FOREWORD

The study described herein was performed under NASA Contract NAS-3-20578 by the Pratt & Whitney Aircraft Group, Commercial Products Division, United Technologies Corporation, under the direction of Mr. N. T. Monsarrat, Program Manager. The NASA Project Manager was Mr. R. S. Ruggeri, NASA-Lewis Research Center, Fluid System Components Division, Fan and Compressor Branch. The work was performed during the period 20 October 1976 through 30 June 1979. The authors wish to acknowledge the participation and contributions in the fulfillment of this contract by Messrs. W. T. Hanley and H. A. Harmon of the Pratt & Whitney Aircraft Group and by Mr. C. L. Crockett of the United Technologies Research Center, Test Facilities Operations Group.

Pratt & Whitney Aircraft Group

SUMMARY

Tests were conducted on two three-stage compressors, designed with aspect ratios of 0.81 and 1.22, to acquire detailed overall aerodynamic performance data on the effects of aspect ratio in high hub-tip ratio stages, similar to those at the rear of advanced multistage compressors. Both compressors were designed for 15 percent surge margin. The 0.81 aspect ratio compressor (3S1) was designed for a higher pressure ratio than the 1.22 aspect ratio compressor (3S2) in recognition of the increased capability believed to exist at lower aspect ratios.

The test results showed that the 0.81 aspect ratio compressor exceeded its design surge margin by nine percent despite its higher design loading and demonstrated a peak adiabatic efficiency of 86.1 percent. The 1.22 aspect ratio compressor achieved a higher peak efficiency level (87.0 percent) than the 0.81 aspect ratio compressor, but fell short of its surge margin goal by three percent. The lower aspect ratio compressor exhibited greater efficiency in the endwall regions and a depressed efficiency in the midspan regions. The first stage of the lower aspect ratio compressor exhibited a stalled static pressure characteristic while all three stages of the higher aspect ratio compressor stalled uniformly but below their peak design level.

INTRODUCTION

Compressors for advanced aircraft turbofan engines must combine high efficiency with adequate stability margin in a compact, light-weight configuration. Pratt & Whitney Aircraft experience (ref. 1) with single and multistage compressors suggests that low aspect ratio airfoils have the potential to meet these requirements by combining high loading capability with previously developed low endwall loss technology. A test program was devised to determine the benefits of low aspect ratio in the high hub-tip ratio rear stage environment of an advanced multistage compressor. The aerodynamic configuration chosen for testing was based on the last three stages of the eight-stage, Advanced Multistage Axial Flow Compressor (AMAC) studied under a previous contract (ref. 2). A low Mach number three-stage rig was selected as the test vehicle.

This report presents the results of both the 0.81 aspect ratio (3S1) compressor and the 1.22 aspect ratio (3S2) compressor tests. Details of the design of each of these compressors are presented in ref. 3.

APPARATUS

AERODYNAMIC DESIGN

Two three-stage compressors, designated 3S1 and 3S2, were designed to demonstrate improved blading for the rear stages of highly loaded, advanced core compressors. A schematic of the 3S1 and 3S2 compressors is shown in Figure 1. The average aspect ratio of the 3S1 configuration was 0.81, the overall pressure ratio at design speed was 1.35, and the average diffusion factor (D Factor) was 0.529. The 3S2 configuration was similar to 3S1, but was designed for a fifty percent higher aspect ratio (1.22). The principal aerodynamic design parameters of the 3S1 and 3S2 compressors are given in Table I. The design mean wheel speed, tip diameter, and flow capacity were established to be compatible with the limitations of an existing test facility.

TABLE I

PRINCIPAL AERODYNAMIC DESIGN PARAMETERS

	3S1	3S2
Inlet Corrected Flow; kg/sec (lbm/sec)	4.30 (9.47)	4.30 (9.47)
Corrected Mean Wheel Speed, 50 percent Span; m/sec (ft/sec)	167 (547)	167 (547)
Pressure Ratio	1.357	1.324
Overall Adiabatic Efficiency, %	88.30	88.70
Aspect Ratio, Average	0.81	1.22
Solidity, Average	1.10	1.10
Inlet Hub-Tip Ratio	0.915	0.915
Exit Hub-Tip Ratio	0.915	0.915
Work Coefficient -E-, Average	0.702	0.644
Flow Coefficient - Cx/U, Average (50 percent Span)	0.440	0.444
D Factor, Average*	0.529	0.491
P/(Po-P), Average	0.497	0.467
Tip Clearance, Average cm (in.)	0.033 (0.013)	0.033 (0.013)
Reaction	0.517	0.517

*D Factor Average = Sum of mass average diffusion factors from streamline analysis for the various blade rows divided by the number of blade rows.

