MeV protons recorded by other observers. The coverage was part of the Solar Maximum Mission, which attained a 50 percent coverage. Gamma ray associated events showed high ratios of electrons to protons, about 0 2, and electrons with energies greater than 80 MeV were observed, which are values high enough to produce the highest gamma rays observed, 40 MeV. The available data for electron. proton, and rare isotope fluxes and the time histories of the fluxes are noted to provide a data base for further information on solar flares and particle acceleration mechanisms MSK.

OBSERVATIONS OF INTERPLANETARY ENERGETIC CHARGED PARTICLES FROM GAMMA-RAY LINE SOLAR FLARES

M. E PESSES, G GLOECKLER (Maryland, University, College Park, MD), B KLECKER, and D. HOVESTADT (Max-Planck-Institut fur extraterrestrische Physik, Garching, West Germany) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p 36-39. Bundesministerium fur Forschung und Technologie refs (Contract BMFT-RV14-B8/74,

BMFT-01-01-017-ZA/WF/WRK-1754; NAS5-20062)

Results from ISEE-3 experiments on interplanetary energetic charged particles on June 7, June 21, and July 1, 1980 dealing with gamma ray producing solar flares are reported. The data were gathered by the Ultra Low Energy Wide Angle Telescope, which comprises a thin window, flow through proportional counter/solid-state detector composition telescope. Evidence of a specified time delay from an observed flare and the recording of 0.44-1.3 MeV electrons on ISEE-3 combined with quiescent periods of at least two hours before the observations and recording provides a link between the events. The data indicates interplanetary energetic particle enhancement, and a second, similar set of occurrences was also observed Protons were accelerated up to 10-20 MeV. No enrichment of either He-3 or Fe was found. A82-22590

AZIMUTHAL PROPAGATION OF FLARE PARTICLES IN THE HELIOSPHERE

J PEREZ-PERAZA and J. MARTINELL (Universidad Nacional Autonoma de Mexico, Villa Obregon, Mexico) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 3 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 55-58. refs

Empirically determined properties of solar coronal particle transport are used to quantitatively describe coronal propagation. A velocity dependence of the transport is formulated based on the diffusive nature of the transport and the observation that a drift motion acts on the particles. Both characteristics are assumed to be applicable outside of the fast propagation region, where convective processes dominate. An evolution of particle density is defined, and time profiles of the distribution are calculated for the two regions just before propagation into outer space. A prediction of prompt particles is made, and is caused by contact between the expanding magnetic bottle and field lines of opposite polarity, which leads to a tearing mode instability and a transfer of energy excess to thermal particles. A calculation of the growth time of the instability shows that particles will be observed before the flare particles appear. MSK

SURFACE TEMPERATURE DETERMINATION FROM AN AMALGAMATION OF GOES AND TIROS-N RADIANCE MEASUREMENTS

J. A. ZANDLO, W. P. MENZEL (Wisconsin, University, Madison, WI), W. L. SMITH, and C. M. HAYDEN (Wisconsin, University; NOAA, National Earth Satellite Service, Madison, WI) Journal of Applied Meteorology, vol. 21, Jan 1982, p. 44-50.

A technique for exploiting the TIROS-N capability of measuring the earth skin surface temperature and the GOES ability to monitor surface changes with fine temporal and horizontal resolution is described. Atmospheric absorption due to water vapor is assumed to vary slowly in space and time relative to the same scales of the GOES observations, thus allowing a horizontally varying correction field derived from 6-hr TIROS-N data to be used to obtain quasi-continuous surface temperature features from the GOES data. Additionally, a field of temperature differences between the corrected TIROS-N window channel brightness temperatures and uncorrected GOES brightness temperatures are specified. The GOES temperatures are then correctable to within six hours Two examples are provided of regional temperature assessments with comparison with surface-measured data and accuracy with the satellite data is within 1 K. DEVELOPMENT OF THREE-DIMENSIONAL SPATIAL DISPLAYS USING A GEOGRAPHICALLY BASED INFORMATION SYSTEM B. G JUNKIN (NASA, National Space Technology Laboratories, Earth Resources Laboratory, Bay Saint Louis, MS) Photogrammetric Engineering and Remote Sensing, vol 48, Apr 1982, p. 577-586. refs

Procedures necessary for the development of a generalized three-dimensional perspective software capability in support of graphic, topographic, and color mapping of Landsat data are reviewed The NASA Earth Resources Laboratory developed the procedures in order to facilitate the processing and analysis of disparate, geographically oriented base maps from aircraft and satellite sensors Perspective displays are obtained through a translation of the space-viewed object to a vantage point coordinate system, followed by a rotation through two angles for alignment along the vantage line of sight, and finally a perspective transformation to yield two-dimensional displays with no hidden lines Matrix equations for the transformations are reviewed, including scaling, and block diagrams are provided of the data and perspective software systems The classification data plane may be mapped onto a topographic elevation data plane M.S.K.

A82-29328

THE USE OF RESIDUAL IMAGES IN LANDSAT IMAGE ANALYSIS

D. L. B JUPP and K. K MAYO (Commonwealth Scientific and Industrial Research Organization, Div. of Land Use Research, Canberra, Australia) Photogrammetric Engineering and Remote Sensing, vol 48, Apr. 1982, p. 595-604. refs

Methods of classification of Landsat data for interactive image display and analysis are reviewed, and the use of the residual image to improve the postclassification analysis is examined. The mean image is formed from an accumulation of the mean radiance values from four channels, while the residual image is generated in the form of pixels in terms of the difference between the class mean and the actual measured radiance. The residual image facilitates detection of departures from hierarchical classes and patterns. A reference model is developed to standardize residual images, and gains in texture analysis during visual analysis are noted with inclusion of the residual images Examples are provided of land cover mapping an area in southeast Australia, and spectral class mapping on the northeast coast, where differences between inland and coastal vegetation are made visible using residual MSK. imagery

EXTRACTION OF LINE SHAPED OBJECTS FROM AERIAL IMAGES USING A SPECIAL OPERATOR TO ANALYZE THE PROFILES OF FUNCTIONS

W.-D. GROCH (Karlsruhe, Universitaet, Karlsruhe, West Germany) Computer Graphics and Image Processing, vol. 18, Apr. 1982, p 347-358. Research supported by the Bundesministerium fuer Forschung und Technologie and U.S. Army refs

Line-shaped objects are extracted sequentially by object-guided and object-specific methods with the facility for interactive support. The line following starts at locations which reliably are part of line-shaped objects. Two different object-guided methods may be initialized at these starting points. The methods follow the object by applying special operators to extract line segments. The operator is described that analyzes the function profiles, the detection of starting points, the two methods for line following and the combination of all methods in a system for the extraction of line-shaped objects from discrete gray level pictures. Results of a test are shown. C.D.

DEPENDENT FEATURE TREES FOR DENSITY APPROXIMATION. I - OPTIMAL CONSTRUCTION AND CLASSIFICATION RESULTS

C. B. CHITTINENI (Conoco, Inc., Ponca City, OK) International Journal of Remote Sensing, vol. 3, Jan.-Mar. 1982, p 31-44. refs

This paper deals with the approximation of probability density functions with dependent feature trees. The optimal dependent feature trees are proposed to be constructed using criteria of mutual information and distance measures. Expressions are derived for the criteria when the distributions of the features are Gaussian Expressions are developed for the covariances between the features connected by a path in a dependent feature tree. The case when the nodes in a dependent feature tree represent a set of features is also considered. Furthermore, experimental results from the classification of remotely sensed multispectral scanner imagery data are presented. (Author)

EVALUATION OF TEMPORAL REGISTRATION OF LANDSAT SCENES

R. NELSON and G. GREBOWSKY (NASA, Goddard Space Flight Center, Greenbelt, MD) International Journal of Remote Sensing, vol. 3, Jan.-Mar. 1982, p. 45-50. refs

The registration of Landsat images is important for multitemporal classification and for detecting change. Landsat data are now rectified to a ground coordinate system during preprocessing, hence scenes obtained over the same area are registered. The machine responsible for preprocessing the Landsat multispectral scanner data is the master data processor (MDP). This paper describes the rectification approach taken by the MDP, reviews the accuracy standards of the resultant product, and provides an assessment

of the accuracy of the scene to scene registration of two Landsat images. (Author)

THE USE OF CONTEXTUAL INFORMATION TO DETECT CUMULUS CLOUDS AND CLOUD SHADOWS IN LANDSAT DATA

C M. GURNEY (Reading, University, Reading, England) International Journal of Remote Sensing, vol 3, Jan -Mar. 1982, p 51-62 Research supported by the Atomic Energy Research Establishment. refs

The use of contextual information to identify areas of cloud and cloud shadow in digital Landsat data is described. The distance from cloud to shadow is calculated from sun elevation and azimuth, cloud base height and image geometry. Pixels with a gray level above a given threshold are considered to be potential cloud. A 3 x 3 pixel window centered at the calculated shadow position is searched. Pixels in this window with gray levels below a second threshold are classed as cloud shadow. If no shadow pixels are found the potential cloud is rejected. Modifications to allow for overlapping cloud and shadow are included. The detection procedure was found to work well for bands 5, 6, or 7 of Landsat data. (Author)

THE ESTIMATION OF WAVE HEIGHT FROM DIGITALLY PROCESSED SAR IMAGERY

M. H. B. THOMAS (Atomic Energy Research Establishment, Materials Physics Div, Harwell, Oxon, England) International Journal of Remote Sensing, vol. 3, Jan -Mar 1982, p 63-68 Research supported by the Department of Industry. refs

A simple method has been developed for estimating wave height from synthetic aperture radar (SAR) imagery obtained by the Seasat satellite. The method is based on measuring the contrast of the image and the wavelength of the dominant wave. A calculation has been made for two orbits made by the satellite over the North Atlantic in 1978, using digitally processed data supplied by DFVLR in West Germany. Comparison with sea truth measurements shows agreement to within about 20 per cent. (Author)

DIGITALLY ENHANCED VISUAL DISPLAYS FACILITATE THE ANALYSIS OF LANDSAT IMAGERY

R N COLWELL (Earth Satellite Corp., Berkeley, CA) In Display technology II; Proceedings of the Meeting, Los Angeles, CA, February 10, 11, 1981. Bellingham, WA, SPIE - The International Society for Optical Engineering, 1981, p. 118-126.

