The research described in this publication was carried out by the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration. This work was sponsored by the Program Assurance Division, Office of Chief Engineer, NASA Headquarters, Washington, D.C. 20546.

ABSTRACT

This document is part two of a three-volume set. Volume I provides total ionizing dose radiation test data on diodes, bipolar transistors, field effect transistors, and miscellaneous discrete solid-state devices. Volume II provides similar data on integrated circuits. Volume III provides a detailed analysis of the data from Volumes I and II. Volume III will be released during 1982.

The data presented here are presented in graphic, tabular, or narrative format, depending on the complexity of the integrated circuit. Most of the tests were done using the JPL or Boeing electron accelerator (Dynamitron) that provides a steady-state 2.5-MeV electron beam. However, some radiation exposures were made with a Cobalt-60 gamma ray source. The results obtained with the Cobalt-60 source should be regarded as only an approximate measure of the radiation damage that would be incurred by an equivalent dose of electrons. All data were generated in support of NASA space programs by the JPL Radiation Effects and Testing Group (514).

SECTION I

INTRODUCTION

The data presented in Volume II of this report describe the results of Total Ionizing Dose (TID) tests of integrated circuits (ICs).¹ The data were obtained by the Jet Propulsion Laboratory (JPL), under contract to NASA, in order to assure the "hardness" (radiation resistance) of components to be used in the Jupiter radiation environment. However, the data is applicable to any ionizing (total dose) radiation environment. Two primary radiation sources types were used: Cobalt-60 gamma ray sources and Dynamitron electron accelerators capable of delivering 2.5-MeV electrons at a steady rate. Irradiations of complex ICs were sent to the Boeing Radiation Effects Laboratory (BREL), Seattle, where the necessary computerized test equipment was available. The work at BREL was subject to JPL specifications and procedures.

Some of the data are presented in a graphic format for various operating conditions as a function of dose. A measure of the statistical variations of each device lot is provided by the tabulated standard deviations at the bottom of each graph. The information on some other ICs is presented in tabular format. For more complex large-scale integrated circuit (LSI) type of devices, the data are given in a narrative form, which gives proper emphasis to the radiation-induced changes in the measured parameters. Where there are irradiations of two or more different lots of a given device type, each lot is treated as an entirely separate test.

¹Volume II contains only integrated circuit data. For data on diodes, bipolar transistors, and miscellaneous semiconductor types, refer to Volume I.

All data taken here substantially meet the specifications of MIL-STD-883B, method 1019.1 (August 1977) for environments where short-term annealing is not a relevant problem. Electrical parameter measurements were usually taken within 20 minutes of the completion of each irradiation. Each test consisted of three or more radiation levels at room temperature. The devices under test were maintained at worst-case bias conditions during the radiation exposure.

SECTION II

DOCUMENT USES AND LIMITATIONS

The purpose of this report is to provide a large amount of test data for integrated circuits exposed to a steady-state total ionizing dose irradiation. As such, it offers a useful comparison of the radiation response of different devices that might be considered in the development (circuit design) of a radiation-hardened system. It also offers a quick method for assisting an engineer to determine the weak links in an existing system and an approximation of the radiation tolerance of the system as a whole.

The data presented here cannot be used as a substitute for a comprehensive testing program of the devices actually used in a given system. It will be clear, on inspecting the data herein, that there are large lot-to-lot or wafer-to-wafer variations in the response of samples of a given device type. The difference in response from functionally identical devices fabricated by different manufacturers is even greater. There was no attempt to remove maverick (outlier) devices from the data plots. Thus, some of the data plots may appear anomalous when compared to other plots for that same device type. It should be noted that a given manufacturer may make a minor adjustment in his processing procedures that will result in a major difference in the device's response to radiation.

SECTION III

RADIATION SOURCES AND DOSIMETRY

A. DYNAMITRON

The Dynamitron electron accelerators at JPL and BREL provide a 2.5-MeV electron beam with a range of beam currents of 10^8 to 10^{10} electrons/cm²-sec. All tests described here were irradiated at each fluence level for exposure times between 5 and 45 minutes.

The parts test geometry for the two dynamitron test facilities is essentially the same. The electron beam is brought out of the beam tube into air through a 0.05-mm titanium window, copper and aluminum scattering foils, and 0.9 m of air. Each of these materials scatters the electrons slightly so that the scattered beam has a variation in uniformity of less than 20 percent over the array of parts being tested. The parts test array is confined within a 25-cm diameter circle perpendicular to the direction of the beam. At the center of the circle is the aperture of a vacuum Faraday cup, which is used to measure the flux and fluence of the electron beam. The beam is centered on the Faraday cup with a quadrupole magnet prior to the installation of the test samples. The output from the Faraday cup is a current that is fed into a current integrator, which is calibrated daily against a standard current source. The integrator is set to shut off the electron beam automatically when the desired fluence level is received at the Faraday cup.