The aerodynamic design (see ref. 3) was performed in three steps. First, the analytical design system was adjusted to ensure performance agreement with data from tests of three-stage compressors similar to the 3S1 configuration. Next a preliminary design based on a meanline approach provided a rough flowpath and average aerodynamic quantities. Finally a detailed full-span design, which utilized a streamline calculation procedure, was used to set blading geometry and finalize flowpath dimensions. Circular arc mean camber line airfoils with a 65 series thickness distribution were chosen for all rows because of their excellent low Mach number performance characteristics.

MECHANICAL DESIGN

Compressor Rig

The basic mechanical design of the 3S1 and 3S2 compressor rigs (see ref. 3) consisted of an assembly of interlocking aluminum rings, which formed the compressor case, and a set of aluminum wheels, which were keyed to a central shaft and formed the compressor hub. The 3S1 compressor assembly is shown as the top half of the schematic in Figure 1 and 3S2 as the lower half. A rotating drum design consisting of a rotor assembly supported by bearings at the front and rear of the compressor was used for the inner portion of the rig. The rotor assembly consisted of a stack of aluminum rotor blade carrier and spacer wheels keyed to a central shaft threaded at both ends. The stator assembly consisted of a stack of interlocking stator vane carrier and spacer rings. The parts were secured in place by steel endplates clamped together by tie rods.

All blading was cast using an aluminum alloy material, A356-T6. Blading attachment was accomplished by means of a bolt, which secured the blade or vane to the blade or vane carrier. Typical rotor and cantilevered stator assemblies are shown in Figures 2 and 3, respectively.

Test Facility

The compressor test facility, located at the United Technologies Research Center, consists of the compressor drive system, the inlet and discharge flow ducting, and the data acquisition system. The drive system and compressor are located within a test cell. The operating controls, monitoring instrumentation, and data acquisition system are located in a separate control room.

The major components of the compressor drive system are a DC electric motor and a speed-increasing gearbox. An automatic speed control is utilized to maintain speed at a preset value.

Filtered ambient air is ducted into the test cell and through a plenum that provides uniform pressure and temperature distributions at the compressor inlet. A throttle downstream of the compressor controls the rate of airflow through the compressor. The flow is exhausted through a duct containing a silencer to reduce noise levels before discharging to the atmosphere. The facility is shown schematically in Figure 4.

The Computerized Precision Acquisition Sequencing System (COMPASS) is used for control, acquisition, and recording of the experimental data. Utilizing a minicomputer for control of the data acquisition sequences, COMPASS can acquire parameters that include identification information and calibration data, as well as analog and digital transducer data. The system is self calibrating via primary and secondary pressure and voltage standards and is capable of a pressure measurement accuracy of ±0.10 percent of full scale reading and a temperature measurement accuracy of ±0.14°C (±0.25°F).

INSTRUMENTATION AND CALIBRATION

Compressor Performance Instrumentation

Rig instrumentation was selected to obtain overall compressor performance. Wall static pressures were incorporated to evaluate individual rotor as well as individual stage characteristics relative to design values. Figure 5 shows the locations of the overall performance instrumentation as well as the location of the inter-blade row static pressure taps.

Compressor airflow was calculated from measured total and static pressures in an axial plane close to the bellmouth exit defined in Figure 1 as station 0. Total temperatures used in the calculation were obtained from probes at the compressor inlet instrumentation plane, station 1 (Figure 5). Prior to the rig test program, a detailed flow calibration was performed in which radial traverses in four circumferential locations were made at several flow rates. The data were integrated to establish the true flow at the rig inlet flow measuring plane. The true flow was then correlated with the flow calculated from the midspan instrumentation used during the tests and the correlation was used to establish a flow coefficient which was applied to all data, resulting in an accuracy within one percent of the true flow.

Compressor rotor speed was measured by means of a magnetic pickup. A tachometer converted the pulse rate from the pickup into rotor speed in rpm. Accuracy was within 0.1 percent.