There have been efforts during most of the past decade to increase the interpretability of Landsat multispectral scanner (MSS) imagery through the performance of various kinds of image enhancement. Attention is given to research recently conducted for the U.S. Forest Service (USFS) with the objective to develop improved 'multiresource inventory methods' entailing the direct visual analysis of Landsat MSS imagery. The establishment of the resource categories to be identified is discussed along with approaches for producing the digitally enhanced visual displays, the preparation of the image analysis keys, the selection of personnel to evaluate the imagery, and the administration of the image interpretability tests. Preliminary results clearly showed that the studied procedure of enhanced visual display (color composite image in opaque print form) was significantly more interpretable than the conventional Landsat color composite imagery. A82-32581* Lowell Observatory, Flagstaff, Anz SUBTLETIES IN THE FLAT-FIELDING OF CHARGE-COUPLED **DEVICE /CCD/ IMAGES**

W. A. BAUM, B. THOMSEN, and T. J. KREIDL (Lowell Observatory, Flagstaff, AZ) In: Solid state imagers for astronomy, Proceedings of the Meeting, Cambridge, MA, June 10, 11, 1981 Bellingham, WA, SPIE - The International Society for Optical Engineering, 1981, p. 24-27.

(Contract NAS5-25451; NAS5-25488)

Astronomical photometry with CCDs will often involve relatively low signal levels (less than 1000 charge carriers per pixel), at which nonlinear effects sometimes become significant These effects will probably play a role in the processing of Space Telescope data. The problem apparently arises because signal charges are not read out equally completely from all columns and all pixels it is shown that, although a first-order correction can be made by subtracting a low-level flat field from all frames before conventional processing, higher accuracy can be achieved by modeling the response with a nonlinear function B.J.

A82-32709

COMPUTATION WITH PHYSICAL VALUES FROM LANDSAT **DIGITAL DATA**

C. J. ROBINOVE (U.S Geological Survey, Reston, VA) Photogrammetric Engineering and Remote Sensing, vol 48, May 1982, p. 781-784.

Although the analysis of Landsat digital images by using the digital numbers for each pixel recorded on a computer-compatible magnetic tape may be adequate when only a single, internally-consistent image is used, incorrect results will be given by the procedure if more than one image is used for analysis, as in mosaics or temporal overlays. The digital numbers for each pixel should in such cases be converted to their dimensionless equivalents, such as (1) radiance, as measured at the satellite, in mW/sq cm per steradian (sr), or (2) reflectance, both of which vary depending on the calibration of satellite MSS, sun angle, atmospheric state, terrain slope and aspect, and surface cover. Equations are given for radiance and reflectance calculations for the cases of five radiometric conditions, neglecting atmospheric correction O.C.

A82-32900

GEOGRAPHIC LOCATION OF INDIVIDUAL PIXELS

D. C. MCCONAGHY (NOAA, National Marine Fisheries Service, La Jolla, CA) Remote Sensing of Environment, vol 10, Aug. 1980, p 81-84. refs

A major problem in processing thermal infrared digital data from very high resolution radiometers aboard NOAA Polar Orbiting Satellites is the geographic placement of digital data fields. Geographic placement is especially difficult over oceanic areas because of the lack of landmarks. Using a series of geometric constructions, an analytical approach can be developed for geographic location of individual data pixels The errors associated with this method are generally less than 0.1 deg latitude and longitude. THE USE OF PRIOR PROBABILITIES IN MAXIMUM LIKELIHOOD CLASSIFICATION OF REMOTELY SENSED DATA

A. H. STRAHLER (California, University, Santa Barbara, CA) Remote Sensing of Environment, vol. 10, Sept 1980, p 135-163 refs

(Contract NAS9-15509; NAS7-100, NSG-2377)

Possibilities for the improvement of classification accuracies by the use of prior information about the expected distribution of classes in the maximum likelihood classification of remote sensing data are examined The modification of the maximum likelihood decision rule to take into account one or several sets of probabilities for the occurrence of classes which probabilities are based on independent knowledge of the area surveyed is demonstrated. It is then shown that the use of prior probabilities is sufficiently versatile so as to allow the prior weighting of output classes based on their anticipated sizes as well as the merging of continuously varying measurements with discrete collateral information data sets and the construction of time-sequential classification systems in which an earlier classification modifies the outcome of a latter A.L.W one

TERRAIN ANALYSIS FROM LANDSAT USING A COLOR TV **ENHANCEMENT SYSTEM**

T. H. L. WILLIAMS (Kansas, University, Lawrence, KS) and J. M. GOODMAN (Oklahoma, University, Norman, OK) Remote Sensing of Environment, vol. 10, Nov 1980, p. 231-237.

Visual interpretation of Landsat false-color composite imagery was employed to map terrain types on the Navajo Indian Reservation in northeastern Arizona and northwestern New Mexico. Three main difficulties were encountered in the visual analysis: (1) determination of the exact boundary positions; (2) repeatability of the boundary decisions over an area; and (3) discrimination among subtle tone differences associated with certain terrain type groupings. A simple image enhancement technique, based on a color television system was developed to make the visual analysis more accurate A color TV camera was used to view the image and a color monitor used for the display Image enhancement was achieved by use of the chroma, hue, contrast, and brightness controls on the monitor. The use of a zoom lens on the camera allowed rapid scale change and facilitated study of small areas of the image By working directly from a color image, the technique obviated the need for separation positives with their attendant registration problems. SEPARATION OF DIFFUSE FROM SHARP-EDGED FEATURES IN DIGITAL IMAGERY

G. F. BYRNE, P. F. CRAPPER, B. G. WILLIAMS, and M. J. GOODSPEED (Commonwealth Scientific and Industrial Research Organization, Div. of Land Use Research, Canberra, Australia) Remote Sensing of Environment, vol. 12, May 1982, p. 181-186. refs

A new classification procedure that removes sharp-edge features from digital imagery and that more clearly reveals any patterns more diffuse in nature that may be present is proposed. The procedure relies on the hypothesis that the sharp edges separate areas of uniform but differing optical density. These differences are frequently sufficiently large to obscure other patterns that are more diffuse ('fuzzy') in nature The technique is illustrated by application to a Landsat scene where a suspected mosaic arising from soil variability is overlain by agricultural fields. C.R.

A82-34469

EVALUATION OF THE EFFECTIVENESS OF SYSTEMATIC IMAGE DISTORTION COMPENSATION [OTSENKA EFFEKTIVNOSTI KOMPENSATSII SISTEMATICHESKIKH ISKAZHENII IZOBRAZHENIIA]

N G. BARABANOVA, K. N GERTSENOVA, and S S. NEKHIN Geodezia I Kartografiia, Apr. 1982, p. 32-36. In Russian

The improvements in image accuracy afforded by two methods for the compensation of systematic distortions in aerial photographs are studied. The techniques of field calibration, which involves the correction of image coordinates by interpolation from the coordinates of selected calibration points, and polynomial correction using additional reference points, in which the distortion field is approximated by second- and third-degree polynomials, were applied to aerial photographs subject to four different types of distortions Examination of the errors in the determination of the coordinates of control points and the maximum errors of their mutual positioning indicates field calibration to be more effective for sign-changing point displacements, while polynomial approximation is more effective for regular displacements.

A PRACTICAL STUDY OF GROSS-ERROR DETECTION IN BUNDLE ADJUSTMENT

S. F. EL-HAKIM (National Research Council, Ottawa, Canada) In: American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p. 1-17. refs

A special bundle adjustment program has been developed with built-in automatic gross-error detector by the data snooping approach. The program computes, in an efficient way, the exact values of the redundancy numbers for each image point. Using actual data, many of the factors affecting the reliability of bundle adjustment and the ability of the technique to detect gross errors are studied. The effects of different block parameters, point type and location, and the use of additional constraints are presented. (Author)

A82-34717

AN INFORMATION-THEORIC SPATIAL TRANSFORM

J. S. POWERS (Mississippi State University, Mississippi State, MS) In. American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers Falls Church, VA, American Society of Photogrammetry, 1981, p. 221-225. refs

Significant improvements in the sensitivity of existing computer algorithms for digital remote-sensor image classification may be effected without involving any software modification of these systems. An information-theoric spatial transform may be applied to the raw multispectral data set, and synthetic channels thus created may be utilized in the classification process. The transform is analogous in operation to the transform which occurs in the retina of higher organisms, a processing stage which has been omitted in most existing classification schemes. The transform algorithm is described and preliminary results of the application of the algorithm to the study of forest ecosystems from Landsat MSS image data are discussed (Author)

BATHYMETRIC IMAGING

P. R PALUZZI (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA) and M. C MALIN (Arizona State University, Tempe, AZ) In American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p. 247-258. refs (Contract NAS7-100)

Digital topography has, for some years, been formatted and processed into shaded relief images for specific studies involving land use and thermal properties Application to bathymetry is a new and seemingly fruitful extension of these techniques. Digital terrain models of the earth - combining subaerial topography with an extensive collection of bathymetric soundings - have been processed to yield shaded relief images. These images provide new and exciting insights into submarine geomorphology and portray many aspects of plate tectonic physiography in a manner not previously possible (Author)

A82-34722

A QUANTITATIVE METHOD TO TEST FOR SIMILARITY BETWEEN PHOTO INTERPRETERS

R. G CONGALTON and R. A. MEAD (Virginia Polytechnic Institute and State University, Blacksburg, VA) In. American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers Falls Church, VA, American Society of Photogrammetry, 1981, p. 263-266.