B. COBALT-60 SOURCES

The Cobalt-60 gamma ray sources at JPL and BREL were both used. The gamma rays consisted primarily of 1.17 and 1.33 MeV photons with lower energy photons and secondary electrons arising from scattering and absorption. The gamma field was uniform within ± 10 percent in the area where parts were exposed. Thermoluminescent dosimetry (TLD), consisting of lithium

fluoride/Teflon microrods, was used for uniformity checks. Calibration of the source was performed with Landsverk ion chambers of ± 2 percent accuracy, traceable to the National Bureau of Standards. Bimonthly dose rate computations were performed to account for the radioactive decay of the Cobalt-60 source. Exposure times with the Cobalt-60 sources were typically 5 to 20 minutes for each radiation level. Longer times (up to 4 hours) were required for high-dose applications since the maximum uniform dose rate available was 150 Gy/min [15,000 rad(Si)/min] at JPL.

SECTION IV

TEST SETUP AND PROCEDURES

A. GENERAL REMARKS

The test setup and procedures used here were developed in accord with the specifications of MIL-STD-883B (August 1977), method 1019.1. All tests were done at $25^{\circ}\text{C} \pm 3^{\circ}\text{C}$, using low noise power sources and instrumentation subject to periodic calibration. Some tests were performed in situ (without removing the test devices from the radiation area), whereas others required remote testing. In the latter event, a mobile bias fixture was used to maintain bias except during the brief measurement period.

A detailed test plan was written for each test, which included part description, irradiation bias conditions, radiation levels, electrical parameters to be measured, and measurement conditions. The data were processed by hand and by computer, and the calculation of normal standard deviations was made after deletion of clearly erroneous data. Such individual data can be retrieved, if required, by specifying the JPL log number given with each data plot to the Radiation Effects and Testing Group (Section 514) at JPL.

B. IN SITU TESTING

A matrix board switching system was built to be used as a master control and switching panel. It was located outside of the irradiation area for all in situ tests. The board interfaced the devices under test (DUT) to the power supplies and measurement equipment via a special 15-meter (50-foot), double-shielded cable (see Figure 1). A built-in potentiometer for each DUT could be used to control bias voltages and currents. The matrix board was designed with very high insulation resistance so that very low current measurements (10-50 pA) could be made.

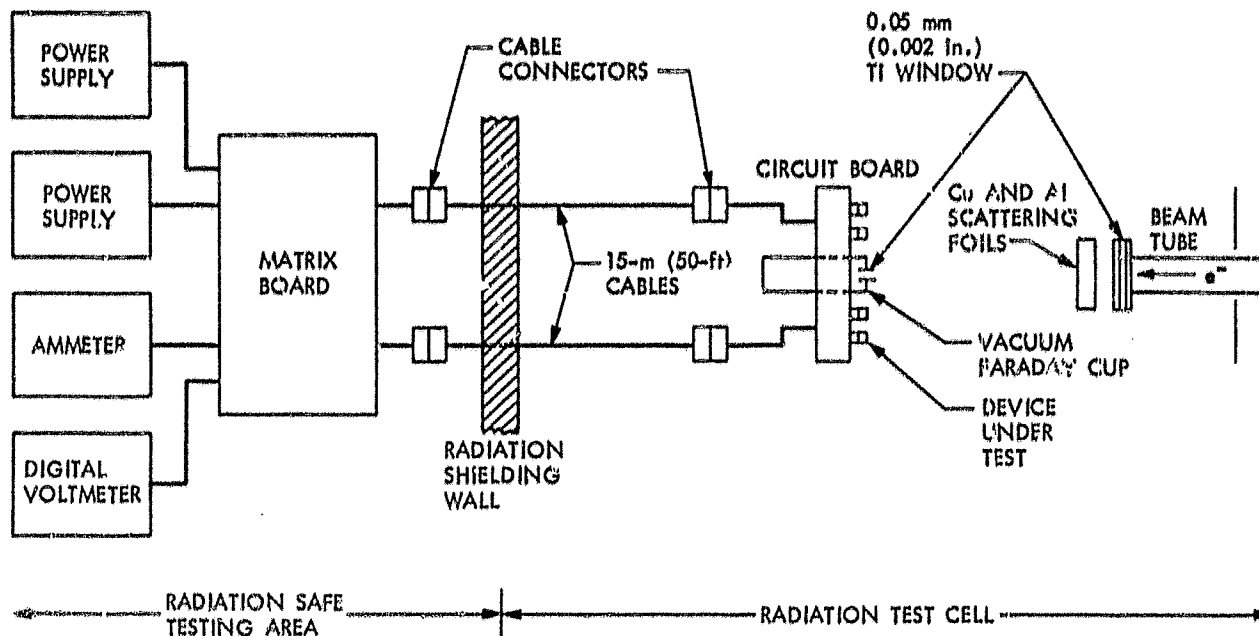

Figure 1. Block Diagram of the Test Setup for in situ Testing With the Electron Accelerator (Dynamitron)

