SeaSat A Satellite Scatterometer Illumination
Times of Selected In Situ Sites

by

J. Kenrick Hughes¹, and Jon L. Sweet³

ABSTRACT

This publication provides a list of times that the SeaSat A Satellite Scatterometer (SASS) illuminated from directly above or directly abeam, selected surface sites where insitu winds were measured. The list is ordered by the Greenwich Mean Time (GMT) of the midpoint of the illumination period (hit time) for a given surface site. The list provides the site identification, the orbit number and the direction from the subtrack in which the truth lies.

The accuracy of these times depends in part upon the ascending node times, which are estimated to be within ± 1 sec, and on the illumination time relative to the ascending node, which is estimated to be within ± 6 seconds. The list provides each of these times also, to allow for more precise updates. The uncertainties in the times provided were judged to be sufficiently small to allow efficient and accurate extraction of SASS and in situ data at the selected surface sites. The list contains approximately six thousand hit times from 61 geographically dispersed sites.

Introduction

On July 10, 1978, the NASA launched SeaSat A, a satellite designed to demonstrate the utility of microwave remote sensors to measurement of the ocean surface parameters. This satellite made systematic remote measurements of several parameters for one-hundred days, until its premature failure on October 10, 1979. As a part of the evaluation of the SeaSat A Satellite Scatterometer (SASS) wind sensor (Ref. 1-5), corresponding colocated and contemporary surface insitu were sought in order to assess and improve the accuracy of the satellite measurements. Small quantities of colocated data have been successfully gathered for a series of workshops (Ref. 6, 7, 8) but these data were abbreviated in time and geographic area.

The effort described herein was to determine all times during the SASS lifetime when SASS measurements were taken in the vicinity of selected high-quality in situ measurement sites. This was accomplished by displaying the SeaSat orbit and measurement swath and the surface sites on an interactive graphics computer terminal to determine when they overlaid each other. The times when the satellite was in radar range and directly overhead or abeam of the site were recorded and have been listed herein. These times correspond to the mean of the times that measurements of normalized radar cross section (NRCS) were made at the site from the forward and aft SASS beams, which are separated by 1.89 sec (at nadir) to about 3 minutes (at 1350 km off the subtrack).

Procedure

The sites of this study were limited to stationary locations where for the SeaSat period, quality calibrated surface measurements were made periodically. These sites consist of the North American data buoys, weather stations, certain petroleum and commercial research towers, 4 Japanese data buoys, and 13 Australian buoys (see Table I). Figures 1 and 2 show the location of these surface measurement sites, which are most heavily concentrated in the region around the United States. Other surface sites (such as moving oceanographic ships or ships of opportunity) were not investigated because of increased complexity.

The following steps describe the procedure for determining the times when these sites were illuminated by SASS (the "hit times"):

1. All SASS measurement orbits were screened for possible intersections within specified off-subtrack distances with surface sites, using a coarse mapping routine from Ref. 9. Orbital parameters and ascending node longitude and time were obtained from Reference 10. This process was done separately for the Northern and Southern Hemispheres since a graphical polar plot is used for mapping. This step yielded a condensed list of orbit segments for each site which were potential hits.
2. For each site location and orbit of this condensed list, finer resolution maps of the SASS footprint swath were generated to determine on which side of the subtrack SASS antennas were making the measurements. These directions were compared with the SASS mode switching schedules (Ref. 11) to cull orbits where the satellite swath was in the wrong direction from the surface site.
3. The time period of intercept of the SASS swath with the surface measurement site was determined. Initially, this was done by generating a viewing schedule (STPTRK subroutine of Ref. 9) for each site and orbit. However, since this program required several iterations at higher resolution for each hit, it

proved to be very time consuming; also the maximum resolution of the hit time was about 36 seconds.