Photo interpretation is the art and science of identifying objects and deducing their significance on aerial photos. The judgment involved is generally qualitative in nature, and, therefore, difficult to evaluate or compare with interpretations made by others. The present investigation is concerned with an approach which makes it possible to quantify photo interpretation results, taking into account a statistical method for comparing these results. The proposed procedure can be employed in tests regarding the degree of similarity between interpreters or the consistency of the same interpreter over time. The procedure is based on the employment of an error matrix and the conduction of a discrete multivariate analysis to test the degree of similarity between the error matrices. G R

A82-34723

TERRAIN CLASSIFICATION BY FOURIER ANALYSIS -ACCURACY AND ECONOMY

P. FREDERIKSEN and O. JACOBI (Danmarks Tekniske Hojskole, Lyngby, Denmark) In: American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers Falls Church, VA, American Society of Photogrammetry, 1981, p. 267-284. refs

The Fourier transformation is applied to terrain profiles for classification purposes. Areas with different geology are considered, and the power spectra are estimated. The spectrum is used to predict the accuracy of a digital terrain model and to calculate some economic consequences of the relation between type of terrain, accuracy of measurements, point density, and surveying expenses. RAMS-1 is a Resource Analysis and Mapping System developed by Systemhouse. RAMS-1 will produce colour shaded thematic overlays as well as planimetric base maps This paper describes the hardware configuration and software facilities of the SHL RAMS-1 system (Author)

A82-34940

PRESENT STATUS OF ON-LINE ANALYTICAL TRIANGULATION

V. KRATKY (National Research Council, Ottawa, Canada) Photogrammetria, vol. 38, May 1982, p 1-12 refs

Basic principles of solutions suitable for analytical aerial triangulation are outlined and analyzed in the context of existing on-line photogrammetric systems. Two basic categories of procedures are considered: those which primarily aim for a quality controlled data acquisition followed by an off-line adjustment, and those which make the adjustment a part of the on-line procedure proper. The discussion covers geometrical as well as numerical considerations and emphasizes practical and methodological aspects which may bring about a higher efficiency of work and a reduction of preparatory operations. (Author)

INFLUENCE OF SKY RADIANCE DISTRIBUTION ON THE RATIO TECHNIQUE FOR ESTIMATING BIDIRECTIONAL REFLECTANCE

J. A. KIRCHNER (NASA, Goddard Space Flight Center, Earth Resources Branch, Greenbelt, MD), S YOUKHANA, and J A. SMITH (Colorado State University, Fort Collins, CO) Photogrammetric Engineering and Remote Sensing, vol 48, June 1982, p 955-959. refs

(Contract DACW39-77-C-0073, DARG29-79-C-0199)

The technique of ratioing scene radiance to the radiance obtained from standard Lambertian reference panels in order to estimate bidirectional reflectance factors may depend on the angular distribution of the diffuse irradiance field as well as the direct solar irradiance. A simulation study was performed to estimate the magnitude of this effect for differing clear sky irradiance distributions for a variety of vegetated surfaces. For the seven surfaces and wavelengths analyzed, the error induced in the estimation of bidirectional reflectance factors using the standard ratio technique was less than 5 percent for zenith view and sun angles less than 55 degrees (Author)

THE METEOROLOGICAL PRODUCT - 'CLOUD-TOP HEIGHT'

R. A. BOWEN (ESA, European Space Operations Centre, Darmstadt, West Germany) ESA Bulletin, no. 30, May 1982, p. 16-20.

The rationale for choices made in the method of presenting Meteosat IR and visual imagery to commercial users for visual analyses are examined. IR, at 11 microns, and water vapor (WV), at 6 microns, channels are noted to produce pictures in 2500 x 2500 pixel grids, while the 0.4-11 micron visible channel yields 5000 x 2500 pixel images. It was found necessary to digitally compress every picture by four in both directions for direct transmission to users. A resolution of 20 km was then available at the subsatellite point. Eight grey levels showed clouds above 12,000 m height in 1500 m steps to the 300 m level A correction for the semitransparency of clouds is numerically determined, particularly for overlying cirrus formations. User-activated corrections to images from remote terminals is described. A time lag of a little over two hours existed between Meteosat-1 acquisition and dissemination M.S.K.

SATELLITE RADIATION MEASUREMENTS FOR THE RETRIEVAL OF THE VERTICAL TEMPERATURE PROFILES [PRZETWARZANIE SATELITARNYCH POMIAROW PROMIENIOWANIA NA PIONOWE PROFILE TEMPERATUR]

Z. BUNSCH-MAKAREWICZ, B. BRAUN, and R. GOSS-ZUREK Acta Geophysica Polonica, vol 29, no. 3, 1981, p 235-246. In Polish refs

The physical basis underlying satellite IR determination of vertical temperature profiles in the atmosphere is detailed The earth is treated as a black-body emitting radiation at temperatures dependent only on the concentration, temperature, and absorption coefficient of the absorbents present in the atmosphere Consideration is given to regression analysis, the inverse matrix method, and direct retrieval techniques, noting that regression is preferred as the first choice in all cases and is the only method when transmission properties are not known. The level of agreement between derived profiles and measured values is shown to depend on the number of spectral frequency measurements. Good correlations are found, with the in situ data being slightly higher than the satellite figures. Examples are cited from TIROS N and NOAA spacecraft data M S.K.

LANDSAT D TO YIELD MORE PRECISE DATA

C. COVAULT Aviation Week and Space Technology, vol. 117, July 5, 1982, p. 40, 41, 46-48, 51.

The Landsat D spacecraft to be launched in mid 1982 will offer new multispectral and thermal imaging capabilities. The satellite is designed to improve the monitoring of renewable resources and to provide rock discrimination data for mineral and pertroleum geologists The expanded features of the new satellite include a seven-band thematic mapper with spectral ranges from 0.45-0.52 microns to 2.08-2.35 microns and a multispectral scanner capable of higher resolution and spectral fidelity than used in previous Landsats. The development of the Landsat D has been complicated by project changes both in the Space Shuttle and the Tracking and Data Relay Satellite Program, which resulted in an increase in weight (now 4400 lb.), an additional hydrazine tank and narrow band tape recorders. Other details on the spacecraft include total array output power of 2200 W, operational altitude of 705 km and launching on a Delta 3920 N.B.

ADVANCED TECHNOLOGY FOR EARTH OBSERVATION - DATA PROCESSING

P. HEFFNER and E CONNELL (NASA, Goddard Space Flight Center, Mission and Data Operations Directorate, Greenbelt, MD) American Astronautical Society and Deutsche Gesellschaft fuer Luft- und Raumfahrt, Goddard Memorial Symposium on Spacelab, Space Platforms and the Future, 20th, Greenbelt, MD, Mar. 17-19, 1982, AAS 18 p.

(AAS PAPER 82-130)

The Experimental Land Observing System (ELOS) is to demonstrate major advances in space-based land observation. Program success will depend upon successful demonstration of both space-segment performance and ground-system capabilities. Increases in data-rate, volume, and processing requirements present substantial challenges to the ground data processing system. ELOS is based on the utilization of the multispectral linear array (MLA) sensor, a solid-state, electronically scanned instrument. Current MLA instrument designs offer a number of capabilities beyond those provided in the Landsat imaging devices. These capabilities include greater resolution, inherent registration, onboard calibration, off-nadir pointing capability, and fore/aft pointing capability The proposed MLA flight mission scenario will be one of continued growth and will include flights on the Space Transportation System. Attention is also given to ground-to-ground data transport, data capture, and the use of high speed computers GR

SPHERICAL HARMONIC REPRESENTATION OF THE MAIN GEOMAGNETIC FIELD FOR WORLD CHARTING AND INVESTIGATIONS OF SOME FUNDAMENTAL PROBLEMS OF PHYSICS AND GEOPHYSICS Progress Report

D R. BARRACLOUGH, R. HIDE (Meteorological Office), B. R. LEATON, F J. LOWES (Newcastle-Upon-Tyne Univ.), S. R. C MALIN, and R. L. WILSON, Principal Investigators (Liverpool Univ) 1 Jun. 1981 4 p Sponsored by NASA ERTS (E82-10203; NASA-CR-168630; NAS 1.26 168630) Avail: NTIS

HC A02/MF A01 CSCL 08G

The data processing of MAGSAT investigator B test tapes and data tapes, and tapes of selected data on 15 magnetically quiet days is reported. The 1980 World Chart spherical model was compared with the MAGSAT (3/80) and MAGSAT vector data were used in the models. An article on modelling the geomagnetic field using satellite data is included. TM.

K. WATSON, S. HUMMER-MILLER, and D. L. SAWATZKY, Principal Investigators 1982 17 p refs Submitted for publication Sponsored by NASA Original contains imagery. Original imagery may be purchased from NASA, Goddard Space Flight Center, (code 601), Greenbelt, Md. 20771. Domestic users send orders to 'Attn: National Space Science Data Center'; non-domestic users send orders to 'Attn World Data Center A for Rockets and Satellites'. HCMM

(E82-10210; NASA-CR-168773) Avail. NTIS HC A02/MF A01 CSCL 05B

Neither iterative registration, using drainage intersection maps for control, nor cross correlation techniques were satisfactory in registering day and night HCMM imagery A procedure was developed which registers the image pairs by selecting control points and mapping the night thermal image to the daytime thermal and reflectance images using an affine transformation on a 1300 by 1100 pixel image. The resulting image registration is accurate to better than two pixels (RMS) and does not exhibit the significant misregistration that was noted in the temperature-difference and thermal-inertia products supplied by NASA. The affine transformation was determined using simple matrix arithmetic, a step that can be performed rapidly on a minicomputer. A.R H.

