ABSTRACT

An atlas of N₂O lines between 800 and 5200 cm⁻¹ obtained from low-pressure, long-path-length samples at 296K is presented. Many of the line centers are marked and their positions are tabulated. The peak absorptances of the weaker lines in the atlas are similar to those expected in an extreme path through the atmosphere.

INTRODUCTION

More than 30 infrared absorbing gases are either known or are suspected to exist in the atmosphere (1). Their mixing ratios vary from 1-2% for the case of H_2O near ground level to less than 1ppb for many of the trace constituents. Estimates of these mixing ratios can be obtained by analyzing spectra of atmospheric paths. However, the strongest features of many of these trace constituents occur in regions where there are bands of other gases, especially the more abundant constituents. Thus an unambiguous determination of the amounts of the trace gases requires a detailed knowledge of the spectra of the more abundant constituents.

N_2O has a mixing ratio of about 0.3 ppm in the lower atmosphere and its stronger bands can be seen in atmospheric spectra of a few hundred meters, other weaker bands appear in spectra of longer path lengths.

Information about many of the lines in these bands is given in the AFGL listing of the line parameters of atmospheric gases (2). This tabulation can be used to generate synthetic spectra of N_2O for wide ranges of path lengths and pressures. A number of spectra of laboratory samples of N_2O have also been published. These usually cover small spectral regions and the sample conditions are usually not specified. No experimental spectra covering wide spectral regions for the same sample are available. Such atlases could be used to design experiments to search for weak features of other atmospheric gases since they show, not only the positions of bands of N_2O and their relative intensities, but also N_2O absorption-free regions.

This atlas contains spectra of long path lengths of low pressure samples of N_2O and most of the lines of N_2O which are significant features of atmospheric spectra can be seen.

(1)

DESCRIPTION OF THE ATLAS

1. Instrumentation.

The N_2O samples were contained in a 10m base path, multiple-traversal cell (3) and the spectra were collected with a Nicolet Fourier Transform Spectrometer (FTS) having a nominal resolution of about 0.05 cm^{-1} . Portions of two spectra are shown. The spectrum from 800 to 2700 cm^{-1} is that of a 0.5 torr sample of N_2O at 296K in a path of 300 m. It was collected with a HgCdTe detector whose detectivity is low at high frequencies. A second spectrum, covering the region from 2400 to 5200 cm^{-1} , is also included. The sample, in this case, was 1 torr N_2O at 296K in a path length of 476 m. An InSb detector was used. The overlap between these spectra allows the band intensities in both spectra to be compared. The HgCdTe spectrum is identified with the label "FREQ CM^{-1} " on the abscissa, the InSb spectrum is labelled "INS".

2. Preparation of the Atlas.

The interferograms were apodized by a cosine apodization function before transformation into spectra. Since the N_2O line widths are much smaller than the spectral resolution, there are relatively few data points in the vicinity of each line. The visual appearances of the spectra were therefore improved by smoothing and adding additional calculated points by quartic splines interpolation.

During this process the positions of many of the absorption minima were estimated. These positions are shown above the spectra and are also tabulated on the page facing each spectrum. In some regions more than 120 lines were located in a 20 cm^{-1} interval and these regions have been subdivided to allow all the line positions to be tabulated. Since many of the smaller minima are due to noise, the program included a criterion to reject minima below a given threshold value. This caused some features, which are probably real, to be rejected. It is estimated that more than 6000 lines have been located with an accuracy of about 0.005 cm^{-1} . Some of these lines are due to H_2O and CO_2 in the portion of the optical path which could not be evacuated.

3. Comparison with Atmospheric Spectra.

The pressures of the N_2O samples were much less than the pressures in the lower atmosphere where most of the N_2O occurs. Thus the appearances of the lines in the atlas differ from those observed in atmospheric spectra.

At pressures of about 1 torr the widths of the N_2O lines are

primarily due to Doppler broadening and have values given by

$$\alpha_D = (v/c)(2kT \ln 2/m)^{1/2} \quad (1)$$

For N_2O , at 296K, the Doppler width varies from about $1.1 \times 10^{-3} \text{ cm}^{-1}$ at 1000 cm^{-1} to $5.5 \times 10^{-3} \text{ cm}^{-1}$ at 5000 cm^{-1} . These values may be compared with the typical line width due to collision broadening of about 0.09 cm^{-1} at 296K and 760 torr and $6 \times 10^{-5} \text{ cm}^{-1}$ at 296K and 0.5 torr pressure.