To save time and achieve finer resolution, the procedure to find the time of intercept was modified as follows:

- a. A Mercator plot of the region in which one or more surface truth sites are located was generated using the subroutine of Ref. 9 labeled GNDTRK, and orbital data from Ref. 10. Figure 3 shows such a plot for the Gulf of Alaska region. The two circles around each site are the locus of satellite position required to intercept the site at the side swath (larger circle) and nadir swath (small circle). Segments for all orbits which intercept these sites are shown on this plot also, using the MPASS subroutine of Ref. 9.
- b. To determine the orbital time of intercept, one north-bound and one south-bound orbit segment from figure 3 is transferred to an overlay (Figure 4). Then, the geocentric satellite latitude is related to time past ascending node (Appendix A), converted to geodetic latitude (Appendix B), and transferred to the orbit segments on this figure (Appendix C). When the orbit segments of Figure 4 are aligned with those of Figure 3, the times past ascending node can be determined. Figure 5 shows this alignment for orbit 289. The hit time is taken as the mean of the time the orbit locus intersects the circle around the sites; this is summed with the ascending node time. This method takes much less time than the earlier one. (Several sites and multiple orbits can be handled with one plot). Also, the precision is improved to approximately ± 6 seconds, which is about 6 times better than the earlier method.

Typical Example - Hit Time Determination

In this section, the hit time of ocean data buoys B13 and B19 for orbit 289 are calculated. For this case, the overlay (Figure 4) is superimposed upon the Battelle surface truth site map so that the overlay orbit segment coincides with the one on the map (see Fig. 5). Inspection of this figure shows that the satellite illuminates B19 from 30.3 to 33.9 minutes (after the ascending node). The hit time is recorded as the ascending node time (05:15:37, Ref. 10), plus $\frac{(30.3 + 33.9)}{2}$ or 32.1 min, for a GMT of 05:47:43. The same procedure yields a hit time of 05:50:22 GMT for B13. Note that the orbital pass is a nadir hit for both sites and the required looking direction is right. The hits are therefore identified as N-R (nadir-right) in Table II.

Use of the Hit Table

The user enters the tables by GMT time or orbit number. For a given time segment (column 2) or orbit (column 3), the table lists all sites illuminated by SASS (column 4), the viewing direction relative to the subtrack (column 5), the ascending node time for the given orbit (column 6), and the time past the ascending node for the particular site.

The direction is given as right or left for the side SASS swath sites within 1150 km of the subtrack. Nadir hits within 140 km of the subtrack are additionally designated with N.

Appendix A

Determination of Geocentric Latitude α as a function
of Time after Ascending Node.

$$\delta = \sin^{-1}(\sin \alpha \sin D) \quad \text{A.1.}$$

where

$$\alpha = \frac{180 \times t}{(\text{descending node time} - \text{ascending node time})} \quad \text{A.2.}$$

t = time after ascending node

D = angle between orbital plane and equatorial plane

Appendix B

Geocentric to Geodetic Latitude Conversion

$$\text{lat}_b = \tan^{-1} \left[\frac{\tan (\text{lat}_a)}{(1-f)^2} \right]$$

B.1.

where:

lat_a = geocentric latitude

lat_b = geodetic latitude

$$f = \frac{1}{298.257} = \text{oblateness of the Earth}$$

Appendix C

Mercator Latitude Ticks

The Mercator "projection" modifies the cylindrical projection to allow latitudinal distortion to equal longitudinal distortion. Thus, map distances represented by latitude in Mercator are found by integration:

$$k \int_{\text{lo lat}}^{\text{hi lat}} \sec \theta d\theta = k \left[\ln(\sec \theta + \tan \theta) \right]_{\text{lo lat}}^{\text{hi lat}}$$

C.1.

where θ = latitude

Using this relationship, and k obtained from the dimensions of the graphics Mercator outline of fig. 4, precise latitudes are located on the plot.

16. Abstract					
<p>This publication provides a list of times that the Sea Sat A Satellite Scatterometer (SASS) illuminated from directly above or directly abeam, selected surface sites where in situ winds were measured. The list is ordered by the Greenwich Mean Time (GMT) of the midpoint of the illumination period (hit time) for a given surface site. The list provides the site identification, the orbit number and the direction from the subtrack in which the truth lies.</p> <p>The accuracy of these times depends in part upon the ascending node times, which are estimated to be within ± 1 sec, and on the illumination time relative to the ascending node, which is estimated to be within ± 6 seconds. The uncertainties in the times provided were judged to be sufficiently small to allow efficient and accurate extraction of SASS and in situ data at the selected surface sites. The list contains approximately six thousand hit times from 61 geographically dispersed sites.</p>