N82-23584*# Geological Survey, Denver, Colo. GROUND SUPPORT DATA FROM JULY 10 TO JULY 29, 1978, FOR HCMM THERMAL SATELLITE DATA OF THE POWDER **RIVER BASIN, WYOMING**

USGS-OFR-80-469) Avail: NTIS HC A03/MF A01 CSCL 081

Radiometric and meteorological data acquired at three ground stations located approximately 150 km apart in the Powder River Basin, Wyoming, are summarized. The data were collected between July 10 and July 29, 1978, to support the HCMM thermal satellite data acquired during this time period. The parameters measured are direct solar radiance, total solar radiance, sky radiance, air temperature, relative humidity, wind speed, and wind direction A tabulation of the measurement accuracies is presented J.D.

(Contract NAS9-15466; PROJ. AGRISTARS)

(E82-10213; NASA-CR-167508; NAS 1.26:167508, LARS-101481; SR-P1-04194) Avail: NTIS HC A09/MF A01 CSCL 02C

An algorithm is proposed which predicts the optimal features at every node in a binary tree procedure. The algorithm estimates the probability of error by approximating the area under the likelihood ratio function for two classes and taking into account the number of training samples used in estimating each of these two classes. Some results on feature selection techniques, particularly in the presence of a very limited set of training samples, are presented. Results comparing probabilities of error predicted by the proposed algorithm as a function of dimensionality as compared to experimental observations are shown for aircraft and LANDSAT data. Results are obtained for both real and simulated data. Finally, two binary tree examples which use the algorithm are presented to illustrate the usefulness of the procedure. Author N82-23596*# Lockheed Engineering and Management Services Co., Inc , Houston, Tex EVALUATION OF VICAR SOFTWARE CAPABILITY FOR LAND

INFORMATION SUPPORT SYSTEM NEEDS

N. FUKUSHIMA, Principal Investigator 20 Jul. 1981 10 p Sponsored by NASA ERTS (E82-10239, NASA-CR-168755; NAS 1.26:168755, PR-3) Avail:

NTIS HC A02/MF A01 CSCL 05B

The acquisition of tapes which contain vector and scalar data decimated at an interval of 0.5 sec, together with time and position data, is reported. Progress in the study of magnetic anomalies in the vicinity of Japan and in electric currents in the ionosphere and magnetosphere is also reported. MAGSAT data was used in obtaining a map of total force anomaly for the area of latitude 10-70 deg N and longitude 110-170 deg E. One of the outstanding features in the map of the magnetic anomaly is a negative magnetic anomaly in the Okhotsk Sea, which is of geophysical interest because of its possible connection with high heat flow values in that area. NONLINEAR THEORY FOR ELASTIC BEAMS AND RODS AND ITS FINITE ELEMENT REPRESENTATION

J. F. BESSELING Oct. 1981 25 p refs

(WTHD-143) Avail NTIS HC A02/MF A01

Expressions for large curvatures of elastic beams and rods are given in terms of displacement components and angular coordinates. The application of these expressions to bifurcation and stability problems, based on the principle of virtual work is discussed This approach is compared with another finite element representation, and an error in this representation is corrected. The condition of zero extension of the axis in the case of the Euler column is shown to require division into a large number of finite elements in order to ensure an accurate result for the stability coefficient. The conditions of zero extension of the axis and zero curvature about one principal axis of the cross section in the case of the lateral buckling of the end loaded cantilever have similar consequences. MODELS AND MAPS OF THE MAIN FIELD Progress Report J L LEMOUEL, Principal Investigator, C. GIRE, and J. DUCRUIX 1 Apr 1982 13 p refs Sponsored by NASA ERTS (E82-10327; NASA-CR-168906; NAS 1 26:168906) Avail: NTIS HC A02/MF A01 CSCL 08B

The difference between the models comes from the difference in the procedures of data selection and depends on the aim the model is intended for: regional studies necessitates locally higher density of data and for downward continuation the reduction of external variations must be as careful as possible. Refinements of preliminary models MAGP1 and MAGP2 are presented. Models MAGP1 and MAGP2 are found to have drawbacks coming from insufficient reduction of the external variations and from the inhomogeneity in the distribution of the measurement points. New analysis was performed to overcome these shortcomings The quality of the new models is characterized by the average rms of the differences measurement model. тм

MATRIX DATA ANALYSIS: COLOR/B AND W CODING IS NOT ALWAYS ENOUGH Interim Report, 1976 - 1981

M. B. FAINTICH, G. B. SIGLER, and J. D. SIMPSON 1981 31 refs Presented at the Inter-Congr. Symp., Inter. Soc. of Phot and Remote Sensing Comm 3, Otaniemi, Finland, 7-11 Jun. 1982

(AD-A111401) Avail NTIS HC A03/MF A01 CSCL 08B

The Defense Mapping Agency produces digital data bases that describe the physical appearance of the surface of the Earth These data bases include, but are not limited to, terrain elevation, culture including landscape characteristics and vertical features. This data is collected from digitized source maps, from optically or digitally correlated stereo-pairs of photographic imagery, and from digital multi-spectral sensor data. A dramatic impact has been made in the ability to analyze these digital data bases by applying state-of-the-art digital image technology processing and display concepts. These include a variety of color and/or black and white displays of not only intensity/color coded matrix data, but also image processed data using specialized convolution filters, texture discrimination, and special color representation techniques. In addition, computer generated imagery from these data bases serves as a final analysis tool. GRA

(AD-A111307; ETL-R034) Avail: NTIS HC A02/MF A01 CSCL 14E

An inadequate concept of how corresponding points relate to one another on dissimilar images has a greater effect than exposure geometry or data collection on registration problems in stereo photogrammetry Conventional correlation, or one of its relatives, is the measure of similarity used in all automated stereo correlation systems. Correlation, a measure of the linear dependence between two sets of data, is an inadequate measure when there is less than, or more than, a moderate amount of image structure at and around points selected for image matching. The existence of structure should be recognized and utilized in an appropriate manner for image matching Similarly, the absence of structure should be recognized, and the surrounding imagery should be used to complete matches where it is possible. The concurrent determination of what a pixel is, as well as where it is, can alleviate much of the registration problem. A variety of features including point-density data, texture, and edges, as well as existing cartographic knowledge, can be combined and organized through rules in order to more completely describe a point. The overall throughput of the compilation process will be improved in both time and accuracy if those functions which tend to support one another are concurrently, rather than sequentially, performed. If the compilation process takes place in image space, then the image matching operation as well as the other feature extraction operations, can be ordered by the data processing manager to best suit the function of the process Author (GRA)

IS THE NEON COMPOSITION OF OUR SUN, PLANETARY OR SOLAR

M. N. RAO, C. M. NAUTIYAL, and T. R. VENKATESAN (Physical Research Laboratory, Ahmedabad, India) In. International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 141-144. refs

The surficial solar wind from the feldspar grain-size separates of lunar soils is removed by selective chemical etching to determine whether the long term average solar flare Ne composition is planetary or solar. Mineral residues mostly containing solar flare implanted noble gas components are analyzed by step wise gas release mass spectrometric methods. Results do not show any major differences in the Ne ratios of solar flares and solar wind, and the long term average composition of low energy solar flares implanted Ne is similar to solar wind neon instead of planetary, although variations of Ne isotopic ratios in solar flares over short time scales is not ruled out D.L.G.

A82-29541

AN INFRARED EXPOSURE METER

R. W. DANA (U.S. Forest Service, Fort Collins, CO) In: Color aerial photography in the plant sciences and related fields; Proceedings of the Eighth Biennial Workshop, Luray, VA, April 21-23, 1981. Falls Church, VA, American Society of Photogrammetry, 1981, p. 145-156. refs

It is noted that, since the commonly used color infrared aerial film has less latitude to variations in scene brightness than most normal color films, camera exposure adjustment is crucial in the infrared aerial photography of natural resources A description is given of a spotmeter sensitive in the wavelength band of infrared films developed to aid the aerial photographer in adjusting camera settings for optimum exposure of a variety of scenes. Also discussed are airborne tests undertaken to evaluate the meter for agricultural, forest, and range cover. The problems encountered in using photographic photometry to evaluate luminance readings from a hand-held instrument fall into three groups: instrument pointing problems, film sensitometry, and camera calibration. The optimum exposure for quantitative density analysis is thought to be about three-fourths of a stop lower than for visual interpretation. The results of regression analysis suggest that the infrared meter marks an improvement over conventional spotmeters in predicting the infrared response of the film. C.R.

THERMOGRAPHY - A REMOTE SENSING METHOD WITH MANY PERSPECTIVES [THERMOGRAFIE - EINE PERSPEKTIVREICHE FERNERKUNDUNGSMETHODE]

A. GESCHKE (Gesellschaft fuer Internationalen Flugverkehr mbH, Berlin, East Germany) Technisch-oekonomische Information der zivilen Luftfahrt, vol. 17, no. 4, 1981, p 169-171. In German.

Thermography, as considered in this report, is concerned with the utilization of the electromagnetic radiation of the far-infrared region for the formation of images. Possibilities for such a utilization improved greatly with the development of cooled semiconductor sensing devices during the last twenty years. Thermographs were designed as far-infrared image-forming devices which provide a thermal photograph by scanning a far-infrared image of an object or a scene. A description is provided of investigations in which such devices, carried on board of a helicopter or a fixed-wing aircraft, were used to obtain thermal images of an area on the ground. Thermography is found to be a valuable approach for the study of energetic aspects, geologic structures, groundwater budget questions, the vitality of forests and agricultural areas, and water pollution. A82-31019 LARGE AMPLITUDE UNDULATIONS ON THE EQUATORWARD BOUNDARY OF THE DIFFUSE AURORA

A. T. Y. LUI, C.-I. MENG, and S. ISMAIL (Johns Hopkins University, Laurel, MD) Journal of Geophysical Research, vol. 87, Apr 1, 1982, p. 2385-2400. refs

(Contract AF-AFOSR-79-0010, NSF ATM-79-23240; NSF ATM-79-25987)

A description is presented of the first observation of large scale undulations in the equatorward boundary of the diffuse aurora by pictures of global auroral displays in the afternoon-evening sector. These observations are made by a broad band scanning radiometer on the Defense Meteorological Satellite Program (DMSP) satellites. Attention is given to four periods during which the equatorward boundary of the diffuse aurora is undulated. Three of these are taken in the southern polar region and one in the northern polar region. The duration of the undulations is considered along with geomagnetic and interplanetary conditions. All undulations are found to occur during the period of a geomagnetic storm near the peak development of the storm-time ring current. All are accompanied by substorm patterns of discrete auroras.