Pressures from pole rakes in the inlet and discharge and from static pressure taps were sensed by gage type analog pressure transducers mounted in multiport scanning valves. These pneumatic switches were also used to apply known pressures produced by the calibration hardware to the appropriate pressure transducers. The accuracy of the pressure measurement system was 0.1 percent of full-scale reading.

All temperatures were measured by Chromel-Alumel Type K thermocouples. Each thermocouple wire was individually calibrated to establish its unique properties relative to the 1968 International Temperature Scale. The temperature measurement system is accurate to $\pm 0.14^{o}C$ ($\pm 0.25^{o}F$).

Compressor inlet and exit total pressure and temperature radial rakes consisted of both five and four element probes. Thus, pressures and temperatures were sampled at nine radial locations. Typical pressure and temperature rakes are shown in Figures 6 and 7. The location, number, and type of performance instrumentation used are given in Table II.

*This instrumentation was located circumferentially to access a discharge stator wake and vane gap.

Rig Safety Instrumentation

Instrumentation was incorporated to monitor rig and drive motor vibrations, bearing temperatures, rotor/case rub, vane/drum rub, and compressor surge.

PROCEDURES

TEST PROCEDURE

The test program consisted of a shakedown run, the performance program, a program to measure running tip clearance, and a data validity check to identify possible performance deterioration during the test program.

Shakedown tests were conducted to substantiate the mechanical integrity of the rig and to verify that the instrumentation hookup and the data acquisition and reduction systems were functioning properly.

The performance program consisted of obtaining six sets of speedlines at each of three separate speeds: 85, 100, and 105 percent of design speed. This procedure ensured statistically accurate average speedlines. In addition, surge points were obtained for each speed.

Dynamic rotor tip clearances were calculated from measurements of the long blade clearances at 18, 85, 100, and 105 percent rotor speed. Measurements were recorded for each rotor at six circumferential locations.

The data validity program consisted of six sets of speedlines at 100 percent of design speed to verify that overall compressor performance had not deteriorated during the test program.

DATA REDUCTION TECHNIQUES

Data reduction programs developed at Pratt & Whitney Aircraft were used to process the overall performance, stage performance, rotor performance, and radial profiles for the two compressors. Raw data from the test stand were recorded in millivolts on magnetic tape for subsequent processing. Preliminary processing converted the millivolt data into engineering units, applied wire calibrations to thermocouple readings, applied Mach number calibrations to pressure and temperature measurements, performed circumferential mass averaging, corrected the data to standard inlet conditions, calculated overall performance, and punched cards.

The punched cards produced by the data reduction program were used in two data analysis programs. The first program modified flow and performance measurements by correcting for probe and inlet losses. This program provided corrected performance cards which were fed into a performance plotting and averaging program. Overall performance for each compressor was based upon the arithmetic average of six repeat speedlines each at 85, 100, and 105 percent of design speed. Spanwise profiles for each compressor were taken from the speedline closest in performance to the average. The second data analysis program calculated stage and rotor static pressure characteristics. The flow of information from test stand through analysis is shown in Figure 8. Details of the data correction and performance calculations are given in Appendix B.

RESULTS AND DISCUSSION

Overall performance, stage and rotor static pressure characteristics; and profiles of inlet and discharge spanwise pressure, temperature and efficiency are presented in this section. The 3S1 and 3S2 compressor test results are compared with each other and with design goals.

OVERALL PERFORMANCE

Overall Performance of 3S1 Compared With 3S2

The overall performance (pressure ratio and efficiency as functions of flow) for both the 3S1 and 3S2 compressors are compared in Figure 9. The characteristics shown for each compressor are averages of six repeat speedlines.

The 3S1 (0.81 aspect ratio) compressor had a one percent lower peak efficiency than the 3S2 configuration, but a greater peak pressure rise and a greater flow range and, as a consequence, a twelve percent higher surge margin. The lower aspect ratio compressor achieved a design speed peak overall adiabatic efficiency of 86.1 percent at a flow of 4.36 kg/sec (9.62 lbm/sec) and a pressure ratio of 1.346. The 1.22 aspect ratio compressor, 3S2, attained a design speed peak overall adiabatic efficiency of 87.0 percent at a flow of 4.35 kg/sec (9.58 lbm/sec) and a pressure ratio of 1.314. Overall performance at design speed is summarized in Table III for each compressor at design speed.