At very low pressures the dependence of the equivalent widths of the N_2O lines on path length is different from that usually encountered in the atmosphere. As the path length increases the stronger lines rapidly saturate and their equivalent widths become nearly independent of path length, at the same time, the equivalent widths of weaker lines increase so that they become visible, until they, in turn, also reach saturation. The spectral region where there is significant absorption by an individual line is much smaller than the spectral resolution of the FTS. Thus the appearance of the lines in the atlas is dominated by the instrument and it is difficult to infer the relative intensities of the lines. However, such spectra allow both very weak and very strong lines to be shown simultaneously.

It is also possible to compare the appearance of the weaker N_2O lines in the atlas with their expected appearance in an atmospheric spectrum.

McClatchey et al (4) have established an intensity criterion for deciding whether a given line will be included in the AFGL line parameter listing. The minimum intensity S_{\min} for inclusion requires that the line will have a 10% peak absorptance in an extreme atmospheric path. This extreme path is space-to-space, tangent to the earth's surface. For N_2O , S_{\min} is $3 \times 10^{-23} \text{ cm}^{-1}/\text{molecule}$ (4), and is based on the atmospheric N_2O mixing ratio, its variation with height, and the method of calculating the extreme path. We have confirmed this value by assuming a constant N_2O mixing ratio of 0.28 ppm, an extreme path with no refraction, and by the following approximate calculation.

The pressure P_h at height h in the atmosphere

$$P_h = N_h mg,$$

when N_h is the number of air molecules per unit area above h , and m is the mean molecular mass.

For standard atmospheric pressure

$$N_0 = P_0 / mg,$$

where

$$P_0 = 1.013 \times 10^5 \text{ N/m}^2,$$

$$m = 29 \text{ a.m.u.}$$

$$= 4.81 \times 10^{-26} \text{ kg},$$

and

$$g = 9.8 \text{ m/sec}^2$$

$$\text{Thus } N_0 = 2.14 \times 10^{29} \text{ mols/m}^2$$

The height of a homogeneous isothermal (273K) air column with a density equal to that of an ideal gas at STP ($L = 2.69 \times 10^{25} \text{ mols/m}^3$) which produces a pressure P_0 is

$$H = P_0 / L \cdot mg$$

$$= N_0 / L$$

$$\approx 8 \text{ km.}$$

H is the equivalent height of the atmosphere and N_0 is the number of molecules/(m^2 -airmass). The number of air masses in the extreme path ($2x$) through the atmosphere is obtained from the triangle OAB of Fig. 1.

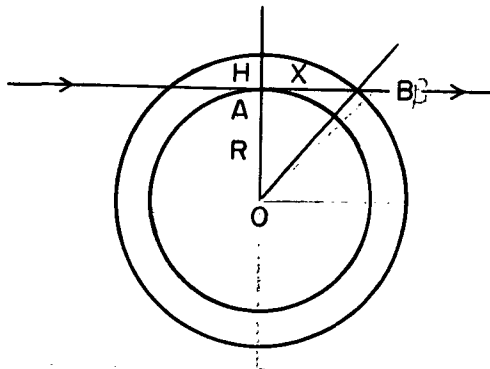

Figure 1. Geometry of extreme atmospheric path. The atmosphere is assumed homogeneous with a depth $H = 8 \text{ km}$ and the mean radius of the earth $R = 6378 \text{ km}$. The extreme path in this approximation is $2x$.

$$x^2 + R^2 = (R+H)^2$$

Since $h \ll R$

$$x^2 \approx 2HR$$

and

$$x \approx 319 \text{ km.}$$

The number of air masses in the extreme path

$$n = 2x/H,$$

$$\approx 80.$$

For an N_2O mixing ratio of $p = 0.28$ ppm the number of N_2O molecules/cm² along the extreme path

$$\begin{aligned} N_{\max} &= nN_0 p \\ &= 4.8 \times 10^{20} \text{ mol/cm}^2 \end{aligned}$$

In order to calculate the absorptance by an N_2O line in this extreme path it is assumed that the lines have a Lorentzian shape with an absorption coefficient

$$k(\nu) = (S\alpha/\pi) [(\nu-\nu_0)^2 + \alpha^2]^{-1},$$

when S is the line intensity and α is the collision broadened width. If \bar{P} is the effective atmospheric pressure along this path

$$\alpha = \bar{P} \bar{\alpha}_0 / P_0,$$

where $\bar{\alpha}_0 \approx 0.09 \text{ cm}^{-1}$ at m^{-1} is the mean width of N_2O lines at one atmosphere and \bar{P} is taken to be $0.75 P_0$.