EXTREMELY HIGH LATITUDE AURORAS

M. S. GUSSENHOVEN (Boston College, Chestnut Hill, MA) Journal of Geophysical Research, vol. 87, Apr. 1, 1982, p. 2401-2412 refs

(Contract F19628-81-K-0032; AF-AFOSR-79-0012)

It is pointed out that imaging devices on the polar orbiting ISIS and Defense Meteorological Satellite Program (DMSP) satellites have greatly increased the extent of polar cap and auroral zone coverage and have prompted several studies of polar cap arcs. A description is presented of a statistical study of the occurrence conditions for arcs recorded in DMSP images at extremely high latitudes, taking into account corrected geomagnetic latitudes equal to or greater than 80 deg. The 80 deg boundary is chosen to minimize the problems associated with defining a polar cap boundary Attention is given to the data base and categorization of extremely high latitude auroras, the relationship to magnetic activity, and the relationship to solar wind conditions. It is found that one category of extremely high latitude auroras is distinctly different from the rest. This category includes the oval auroras which expand poleward in the midnight sector G.R.

A SYSTEM DESIGN FOR A MULTISPECTRAL SENSOR USING TWO-DIMENSIONAL SOLID-STATE IMAGING ARRAYS

R. M. HODGSON (Canterbury, University, Christchurch, New Zealand), F. M CADY (Montana State University, Bozeman, MT), and D PAIRMAN (Department of Scientific and Industrial Research, Physics and Engineering Laboratories, Lower Hutt, New Zealand) IEEE Transactions on Geoscience and Remote Sensing, vol. GE-20, Apr 1982, p. 177-179 Research supported by the University of Canterbury and University Grants Committee. refs

A system developed for remote sensing from light aircraft in the 400-1100 nm wavelength range possesses an architecture which permits the simultaneous capture of up to four images from solid-state, two-dimensional image sensors. In operation, the array sensor captures a series of relatively rapid, approximately 10 msec exposures at intervals as long as 10 sec. This mode of operation has the advantage of nearly the same degree of distortion due to aircraft roll in all image elements. The software generation of sensor drive signals is incorporated in the system. 00

IMAGING SPECTROSCOPY: PROCEEDINGS OF THE SEMINAR. LOS ANGELES, CA, FEBRUARY 10, 11, 1981

D. D. NORRIS, (ED.) (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, CA) Seminar sponsored by SPIE - The International Society for Optical Engineering. Bellingham, WA, SPIE - The International Society for Optical Engineering (SPIE Proceedings. Volume 268), 1981 204 p MEMBERS, \$34.; NONMEMBERS, \$40

The seminar concentrated on the science applications of spectral imaging, multispectral imaging sensors, and spectral filtering. Papers are presented on spectroscopic remote sensing for geological applications, spectral mapping of Jupiter, system design of an interferometer imaging sounder and a common module imaging spectral radiometer. Other topics discussed include the performance and application of an intensified linear self-scanned array instrument, tunable optical filtering using an interferometer for selective modulation, design studies for a spectrally agile staring sensor system, and acousto-optic tunable filters for high-resolution spectral analysis. HIGH SPECTRAL RESOLUTION AIRBORNE SPECTROMETRY

W. COLLINS, S. CHANG, J T. KUO (Columbia University, New York, NY), M. DOUMA, S. MARSHALL (Massachusetts Manufacturing Corp., Cambridge, MA), and P. MURPHY (Sanders Associates, Inc., Nashua, NH) In: Imaging spectroscopy; Proceedings of the Seminar, Los Angeles, CA, February 10, 11, 1981 Bellingham, WA, SPIE - The International Society for Optical Engineering, 1981, p 22-28 (Contract JPL-955832; NSF ENG-78-24432)

An airborne spectroradiometer system developed at Columbia University has been providing new spectral data for use in remote sensing for natural resources. The system has been improved by addition of a solid state silicon detector array, and has been extended into the infrared by addition of a 64 element lead sulfide detector array. The infrared data in the 2000 to 2500 nm region especially holds large potential for mineral and oil exploration.

A82-32447* Santa Barbara Research Center, Goleta, Calif. THEMATIC MAPPER - AN OVERVIEW OF SPECTRAL BAND REGISTRATION

W. H. FREUDENSTEIN (Santa Barbara Research Center, Goleta, CA) In: Imaging spectroscopy; Proceedings of the Seminar, Los Angeles, CA, February 10,11, 1981 Bellingham, WA, SPIE - The International Society for Optical Engineering, 1981, p. 50-63. (Contract NAS5-24200)

The Thematic Mapper (TM) is a high-resolution radiometer designed for earth resources classification and mapping. The TM employs multispectral scanning in a near polar orbit to sweep a 185-km swath. Data are obtained through a combination of spacecraft motion and the sweeping action of the scan mirror.

08 INSTRUMENTATION AND SENSORS

These data are transmitted either directly to around stations around the world or through a relay to the central data processing facility at White Sands, NM Seven spectral passbands are employed, and applications include coastal water mapping, soil vegetation differentiation, biomass surveys, water body delineation, vegetation moisture measurement, plant heat stress management, and hydrothermal mapping Attention is given to the scan mirror assembly, scan nonlinearities, the characterization and compensation of scan profiles, experimental performance, and a procedure for midscan correction. (Contract NAS7-100)

An instrument concept that uses solid-state array imaging has been developed for a future land observing system. The design concept is responsive to a variety of use needs and provides improved capabilities over the planned Landsat Thematic Mapper A comparison of the differing approaches to the instrument design was made, resulting in the selection of a concept which uses a spectrograph coupled to a line-array imager to provide simultaneous spatial and spectral resolution. The design provides an inherent solution to the problem of achieving precise registration among the spectral bands Data processing on the focal plane is used to select the spectral bands and their band widths Onboard capabilities include radiometric correction, selection of instantaneous field-of-view and swath width, and data (Author) compression

DIFFRACTION-LIMITED FROM INVERSION DATA OF MULTIWAVELENGTH REMOTE SENSORS, II - NONLINEAR DEPENDENCE OF OBSERVABLES ON THE GEOPHYSICAL PARAMETERS

P. W. ROSENKRANZ (MIT, Cambridge, MA) Radio Science, vol. 17, Jan -Feb. 1982, p. 245-267. refs

(Contract NAS5-22929, NAG5-10)

Linear shift-invariant spatial filtering is applied to inversion of radiometric measurements of the earth in both polarizations at the following frequencies: 6.6, 10.7, 18, 21, and 37 GHz. For purposes of radiative transfer calculations at these frequencies, the state of the ocean-atmosphere system is described by a seven-parameter model. The parameters are near-surface wind speed, sea surface temperature, integrated water vapor mass, scale height of water vapor in an exponential distribution, integrated liquid water mass, height of the liquid water, and characteristic drop radius in a Best (1950) drop size distribution. Also described is a spatial filtering algorithm by means of which geophysical parameters are retrieved from measurements made over the ocean by the scanning multichannel microwave radiometer on the Nimbus satellite. The parameters here are near-surface wind speed, sea surface temperature, rain rate, integrated atmospheric water vapor content, and integrated liquid water content (including rain). CR

AN OPTICAL OBJECTIVE LENS FOR EARTH OBSERVATIONS BY SATELLITES [UN OBJECTIF OPTIQUE POUR L'OBSERVATION DE LA TERRE A PARTIR DE SATELLITES] E. MATHIEU (Wild Heerbrugg AG, Heerbrugg, Switzerland), E. SEIN (Centre National d'Etudes Spatiales, Centre Spatial de Toulouse, Toulouse, France), and J.-P. DURPAIRE (ESA, Toulouse, France) ESA Journal, vol. 6, no. 1, 1982, p. 71-81. In French. European Space Agency

(Contract ESA-4422/80)

The features and performance of objective lenses intended for transmission of optical images of the earth to deposition on the detectors of CCDs onboard the ESA land application satellite system/optical imaging instrument are described. Trials to determine satisfactory durability for space-based uses are reviewed The lenses were required to have an angular field of 16 deg, a 105 mm aperture, cover the spectral bands 0.6, 0.69, 0.8, and 0.9 micron, the panchromatic band from 0.52-0.9 micron, have a focal distance to within 3 mm of 567 mm, cause less than 1 percent distortion in the image size, and less than 1.5 micron error in the spectral domain Other requirements were for a 0.75 transmittance, polarization less than 1 percent, and a modulation transfer function close to theoretical limits, which was realized at less than 1 mm. The objective produced will have a resolution of around 15 m at the earth's surface from an orbit of 681 km and a total field of view of 167 km. M.S.K.

