ABSTRACT

The differential thermal analyzer is a very suitable instrument for the rapid analytical study of the thermal behavior of battery electrodes. Solid samples can be studied in the range of 0°C - 500°C using the standard cell assembly. Thermal behavior of battery electrodes is automatically recorded by the analyzer and it can be used for qualitative analysis. A study is also being made of the behavior of battery electrodes which have been charged at different levels.

INTRODUCTION

Differential thermal analyses are conducted with a DuPont Model 900 DTA unit. DTA is a technique for studying the thermal behavior of materials as they undergo physical and chemical changes during heating and cooling. Two 4mm-diameter tubes, one containing sample and the other containing a reference material, such as glass beads, are heated at a uniform rate in a heating block. The temperature differential between the two tubes will remain zero as they are heated unless the sample undergoes an endothermic or exothermic reaction. A thermocouple is inserted in the tube containing the sample and another thermocouple is inserted in the tube containing the glass beads. The glass beads do not undergo any chemical change in the temperature range under study. As long as the temperature of the sample equals the temperature of reference material, the two thermocouples produce identical voltage and the net voltage differential is zero. When an exothermic or an endothermic change takes place in the sample, the sample temperature no longer equals the reference temperature and the resultant voltage differential reflects the difference in temperature and either a positive or negative ΔT peak on the graph results. The DTA unit plots the temperature of the heating block on the X-axis; on the Y-axis it plots the difference in temperature between the sample and the reference, ΔT . An exotherm is plotted as a rise from the base line; an endotherm as a decrease from the base line.

DISCUSSION OF THE RESULTS

Several positive and negative battery electrodes were analyzed. The negative plates show a first endotherm between 245°C - 250°C. This is a very large peak. The second endotherm occurs at 300°C which is indicative of the decomposition of $\text{Cd}(\text{OH})_2$ (see graphs 1 to 6). In the analysis of positive plates, a first weak endotherm occurs at 100°C, which indicates loss of H_2O from $\text{Ni}(\text{OH})_2(\text{H}_2\text{O})_n$ molecules. A second, large, endotherm occurs in the range of 290°C - 300°C, which is indicative of the decomposition of $\text{Ni}(\text{OH})_2$ to NiO and H_2O (see graphs 7 to 17).

ABSTRACT

Atomic Absorption Spectroscopy is used to determine nickel, cobalt, cadmium, and potassium content in battery electrolytes and electrodes. We are also determining the interference effects of one element in the presence of others. Atomic Absorption is a quick and accurate method for the determination of traces of the above mentioned metals.

Introduction

Sealed Ni-Cd cells have proved to be a useful and reliable re-chargable source of power for aerospace applications. However, it has been found that sometimes these cells have failed.

Although it is not completely known what leads to such failures, it has been found experimentally that some of the factors which contribute to the final failure of the batteries are :

1. Extent and nature of cycle regime
2. Operating temperature
3. Carbonate contamination
4. Cd migration
5. Nature and condition of separator

The analysis of negative electrodes, positive electrodes, and of the electrolyte is also important.

A.A spectroscopy is being used to analyze the elements of interest (Ni, Cd, Co, and K) in the electrodes and electrolytes of the Ni-Cd cells.

These results have been compared with those obtained by standard chemical analysis method and are in agreement. A.A spectroscopy is much quicker and embraces virtually all alloying components contained in Ni-Cd cells.

This method is being used to analyze for concentration of trace metals in negative and positive electrodes of batteries. This should prove useful in determining the amount and effects of these trace metals in functioning and durability of Ni - Cd cells.

Instrumentation

A Perkin-Elmer Model 403 Atomic Absorption Spectrophotometer was used. This unit has a digital read-out panel. High intensity cathode tubes for Ni, Cd, and Co. were used depending on which element was being measured. Operating conditions were generally those recommended in the Analytical Methods Book.

The steps listed below were followed in adjusting the Model 403 Spectrophotometer in preparation for performing the analysis.

1. The instrument and exhaust hood are turned on and allowed warm-up at the specified current given in the Analytical Method Book for two hours or until stability is achieved. Stability is achieved when no zero shift is apparent over a five minute interval.
2. The air supply is turned on and the air pressure is set at 62 lbs/sq. in.
3. The acetylene supply is turned on and acetylene pressure is set at 27 lbs./sq. in.
4. The burner is ignited.
5. The flame should be blue and transparent with an oxidizing region about 4 mm.
6. The slit control is set at the value given in the Analytical Methods Book for the respective elements.
7. The adjustment of the atomizer is made by turning the capillary outward until "blow-back" occurs, then, turning inward until absorption is maximized. Standard solutions are aspirated through a tube into the flame for not less than 15 seconds.

OF POOR QUALITY

Known Solutions Preparation

The solutions used were prepared from standard solutions of 1000 (Parts per Million (PPM)). The dilutions were made as follows:

10 ml of 1000 PPM standard solutions were diluted to a final volume of 500 ml with deionized water to give a solution of 20 PPM concentration. This 20 PPM solution was used as a stock solution. Further dilutions were made as follows:

1. 5 ml of 20 PPM solution was diluted with deionized water to give a final volume of 100 ml and a solution of 1 PPM.
2. 10 ml of 20 PPM solution was diluted to a final volume of 100 ml and a solution of 2 PPM.
3. Repeat the above procedure with 15 ml of stock solution to get 3 PPM solution.
4. Repeat above procedure with 20 ml stock solution to yield a solution of 4 PPM.
5. Repeat above procedure with 25 ml of stock solution to get a solution of 5 PPM.
6. Repeat above procedure with 30 ml of stock solution to get a solution of 6 PPM.
7. Repeat above procedure with 35 ml of stock solution to get a solution of 7 PPM.
8. Repeat above procedure with 40 ml of stock solution to get a solution of 8 PPM.
9. Repeat above procedure with 45 ml of stock solution to get a solution of 9 PPM.
10. 50 ml of stock solution are diluted with 50 ml deionized water to get a final solution of 10 PPM.

Drawing of Calibration Curve

The Atomic Absorption Spectrophotometer readings are displayed in absorption but they can be readily converted by means of a table to percent absorption which varies almost linearly with concentration. The conversion table is provided in the Analytical Methods Book for Perkins-Elmer Model 403 A.A. spectrophotometer.

The instrument parameters are recorded with each set of data so they can be duplicated when corresponding sample runs are made. Each curve standard is run in ascending order of element concentration. Curves can be conveniently plotted on expanded logarithmic paper

Analysis of Samples

The agreement of the results obtained by A.A Spectroscopic analysis with those obtained by standard analysis have previously been confirmed (Please see annual report 1979).

For analysis of each sample a calibration curve is derived from standard solutions. The given samples are diluted and the concentration of the metal in the aliquot is calculated from the calibration curve. This is multiplied by the dilution factor to give the concentration of the metal in the original sample.

The results obtained are given in table Ia through table XXb. Tables "a" contain the data for standard calibration curve and tables "b" contain the data for analyzed samples.

The points corresponding to each analyzed sample have been marked on the calibration curve.