The transmittance at line center is

$$T(\nu_0) = \exp - [SN_{\max}/\pi\alpha],$$

and

$$S = \pi\alpha \ln T(\nu_0) / N_{\max}.$$

The intensity required to give a line with $T(\nu_0) = 0.9$ in an extreme path is then found to be $4.6 \times 10^{-23} \text{ cm}^{-1} (\text{mol/cm}^2)^{-1}$ which is close to the value of $3 \times 10^{-23} \text{ cm}^{-1} (\text{mol/cm}^2)^{-1}$ quoted in (4).

The widths of these lines, $\alpha \sim 0.07 \text{ cm}^{-1}$, are larger than the spectral resolution 0.05 cm^{-1} of the FTS used in this investigation. Thus if the same instrument was used to observe N_2O lines in this extreme path the peak absorptance of a line with intensity S_{\min} would be nearly 10%. If it is assumed that such lines are in the \min linear region of the curve of growth the equivalent width

$$W \approx S_{\min} N_{\max} \\ = 2.2 \times 10^{-2} \text{ cm}^{-1}.$$

These results may be compared with the appearance of N_2O lines in the atlas. The spectrum from 800 to 2700 cm^{-1} is of a sample of 0.5 torr N_2O in a 300 m path at 296K containing $4.9 \times 10^{20} \text{ N}_2\text{O} \text{ mols/cm}^2$. This is almost the same as the number in the extreme atmospheric path. The sample whose spectrum is shown from 2400 to 5200 cm^{-1} contained $1.6 \times 10^{21} \text{ mols/cm}^2$.

Estimates of the equivalent widths of the N_2O lines in the atlas can be obtained from the tables of the equivalent widths W of Voigt shaped lines given by Jansson and Korb(5). These authors have tabulated the dependence of W/α_D on the quantities $P^2 X$ and a where

$$P^2 = (S/\alpha_D) [(\ln 2)/\pi]^{1/2},$$

$$\text{and } a = (\alpha_L/\alpha_D)(\ln 2)^{1/2},$$

and x is the amount of absorber in the path.

It is found that the equivalent width of an N_2O line with intensity S_{\min} at 1000 cm^{-1} in the spectrum of the 300m path, 0.5 torr N_2O sample is $5.3 \times 10^{-3} \text{ cm}^{-1}$ and the equivalent width of a line with the same intensity at 4000 cm^{-1} in the 476m path, 1 torr N_2O sample is 0.017 cm^{-1} .

The equivalent widths of these laboratory lines are smaller than corresponding lines in atmospheric spectra since the laboratory lines are not in the linear region of the curve of growth. Estimates of the observed peak absorptances of these laboratory lines can be made by assuming the instrument spectral response function is triangular with a half width $R = 0.05 \text{ cm}^{-1}$. The peak absorptance P of a narrow line of equivalent width W is

$$P \approx 100W/R (\%).$$

It is found that the peak absorptance of a line with S_{\min} at 1000 cm^{-1} is about 11% and for a line with S_{\min} at 4000 cm^{-1} the observed peak absorptance in the atlas is about 34%.