QUANTITATIVE RELATIONSHIPS OF NEAR-SURFACE SPECTRA TO LANDSAT RADIOMETRIC DATA

S. E. MARSH and R. J. P LYON (Stanford University, Stanford, CA) Remote Sensing of Environment, vol. 10, Dec. 1980, p 241-261. Research supported by the U.S. Geological Survey. refs

It is shown that for typical homogeneous and moderately heterogeneous terrains, the number of samples required for estimating the mean reflectance of a pixel is small. No more than 9-20 samples are required to be within 2% reflectance at the 95% probability level. Coincident field measurements and satellite observations are used to test the equivalency and correlation of the reflectance data. It is noted that, before the Landsat data could be compared with the surface measurements, the satellite brightness values had to be converted to absolute radiometric units and corrected for atmospheric attenuation and scattering. A conversion method using a standard/target comparison, which indirectly compensates for atmospheric attenuation and scattering, produces a Landsat equivalent reflectance exhibiting a root-mean-square error of + or - 4% reflectance (compared with the surface measured value at 12 test sites). SNOWPACK MONITORING IN NORTH AMERICA AND EURASIA USING PASSIVE MICROWAVE SATELLITE DATA

J L. FOSTER, A. RANGO, D. K. HALL, A. T. C. CHANG, L. J. ALLISON, and B. C DIESEN, III (NASA, Goddard Space Flight Center, Greenbelt, MD) Remote Sensing of Environment, vol 10, Dec. 1980, p. 285-298. refs

Areas of the Canadian high plains, the Montana and North Dakota high plains, and the steppes of central Russia have been studied in an effort to determine the utility of spaceborne microwave radiometers for monitoring snow depths in different geographic areas. Significant regression relationships between snow depth and microwave brightness temperatures were developed for each of these homogeneous areas. In each of the study areas investigated in this paper. Nimbus-6 (0.81 cm) ESMR data produced higher correlations than Nimbus-5 (1.55 cm) ESMR data in relating microwave brightness temperature to snow depth. It is difficult to extrapolate relationships between microwave briahtness temperature and snow depth from one area to another because different geographic areas are likely to have different snowpack conditions. INFERENCE OF REFRACTIVITY PROFILES BY SATELLITE-TO-GROUND RF MEASUREMENTS

K. D ANDERSON (U.S Naval Ocean Systems Center, San Diego, CA) Radio Science, vol. 17, May-June 1982, p. 653-663 refs

A technique is described to infer an estimate of the tropospheric radio refractive index distribution from earth-based observations of a satellite-born beacon. This technique, known as the direct inference technique (DIT) predicts the refractivity profile by comparing the observed interference pattern, created as the satellite moves through low elevation angles, to patterns generated from a family of assumed refractivity profiles It is shown that DID correctly predicts the ducting environment for 12 of 22 satellite-to-ground RF measurements made during July and August 1978. Although the inferred profile geometry can differ significantly from the refractivity profile measured by an upper air sounding, the technique is moderately successful in predicting whether the true profile contains a ground-based or elevated duct. However, the overall reliability of predicting the dominant features of the duct (e.g., refractive gradient through the trapping layer, top height of the duct) is not adequate for operational usage. IRRADIANCE MEASUREMENT ERRORS DUE TO THE ASSUMPTION OF A LAMBERTIAN REFERENCE PANEL

D S. KIMES and J. A KIRCHNER (NASA, Goddard Space Flight Center, Earth Resources Branch, Greenbelt, MD) Remote Sensing of Environment, vol. 12, May 1982, p. 141-149. refs A technique is presented for determining the error in diurnal

A technique is presented for determining the error in diurnal irradiance measurements that results from the non-Lambertian behavior of a reference panel under various irradiance conditions. Spectral biconical reflectance factors of a spray-painted barium sulfate panel, along with simulated sky radiance data for clear and hazy skies at six solar zenith angles, were used to calculate the estimated panel irradiances and true irradiances for a nadir-looking sensor in two wavelength bands. The inherent errors in total spectral irradiance (0.68 microns) for a clear sky were 0.60, 6.0, 13.0, and 27.0% for solar zenith angles of 0, 45, 60, and 75 deg, respectively. The technique can be used to characterize the error of a specific panel used in field measurements, and thus eliminate any ambiguity of the effects of the type, preparation, and aging of the paint. TÉCHNICAL AND ECONOMICAL CHARACTERISTICS OF THE AFA-TES-10M AERIAL CAMERA [TEKHNIKO-EKONO-MICHESKIE POKAZATEL! AEROFOTOAPPARATA AFA-TES-10M]

A G. VANIN Geodeziia i Kartografiia, Apr. 1982, p. 36-39. In Russian refs

technical characteristics and economics of the The AFA-TES-10M aerial camera are compared with those of the AFA-TES-100M camera which it replaces. Although a focal length of 100 mm makes both suitable for large-scale cartography, the newer camera, which makes use of a Russar-71 objective, exhibits reduced objective distortion and increased resolution in comparison with the AFA-TES-100M. A shorter operating cycle and an extended exposure range also allow a wider applicability and greater effectiveness in large-scale cartography. Analysis of the costs involved in producing topographic maps of a rolling terrain at various scales by the AFA-TES-10M indicates an overall savings as a result of reductions in labor costs, the amount of field validation and cameral photogrammetric processes required and specific capital investment, as well as an increase in the productivity of survey work. Development costs of the new system would be recovered typically in two years. ALW.

SENSITOMETRY IN CANADIAN AERIAL SURVEY

P D. CARMAN (National Research Council, Ottawa, Canada) In: American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers Falls Church, VA, American Society of Photogrammetry, 1981, p. 285-295. refs

Since 1943, sensitometric control of the processing of aerial negatives has been used by the Royal Canadian Air Force (RCAF) in connection with the performance of its task to provide aerial photography for Canada. The sensitometers used by the RCAF suffered from a variety of problems which, however, could be overcome by making use of repair and recalibration facilities. The transfer of aerial photography assignments from the RCAF to a number of private companies in the 1950's made it appear desirable to employ sensitometers which could perform reliably without easy access to specialized repair facilities. Attention is given to a sensitometer which was designed to satisfy these requirements The design features of the new instrument are discussed, taking into account the light source, the spectral quality of illumination, the shutter, and the electrical supply. Aspects of sensitometer

08 INSTRUMENTATION AND SENSORS

calibration and verification are considered along with the uses of sensitometric control of aerial photography in Canada G.R

A82-34727 REMOTE SENSING OF THERMAL SUBSURFACE TERRAIN PROPERTIES

F. E. ALZOFON (Boeing Aerospace Co., Seattle, WA) In: American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p. 335-341. refs

It is noted that although the sensed radiation is generated and limited by heat flow through the material underlying the emitting surface. little attention appears to have been paid to the effect of variation in properties of the conducting materials on the information carried by the emitted radiation. As a consequence, variations in thermal radiation may be attributed solely to variation of the temperature and emissivity of the radiating surface. However, it is shown that variation in radiant emittance can equally well be dominated by variation in the thermal conductivity of the underlying material. Criteria are derived under which either thermal conductivity variations or emissivity variations dominate radiant emittance data. A definition is given of threshold temperature; below the threshold, emissivity variations dominate, above it thermal conductivity variations dominate. Expressions are presented for the threshold temperature for various kinds of surface cooling CR.

A82-34737

AN OPTICAL DATA LINK FOR AIRBORNE SCANNING SYSTEM

M. J. GREEN (Wisconsin, University, Madison, WI) In: American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p. 476-482.

In connection with a study of oceanic thermal fronts, the Navy is interested in a thermal scanning system which could be used with their P-3 patrol aircraft. A suitable scanning system would be the RS-18A scanning thermal IR radiometer. However, an obstacle regarding the envisaged use of the instrument is related to the necessity to employ the aircraft without an introduction of any modifications. The obstacle has been overcome by making use of an optical data link which replaces the hardwire connections between the scanner and the power supply. The optical link is housed in a ten inch diameter tube which is clamped in position directly behind the scanner head G.R.

THE USE OF SKYLAB S-190B PHOTOGRAPHY FOR SMALL SCALE MAPPING

I. M. EL-HASSAN (Riyadh, University, Riyadh, Saudi Arabia) In: American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p. 536-543 refs

The use of the Skylab Earth Terrain Camera (S-190B) with 1:946,000 scale photography in small-scale mapping is investigated. The procedure used in making the measurements on the Skylab imagery is described An analytical absolute orientation is performed, and the results show that the photography could be used for mapping at scales of 1:100,000 and smaller. The photography used in the test comprises a strip of three photographs exposed on the SO-242 high-resolution color film. Second generation film transparencies made from the original film are used in the actual test.

A82-34746

COMPARISONS OF LAND COVER CLASSIFICATIONS FROM SELECTED REMOTE SENSING SYSTEMS

J B. CAMPBELL (Virginia Polytechnic Institute and State University, Blacksburg, VA) and F M. HENDERSON (New York, State University, Albany, NY) In: American Society of Photogrammetry, Annual Meeting, 47th, Washington, DC, February 22-27, 1981, ASP Technical Papers. Falls Church, VA, American Society of Photogrammetry, 1981, p. 618-626. refs

The present investigation is concerned with differences in accuracy of land cover maps generated by manual interpretation of several forms of remote sensing imagery. An area near Harrisburg, PA was imaged by K-band SLAR, the Landsat-1 MSS, the Landsat-3 RBV, and two Seasat SAR passes These images were manually interpreted to yield land cover parcels corresponding to the Level I categories considered by Anderson et al. (1976). The resulting interpretations were compared with the more detailed USGS land cover map of the same region to determine classification errors It is pointed out, however, that the results of this comparison cannot be interpreted as definitive assessments of the merits of each sensor system Continued research is necessary According to the current study, airborne radar imagery produced the best overall accuracy With respect to the four space-borne sensor systems the MSS and RBV images are preferable to the digitally processed Seasat SAR image with the optically processed Seasat SAR image being the least accurate system product. G.R.

A82-36018

THE USE OF MICROWAVE RADIOMETRY FOR THE DETERMINATION OF SNOW COVER HEIGHT [ISPOL'ZOVANIE SVCH RADIOMETRII DLIA OPREDELENIIA VYSOTY SNEZHNOGO POKROVA]

V. E. GERSHENZON, V. G. IRISOV, IU B. KHAPIN, and V S. ETKIN (Akademiia Nauk SSSR, Institut Kosmicheskikh Issledovanii, Moscow, USSR) Akademiia Nauk SSSR, Doklady, vol. 264, no. 3, 1982, p. 601-603. In Russian. refs

A method is proposed for determining the height of snow cover from remote measurements of the brightness temperatures in the wavelength range 1.5-0.34 cm. The method is validated by means of a model experiment and by comparing the results with direct measurements. The remote and direct measurements are found to correlate to within 5 cm. V.L.