C. NON-IN SITU TESTING

For the remote (non-in situ) tests, the DUTs were removed from the site for approximately 20 minutes between each radiation level. A mobile bias (battery) was applied to the devices at all times except during parameter measurements. Remote measurements were performed using a Tektronix 178/577 curve tracer, a Tektronix 3260 IC tester, or a bench fixture. Occasionally, custom-built test circuits were used to simulate the circuit application of the devices tested.

D. TESTING AT THE BOEING COMPANY

A number of ICs were tested for JPL at the Boeing Radiation Effects Laboratory (BREL). Complex LSI devices--such as A/D converters, memories, and microprocessors--were irradiated with the BREL Dynamitron or Cobalt-60 sources and tested on a Tektronix 3260 computerized IC tester. Most of these tests were non-in situ. The test programs were specified by JPL personnel. The data developed was then sent to JPL for analysis.

SECTION V

DATA PRESENTATION

Some of the data are presented in graphic form and some are summarized in tables. A sample graph, explaining the nomenclature, is shown in Figure 2. Each of the electrical parameter data plots is represented by a single line per graph. Several of the IC parameters are plotted as delta values, which are the radiation-induced changes in a parameter as a function of dose. These include the radiation-induced change in the offset voltage, ΔV_{OS} ; the radiation-induced change in the offset current, ΔI_{OS} ; and the radiation-induced change in the bias current, ΔI_B . Offset values are always taken as positive, regardless of changes in the algebraic sign that may occur during the course of irradiation. Both the positive and negative open-loop gain, $\pm A_{VOL}$, are presented in decibels (dB) versus total dose. The other parameters for the ICs are plotted directly; that is, not using delta values.

A table at the bottom of each graph lists the test conditions when applicable and the normal standard deviations of each data point at each dose level.²

The dose units are in Grays (Gy) where 1 Gray equals 100 rads; for example, 10^{13} 3-MeV electrons/cm² = 250,000 rads(Si) = 2500 Gy(Si).

Date codes usually indicate when the device was packaged. For example, 7920 indicates the device was packaged in the twentieth week of 1979. If no date code is available, the space may be used for other identifying numbers such as wafer number or lot number.

²The log-normal or other types of distributions may provide a better fit for some radiation data than the normal distribution. Hence, caution should be exercised in estimating worst-case conditions based on the limited statistical data presented here.

The word "Fail," shown in some of the tabular data, indicates that the device will not function in its normal mode.

The narrative format is used to describe some of the tests of large-scale ICs (LSIs) because of the complexity of the parameter measurements and resultant difficulty in putting data into a computer for processing into curves.

Figure 2. Description of Graph Format

DEVICE: 1802
TYPE: Microprocessor, Rad-Hard CMOS
MANUFACTURER: Sandia
DATE CODE: 8046, Lot B0442A

DEVICES TESTED: 4
TEST DATE: 3-20-80
SOURCE: 1.25 MeV Gamma
LOG NUMBER: 0709 and 0710

RADIATION BIAS CONDITION: (2 devices) $V_{CC} = 10$ volts
(2 devices) $V_{CC} = 7$ volts

The 10-volt biased devices showed less degradation than the 7-volt biased devices.

A 24-hour annealing test indicated that the parameters had various annealing responses, including some reverse annealing on one device.

The clock-crystal inverter thresholds (V_{TNX} and V_{TPX}) showed significant changes. V_{TPX} is the most sensitive indicator of radiation damage; three of the devices were slightly beyond the preradiation limit at 1500 Gy(Si), and the parts continued to degrade up to 6000 Gy(Si).

The functional test was performed at 1.2 MHz. All devices passed at both 7 and 10 volts up to 3000 Gy(Si). At 6000 Gy(Si), all devices failed the 7-volt functional test, and one device failed the 10-volt functional test.

The overall results indicate that this lot (B0442A) of devices is acceptable for 10-volt operation after an exposure of 2000 Gy(Si), but considerable caution should be used in lower voltage applications in radiation environments.