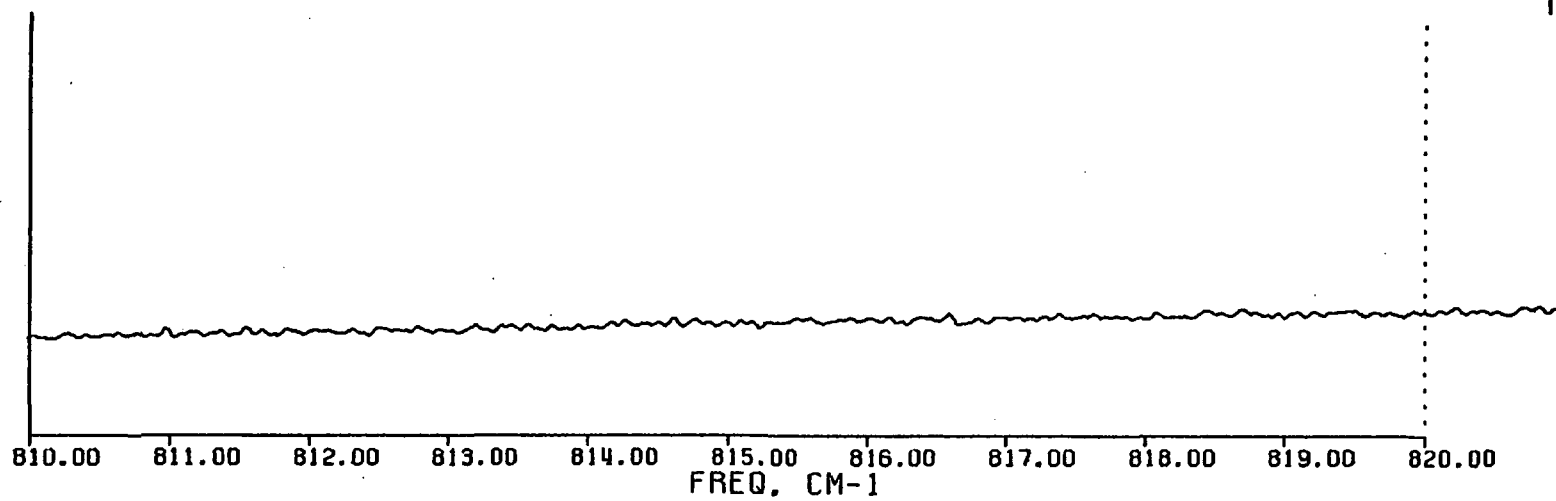

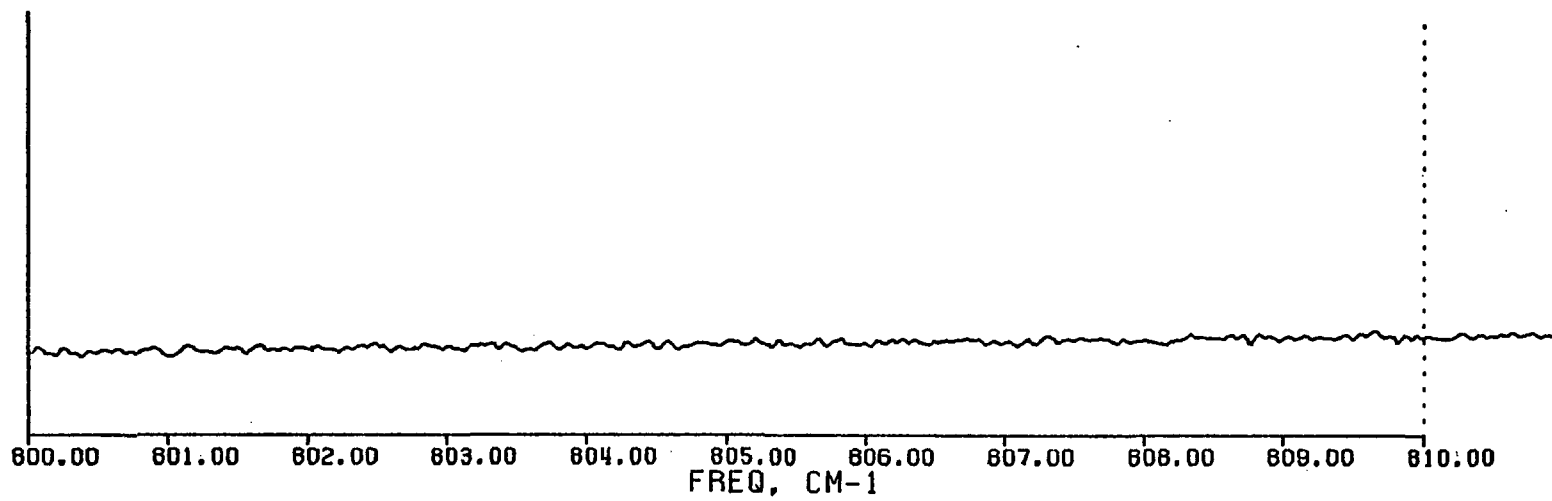

Thus, within the approximations used in these calculations, it is found that the peak absorptances of the weaker N_2O lines in this atlas are similar to those of the weaker lines in the extreme atmospheric path.