MICROWAVE SENSING FROM SPACE

H. SCHUESSLER (Dornier System GmbH, Friedrichshafen, West Germany) American Astronautical Society and Deutsche Gesellschaft fuer Luft- und Raumfahrt, Goddard Memorial Symposium on Spacelab, Space Platforms and the Future, 20th, Greenbelt, MD, Mar. 17-19, 1982, AAS 15 p. Research supported by the Bundesministerium fuer Forschung und Technologie (AAS PAPER 82-127)

The design, functions, and performance of satellite microwave sensor systems for earth imaging are described. It is noted that microwave operations can be carried out in all weather and in day or night conditions, and that current satellite systems operate in the interval of 1-20 GHz. Applications for soil characterization, moisture, and wind vector measurements over the sea are described in terms of frequency selection, power, and antenna requirements. Sunsynchronous orbits offer the advantage of low power storage capabilities due to avoidance of eclipse conditions. Areas of development necessary to implement an SAR for GEO positioning are reviewed, and features of a microwave remote sensing experiment involving SAR operating at 96 GHz during the first Spacelab flight on the Shuttle are presented. Finally, details of the ERS-1 satellite, which will carry a radar altimeter, wind scatterometer, and SAR are outlined M.S.K.

SOLID STATE INSTRUMENTATION CONCEPTS FOR EARTH RESOURCE OBSERVATION

H. L. RICHARD (NASA, Goddard Space Flight Center, Advanced Land Observing Systems Studies Office, Greenbelt, MD) American Astronautical Society and Deutsche Gesellschaft fuer Luft- und Raumfahrt, Goddard Memorial Symposium on Spacelab, Space Platforms and the Future, 20th, Greenbelt, MD, Mar. 17-19, 1982, AAS 18 p refs

(AAS PAPER 82-132)

Late in 1980, specifications were prepared for detail design definition of a six band solid state multispectral instrument having three visible (VIS), one near infrared (NIR), and two short wave infrared (SWIR) bands. This instrument concept, known as the Multispectral Linear Array (MLA), also offered increased spatial resolution, on board gain and offset correction, and additional operational modes which would allow for cross track and stereoscopic viewing as well as a multialtitude operational capability. A description is presented of a summary of some of the salient features of four different MLA design concepts, as developed by four American companies. The designs ranged from the use of multiple refractive telescopes utilizing three groups of focal plane detectors electronic correlation processing for achieving spatial registration, and incorporating palladium silicide (PdSi) SWIR detectors, to a four-mirror all-reflective telecentric system utilizing a beam splitter for spatial registration. SEASAT: A SATELLITE SCATTEROMETER ILLUMINATION TIMES OF SELECTED IN SITU SITES

L. C. SCHROEDER, D. R. GOODRIDGE, J. C. BOBERLY, J. K. HUGHES, and J. L. SWEET Mar. 1982 120 p

(NASA-TM-83280; NAS 1.15:83280) Avail: NTIS HC A06/MF A01 CSCL 08J

A list of times that the SEASAT A Satellite Scatterometer (SASS) illuminated from directly above or directly abeam, selected surface sites where in situ winds were measured is provided. The list is ordered by the Greenwich Mean Time (GMT) of the midpoint of the illumination period (hit time) for a given surface site. The site identification, the orbit number and the direction from the subtrack in which the truth lies are provided. The accuracy of these times depends in part upon the ascending node times, which are estimated to be within + 1 sec, and on the illumination time relative to the ascending node, which is estimated to be within +6 seconds. The uncertainties in the times provided were judged to be sufficiently small to allow efficient and accurate extraction of SASS and in situ data at the selected surface sites. The list contains approximately six thousand hit times from 61 geographically dispersed sites. Author N82-24264# Joint Publications Research Service, Arlington, Va. PURPOSE, BACKGROUND OF 'INTERCOSMOS-21' MISSION M. A. RIMSHA *In its* USSR Rept. Space, No 15 (JPRS-80424) p 94-98 29 Mar. 1982 Transl. into ENGLISH from Zemlya Vselennaya (USSR), no. 5, Sep. - Oct. 1981 p 39-41 Avail: NTIS HC A07/MF A01

Research performed with satellies of the 'Intercosmos' series is discussed. Scientists have investigated short wave emissions of the Sun and the Earth's ionosphere and magnetosphere, cosmic rays and meteorite flows. Various technical systems were tested in these satellites. A transmitter of the 'beacon' type operated successfully in the first 'Intercosmos' satellites, while a special telemetric system later functioned in space and was recommended for further use. The unified telemetric system transmitted information directly to ground stations without the use of spacecraft instruments. S.L

ANTIPROTONS FROM GALACTIC SOURCES OF COSMIC RAYS AND GAMMA RAYS

R COWSIK (Franklin Institute, Bartol Research Foundation, Newark, DE; Tata Institute of Fundamental Research, Bombay, India) and T. K GAISSER (Franklin Institute, Bartol Research Foundation, Newark, DE) In International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 2 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 218-221. Research supported by the US Department of Energy. refs

Recent observations of discrete galactic sources of gamma rays are examined in terms of a modified version of the nested leaky box model of Cowsik and Wilson (1973, 1975). It is shown that the modified model can account for the observed high fluxes of antiprotons The essential idea is that bright gamma-ray sources are surrounded by significantly more matter than most other sources of cosmic rays, they are thus strong sources of both secondary gamma rays and antiprotons, and at the same time efficient absorbers of heavy nuclei V.L.

ANGULAR VARIATIONS OF NONTHERMAL RADIO EMISSION FROM THE GALAXY RELEVANT TO THE STRUCTURE OF INTERSTELLAR MAGNETIC FIELD

G. V. CHIBISOV (Akademia Nauk SSSR, Fizicheskii Institut, Moscow, USSR) and V. S. PTUSKIN (Akademia Nauk SSSR, Institut Zemnogo Magnetizma, Ionosfery i Rasprostranenia Radiovoln, Troitsk, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers Volume 2. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 233-235.

The relation between the correlation function of the intensity of galactic radio-emission at different directions and the correlation function of interstellar magnetic field at different points is found. This relation is shown to be used for the determination of random and regular components of magnetic field. Measurements at different frequencies clarify the character of cosmic ray propagation in the Galaxy, and in particular, distinguish between the diffusive and convective transfer of cosmic rays. ON THE PHYSICAL SENSE OF THE CONSTANT OF SOLAR COSMIC RAY CORONAL PROPAGATION

G. A. BAZILEVSKAIA (Akademiia Nauk SSSR, Fizicheskii Institut, Moscow, USSR) and E. V VASHENIUK (Akademiia Nauk SSSR, Poliarnyi Geofizicheskii Institut, Apatity, USSR) In International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3. Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 93-96. refs

An analysis is made of the time dependence of solar cosmic ray intensity and anisotropy Results show that the coronal time is the time of the escape of the bulk of the particles into the interplanetary space, and it is found that the generation of solar cosmic rays is almost simultaneous in the fast propagation region, which could be in the case of solar cosmic ray acceleration by the quasi-spheric shock wave This result is in agreement with values found by Bazilevskaya and Vashenyuk (1979) for the transit time of the first particles in the corona for high energy solar cosmic rays. DLG

A82-22603

THE INFLUENCE OF THE SECTOR STRUCTURE OF INTERPLANETARY MAGNETIC FIELD ON THE SOLAR COSMIC RAY CHARACTERISTICS

G. A. BAZILEVSKAIA (Akademia Nauk SSSR, Fizicheskii Institut, Moscow, USSR) In: International Cosmic Ray Conference, 17th, Paris, France, July 13-25, 1981, Conference Papers. Volume 3 Gif-sur-Yvette, Essonne, France, Commissariat a l'Energie Atomique, 1981, p. 117-120. refs

A statistical study of solar cosmic-ray events from 1957 to 1968 is performed, taking into account only events with certain or probable association. The solar wind velocity is used to define the earth connection longitude on the sun and to map the longitude of sector boundaries. No sector boundary influence on registration probability of solar cosmic-rays is found, and the intensity time dependence seems to be controlled by coronal structures, which are situated lower in the solar atmosphere than where the sector boundaries are formed D.L.G.

THE USE OF THE SPOT SATELLITE IN NATURAL RESOURCE EVALUATION [EL SATELITE SPOT EN LA EVALUACION DE LOS RECURSOS NATURALES]

P.-M. ADRIEN CIDA, vol. 5, no 5, 1980, p. 31-36 In Spanish.

The practical application of the remote sensing satellite SPOT to natural resources assessment in Latin America are discussed SPOT, which will be launched by the French government in 1984, will assume a nearly polar orbit at an altitude of 822 km and be able to scan a 60 km-wide area with 10-20 m sweeps of its multispectral scanner. Comparisons are made with the capabilities

of the ARGOS satellite, which has been in operation since 1974. The data to be collected by SPOT will be pertinent to research in agricultural land use, agricultural meteorology, hydrology, forest management, and mineralogical resources. Attention is given to the coordination of such research and the dissemination of its data by French government agencies. OC.

A82-33555

REMOTE SENSING OF THE EARTH'S RESOURCES - THE SOVIET EXPERIENCE

J. POPESCU British Interplanetary Society, Journal (Space Chronicle), vol. 35, June 1982, p. 273, 274.

The tools, techniques, and targets of Soviet remote sensing systems are explored. Satellite viewing results are rechecked by both aerial surveys and surface sampling for purposes of calibration and confirmation. A total of 1,260 Kosmos spacecraft were launched by 1979, and carried vidicons and microwave sensors for data acquisition. The Salyut space stations were also equipped with a multispectral scanner which featured 10 m resolution, could discern between wet and dry ground, and covered the range 0.46-0.89 microns. Additional instrumentation comprised a radio telescope, stereoscopic camera, and SAR. World grain crops are monitored to anticipate the world wheat market, regions of intense storm activity such as the Bermuda Triangle are studied, and weather conditions and evolution, particularly in Arctic shipping areas, are tracked Telemetry stations are located in five countries outside the Soviet Union. Instances of successful cosmonaut remote sensing for mineral prospecting, glacier mapping, and sea ice tracking to protect ocean-going vessels are cited. M.S.K.