The efficiency of both compressors decreased when speed was increased, but the decrease was greater for the lower aspect ratio compressor. The peak efficiency of 3S1 dropped 0.9 percentage points between 85 percent and 105 percent of design speed. The 3S2 efficiency drop was 0.35 percentage points when speed was increased over the same range. Surge margin to peak efficiency was 24 percent for 3S1 and 12.4 percent for 3S2 at the design speed. Surge margin to the peak efficiency point increased as speed was increased for both compressors. The surge margin of 3S1 was 20.5 percent at 85 percent speed and 27.7 percent at 105 percent speed. Surge margin of 3S2 increased from 9.04 percent at 85 percent speed to 13.6 percent at 105 percent speed.

Because of fabrication tolerances, the measured average running clearance was 0.037 cm (0.014 in.) for the 3S1 compressor and 0.043 cm (0.017 in.) for the 3S2 configuration.

Plots of efficiency and pressure ratio versus corrected flow, efficiency versus pressure ratio, and temperature ratio versus corrected flow are presented for both compressors at 85, 100, and 105 percent of design speed in Figures 10 through 27. These plots display all of the performance program and deterioration check run data points. The scatter in efficiency measurements can be seen to be generally within ±0.35 percentage points. No deterioration of performance was noted for either the 3S1 or the 3S2 compressor.

TABLE III

OVERALL PERFORMANCE SUMMARY

	3S1		3S2	
	Test	Design	Test	Design
Inlet Corrected Flow, kg/sec	4.28	4.30	4.35	4.30

Average Tip Clearance/ Average Chord	0.0112	0.0101	0.0199	0.0154

STAGE STATIC PRESSURE CHARACTERISTICS

Comparison Between 3S1 and 3S2 Compressors

The stage static pressure coefficient versus flow coefficient curves presented in Figures 28 and 29 display significant differences between the two compressors. The second and third stage of the 3S1 compressor produced about 10 percent greater peak pressure coefficient at design speed than the corresponding stages of the 3S2 compressor. This greater peak pressure ratio appears to be the source of the higher surge margin of the lower aspect ratio design. The first stage of 3S1 peaked prior to surge and differs from the other lower aspect ratio stages in that respect. The second and third stages of each compressor were subjected to more representative multistage conditions and should be more indicative of the performance potential for their respective aspect ratios in a multistage environment. All stages tested fell away slightly from their design pressure rise as surge flow was approached, but the extremely peaked nature of the first 3S1 stage characteristic suggests that it might be improved by rematching.

The 3S1 and 3S2 rotor characteristics are shown in Figure 28 through 33 for 85, 100, and 105 percent speed. The 100 percent speed characteristics of the 3S1 rotors and stages, Figure 28, are similar in shape and in relative level trends. The prematurely peaked first rotor appears to be the cause of the stalled first-stage characteristic. The second- and third-stage characteristics are below design level, possibly due to poor inlet conditions from the first stage, but closely follow the design shape. The first two 3S2 rotors, Figure 29, follow their respective stage design characteristic trends quite closely, but the last rotor shows a more vertically sloped pressure rise than either its design characteristic or the test characteristics of the other two stages. After the test it was discovered that the stator 3 leading edge static pressure tap used to determine the static pressure rise of the last stage rotor was located inside the vane row. It was concluded that this tap was measuring part of the stator pressure rise, producing excessively high values. The agreement of the three stage characteristics and the first and second rotor characteristics with design, and the mislocated static pressure tap makes it safe to assume that the third 3S2 rotor was also close to design.

Rotor and stage performance at 85 and 105 percent speed, Figures 30 through 33, shows the same trends as in the 100 percent speed results for both compressors.

Compressor 3S1 Characteristics Compared With Design

The static pressure-rise characteristics of the 3S1 compressor are compared with design values in Figures 28, 30 and 32 at 100, 85 and 105 percent design speed, respectively. The first stage is ten percent below its design peak pressure rise while the other two stages come close to meeting their design goals, but at a lower flow coefficient. This falloff of characteristic relative to design but eventual attainment of design level at lower flow coefficient implies an increase in blockage which delays the achievement of peak pressure level. The characteristic shapes for all three stages agree well with design from the highest flow point to the peak efficiency point (fifth data point from surge).