 $V_{RB} = -2.0$ volts

RESULTS: Worst-Case Parameter Values, $V_{CC} = 5.0$ volts
 $V_{EE} = -6.0$ volts
 $V_{RT} = 0.0$ volt
 $V_{RB} = -1$ volt

ADI	Analog Devices, Inc.
AMD	Advanced Microdevices Corporation
ATC	Applied Technology Corporation
EXR	Exar Integrated Systems
HAR	Harris Corporation, Semiconductor Division
INL	Intersil, Inc.
MNC	Micro Networks Corporation
MOT	Motorola, Inc., Semiconductor Products Division
MPI	Micro Power Systems, Inc.
NSC	National Semiconductor Corporation
PMI	Precision Monolithics, Inc.
RCA	RCA Corporation, Solid State Division
SIL	Siliconix Devices, Inc.
STI	Spectrum Technology, Inc.
TIX	Texas Instruments, Inc.
TRW	TRW, Inc., Semiconductor Division

APPENDIX B

INTEGRATED CIRCUIT ELECTRICAL PARAMETER
SYMBOLS AND ABBREVIATIONS

INTEGRATED CIRCUIT ELECTRICAL PARAMETER
SYMBOLS AND ABBREVIATIONS

AOL ERR	Gain error
AOL OFF	Offset gain
+AV	Positive voltage gain
-AV	Negative voltage gain
+A _{VOL}	Positive voltage gain under load
-A _{VOL}	Negative voltage gain under load
F _{MAX}	Maximum frequency
+FSACC	Positive full-scale accuracy
-FSACC	Negative full-scale accuracy
I _{AMP-IN}	Amplifier input current
I _B	Input bias current
I _{CC}	Power supply current
I _{CC-BLK}	Power supply current (blank mode)
I _{CC-CONV}	Power supply current (convert mode)
I _{CC(H/L)}	Power supply current (high/low level)
I _{DD}	Drain supply current
+I _{DFT}	Positive drift current
-I _{DFT}	Negative drift current
I _{DN}	Output drive current (negative)
I _{DP}	Output drive current (positive)
I _{EE}	Emitter power supply current
I _{EE-BLK}	Emitter power supply current (blank mode)
I _{EE-CONV}	Emitter power supply current (convert mode)
I _{FS}	Full-scale current
I _{I(H/L)}	Input current (high/low level)
I _{LEAKAGE}	Leakage current
I _{LOGIC}	Logic power supply current
IN-OUT JITTER	Input-to-output jitter
I _{O(H/L)}	Output current (high/low level)
I _{OS}	Offset current
I _{OZ(H/L)}	Tri-state output leakage current (high/low level)
I _{RB}	Reference current, bottom

INTEGRATED CIRCUIT ELECTRICAL PARAMETER
SYMBOLS AND ABBREVIATIONS (Continuation 1)

I_{REF}	Reference current
I_{SC}	Output source current
I_{SK}	Output sink current
I_{SS}	Leakage current
I_{SYM}	Current symmetry
I_{ZERO}	Zero-scale current
LSB	Least significant bit
NONLIN	Nonlinearity
OFFERR	Offset error
OFFSET	Offset voltage
PWD_{TH}	Pulse width threshold
Q TRANS	Storage transfer
Q2-JITTER	Output jitter measured at Q2 emitter
ΔR_{AVG}	Change in average resistance
+SR	Slew rate positive
-SR	Slew rate negative
t_{AA}	Address access time
t_{AC}	Access time from chip select
t_{ACQ}	Acquisition time
t_{BLANK}	Blank time
t_{CONV}	Conversion time
t_{DS}	Timing specification
t_{DSC}	Timing specification
$t_{OFF/ON HBE}$	High bit enable propagation delay
$t_{OFF/ON LBE}$	Low bit enable propagation delay
t_{PD}	Propagation delay time
t_{PD-DO}	Propagation delay time from clock input to data output
t_{PDE}	Propagation delay from register enable to output
V_{CC}	Collector voltage
V_{DD}	Drain supply voltage
V_{EE}	Emitter voltage

INTEGRATED CIRCUIT ELECTRICAL PARAMETER
SYMBOLS AND ABBREVIATIONS (Continuation 2)

$V_{I(H/L)}$	Input voltage (high/low level)
V_{LOGIC}	Logic voltage
$V_{O(H/L)}$	Output voltage (high/low level)
V_{OS}	Offset voltage
V_{REF}	Reference voltage
$V_{TH(H/L)}$	Threshold voltage (high/low level)
X-JITTER	Phase jitter