EARTH OBSERVATIONS FROM SPACE - TRENDS AND PROSPECTS

G BRACHET (Centre National d'Etudes Spatiales, Paris, France) In: International aerospace review, Proceedings of the First International Aerospace Symposium, Le Bourget, Seine-Saint-Denis, France, June 2, 3, 1981. New York, American Institute of Aeronautics and Astronautics, 1982, p. 215-223.

The instrumentation and missions of various earth observation satellites are outlined. Earth observation satellites are grouped into experimental types for testing instruments or observing techniques, operational meteorological satellites with on-line users, the Landsat series of satellites for performing whole-earth scanning using different EM wavelengths, and ocean and ice scanning satellites. The Tiros-N series of satellites included advanced very high resolution radiometers for sea-surface temperature measurements, a solar backscatter ultraviolet sensor for global ozone monitoring, and an advanced microwave sounding unit The GOES-D spacecraft carries an improved imaging radiometer for atmospheric vertical sounding, while the European Meteosat features a water vapor channel at 6-7 microns for upper atmosphere water vapor content assays. Landsat data has been useful in areas such as agriculture, forestry, urban planning, mapping, cartography, water resources studies, and geology. M S.K.

A82-34367#

ERS-1 EUROPEAN REMOTE SENSING SATELLITE

Dornier-Post (English Edition), no. 2, 1982, p. 24-29

The mission objectives and the components developed for the ERS-1 remote sensing satellite are discussed. The spacecraft is intended for use in weather forecasting, sea state forecasting, off-shore activities support, ship routing, ice monitoring, ocean pollution monitoring, scientific investigations of complex ocean interactions, and microwave sensing of land surfaces and coastal zones. A supply module provides power for the instruments and earth pointing. The data will be transmitted and possibly stored on board. Launched by the Ariane into a 675 km sunsynchronous orbit, ERS-1 will carry a sidelooking radar with SAR for high resolution land and ocean imaging and wave spectra plotting, and a wind scatterometer for measurements from 4-24 m/sec over the oceans A microwave radar serves for wave height, earth surface height, wind speed, and iced- or open-ocean determination. Launch is scheduled for 1987.

SPACE SCIENCE FOR APPLICATIONS - THE HISTORY OF LANDSAT

P. E MACH In. Space science comes of age Perspectives in the history of the space sciences; Proceedings of the Symposium, Washington, DC, March 23, 24, 1981 Washington, DC, Smithsonian Institution Press, 1981, p 135-148. NASA-supported research refs

The history of the Landsat project is discussed in terms of three historical phases, each characterized by a dominant problem. From 1964 to 1967, the challenge was to develop interagency cooperation and to achieve consensus on basic plans for the satellite Between 1968 and 1971, the cooperating agencies had to persuade the Bureau of the Budget to provide funding for the project Since 1972, the challenge to NASA has been to encourage applications of the Landsat data and plan the shift from an experimental program to an operational one. The tension between experimental and operational goals has run through all these phases, and the conflicts between agencies is detailed, as well as the interaction between technological and political systems.

An economic evaluation of space based observation systems is presented. The cost effectiveness of these satellite systems is discussed.

N82-24568*# National Conference of State Legislatures, Denver, Colo Remote Sensing Project.

A LEGISLATOR'S GUIDE TO LANDSAT

1982 33 p Sponsored by NASA. Original contains color imagery Original photography may be purchased from the EROS Data Center, Sioux Falls, S.D. 57198 ERTS

(E82-10290; NASA-CR-168859, NAS 1.26[.]168859) Avail: NTIS HC A03/MF A01 CSCL 05B

The LANDSAT satellite is an effective tool in meeting the natural resources data requirements of state and federal legislation. The

availability of data from the satellite is beginning to have an impact on state legislature activities. An overview of the history, operation, and data analysis techniques, is presented as well as a discussion of the advantages and limitations of this method of remote sensing. Applications are discussed in the areas of (1) land resource planning and management; (2) coastal zone management; (3) agriculture; (4) forestry; (5) routing and siting, (6) environmental monitoring; and (7) geological exploration. National and state sources from which information about LANDSAT technology is available are listed.

N82-26746*# Purdue Univ., Lafayette, Ind. Lab. of Applications of Remote Sensing.

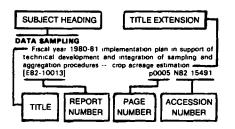

KEY ISSUES IN THE ANALYSIS OF REMOTE SENSING DATA: A REPORT ON THE WORKSHOP

P. H. SWAIN, Principal Investigator Jun 1981 41 p Workshop held in West Lafayette, Ind., 22-23 Jun. 1981 ERTS (Contract NAS9-15466)

(E82-10348; NASA-CR-167570; NAS 1.26:167570;

LARS-TR-062481) Avail NTIS HC A03/MF A01 CSCL 05B

The procedures of a workshop assessing the state of the art of machine analysis of remotely sensed data are summarized. Areas discussed were, data bases, image registration, image preprocessing operations, map oriented considerations, advanced digital systems, artificial intelligence methods, image classification, and improved classifier training Recommendations of areas for further research are presented. J D. Typical Subject Index Listing

The subject heading is a key to the subject content of the document. The title is used to provide a description of the subject matter. When the title is insufficiently descriptive of the document content, the title extension is added, separated from the title by three hyphens The (NASA or AIAA) accession number and the page number are included in each entry to assist the user in locating the abstract in the abstract section (of this supplement) If applicable, a report number is also included as an aid in identifying the document. Under any one subject heading, the accession numbers are arranged in sequence with the AIAA accession numbers appearing first

CONTRACT NUMBER INDEX

EARTH RESOURCES / A Continuing Bibliography (Issue 35)

OCTOBER 1982

Typical Contract Number Index Listing

Listings in this index are arranged alphanumencally by contract number. Under each contract number, the accession numbers denoting documents that have been produced as a result of research done under that contract are arranged in ascending order with the AIAA accession numbers appearing first The accession number denotes the number by which the citation is identified in the abstract section. Preceding the accession number is the page number on which the citation may be found

Typical Report/Accession Number

Index Listing

Listings in this index are arranged alphanumencally by report number. The page number indicates the page on which the citation is located. The accession number denotes the number by which the citation is identified. An asterisk (*) indicates that the item is a NASA report. A pound sign (#) indicates that the item is available on microfiche

REPORT NUMBER INDEX

ACCESSION NUMBER INDEX

EARTH RESOURCES / A Continuing Bibliography (Issue 35)

OCTOBER 1982

Typical Accession Number Index Listing

Listings in this index are arranged alphanumencally by accession number. The page number listed to the right indicates the page on which the citation is located. An asterisk (*) indicates that the item is a NASA report. A pound sign (#) indicates that the item is available on microfiche.

16. Abstract						
This bibliography list 587 reports, articles, and other documents introduced into the NASA Scientific and Technical Information System between July 1, and September 30, 1982. Emphasis is placed on the use of remote sensing and geophysical instrumentation in spacecraft and aircraft to survey and inventory natural resources and urban areas. Subject matter is grouped according to agriculture and forestry, environmental changes and cultural resources, geodesy and cartography, geology and mineral resources, hydrology and water management, data processing and distribution systems, instrumentation and sensors, and economic analysis.

PUBLIC COLLECTIONS OF NASA DOCUMENTS

DOMESTIC

NASA distributes its technical documents and bibliographic tools to eleven special libraries located in the organizations listed below. Each library is prepared to furnish the public such services as reference assistance, interlibrary loans, photocopy service, and assistance in obtaining copies of NASA documents for retention.

CALIFORNIA University of California, Berkeley COLORADO University of Colorado, Boulder DISTRICT OF COLUMBIA Library of Congress GEORGIA Georgia Institute of Technology, Atlanta ILLINOIS The John Crerar Library, Chicago MASSACHUSETTS Massachusetts Institute of Technology, Cambridge MISSOURI Linda Hall Library, Kansas City NEW YORK Columbia University, New York OKLAHOMA University of Oklahoma, Bizzell Library PENNSYLVANIA Carnegie Library of Pittsburgh WASHINGTON University of Washington, Seattle

NASA publications (those indicated by an '*' following the accession number) are also received by the following public and free libraries

CALIFORNIA Los Angeles Public Library San Diego Public Library COLORADO Denver Public Library CONNECTICUT Hartford Public Library MARYLAND Enoch Pratt Free Library, Baltimore MASSACHUSETTS Boston Public Library MICHIGAN Detroit Public Library MINNESOTA Minneapolis Public Library and Information Center **NEW JERSEY** Trenton Public Library

NEW YORK Brooklyn Public Library Buffalo and Erie County Public Library Rochester Public Library New York Public Library OHIO Akron Public Library Cincinnati and Hamilton County Public Library Cleveland Public Library Dayton Public Library Toledo and Lucas County Public Library TEXAS Dallas Public Library Fort Worth Public Library WASHINGTON Seattle Public Library WISCONSIN Milwaukee Public Library

An extensive collection of NASA and NASA-sponsored documents and aerospace publications available to the public for reference purposes is maintained by the American Institute of Aeronautics and Astronautics. Technical Information Service. 555.West 57th Street 12th Floor New York. New York 10019

EUROPEAN

An extensive collection of NASA and NASA-sponsored publications is maintained by the British Library Lending Division Boston Spa Wetherby Yorkshire England By virtue of arrangements other than with NASA, the British Library Lending Division also has available many of the non-NASA publications cited in *STAR* European requesters may purchase facsimile copy of microfiche of NASA and NASA-sponsored documents those identified by both the symbols # and * from ESA - Information Retrieval Service European Space Agency 8-10 rue Mario-Nikis, 75738 Paris CEDEX 15 France