Compressor 3S2 Characteristics Compared With Design

The static pressure-rise characteristics of the 3S2 compressor are compared with design values in Figures 29, 31, and 33 at 100, 85, and 105 percent of design, respectively. All stages are close to their design intent at flows from wide open to peak efficiency (fourth point from surge) at all speeds. At flows below peak efficiency, however, the pressure characteristics are 'ow and prematurely peaked by the same amount relative to design in all three stages at all speeds. These data also show that although premature surge occurred at all speeds tested, all three stages appear to have surged/stalled at about the same time.

The weak first-stage characteristic, relative to the second and third stages, exhibited in the 3S1 test is not present in this uniform 3S2 result, but the peak pressure rise deficit in all three stages of the 3S2 produced significantly less surge margin.

SPANWISE PROFILES

Comparison of 3S1 and 3S2 Spanwise Profiles

Spanwise profiles of pressure ratio, temperature ratio, and efficiency indicate that an increased loading design at reduced aspect ratio flattens discharge radial pressure and temperature profiles and decreases endwall losses. Circumferentially mass averaged discharge radial profiles are shown for peak efficiency in Figure 34. The efficiency of 3S1 was improved in the endwalls, but the improvement was offset by a decrease in core-flow efficiency. Compared with 3S2, the 3S1 lower aspect ratio compressor showed an improvement of 2.4 percentage points in efficiency at the inner wall, a 0.4 percentage point improvement at the outer wall, and a decline in efficiency of 4.0 percentage points at 50 percent span.

Discharge profiles for the 3S1 compressor were significantly flatter than those of the higher aspect ratio compressor. The efficiency profiles of 3S2 was 11.5 percentage points greater at midspan than at the inner wall. In contrast, the efficiency of 3S1 varied by only five percentage points from midspan to either wall. In temperature profile, 3S2 varied about twice as much as 3S1 over the same spanwise extent. In pressure, while the magnitude of the spanwise variation was similar, the shapes were different. The pressure profile of the lower aspect ratio compressor, 3S1, was flat between 20 and 80 percent span while the profile of the higher aspect ratio compressor, 3S2, was peaked in the center.

At near surge, the exit profiles for both compressors tended to flatten and show more similarity than at peak efficiency, as shown in Figure 35. These data indicate that 3S2 demonstrated less root temperature rise near surge than at peak efficiency.

The flatter exit profiles for the 3S1 compressor at peak efficiency, and for both compressors as they were throttled toward surge, indicate that secondary mixing was taking place. The increase of this effect with longer chord and increased loading corresponds to classical secondary loss theories. The increased endwall efficiency with lower aspect ratio could be due to the transport of low momentum air to the depressed efficiency core. However, further testing is required to ascertain whether this core efficiency drop is an inherent efficiency penalty of low aspect ratio blading or a recoverable matching effect.

The slight waviness of the spanwise profiles in Figures 34 and 35 was caused by circumferential variations in the pressure and temperature, which were sampled by the 4 and 5 element probes used to form one composite spanwise profile. Although previous testing been determined that the instrumentation used accurately measures average performance, its use was not intended to produce high resolution circumferential and radial information.

Inlet pressure and temperature profiles at peak efficiency and near surge for both compressors are compared in Figures 36 and 37, respectively, and indicate no significant differences in inlet conditions between the two tests. Tabulations of additional spanwise inlet and exit pressure and temperature data for 3S1 and 3S2 compressor are presented in Appendix "C". These data are for performance points at 85, 100, and 105 percent speeds, being representative of the six repeated speed lines at each speed.

SUMMARY OF RESULTS

Two three stage compressors, representative of the rear stages of advanced compressors, were tested to evaluate the effect of blade aspect ratio on aerodynamic performance. The design aspect ratio of both blades and vanes was 0.81 for the compressor designated 3S1 and was 1.22 for the compressor designated 3S2. The test produced the following principal results.

1. The 0.81 aspect ratio compressor demonstrated 12 percent higher surge margin but 0.9 percentage points lower efficiency than a 1.22 aspect ratio compressor of similar design.

2. The lower aspect ratio compressor had higher efficiency in the endwall regions and flatter spanwise exit pressure and temperature profiles than the higher aspect ratio compressor.

3. The lower aspect ratio compressor exceeded its design surge margin goal by nine percentage points while the higher aspect ratio compressor was three percentage points low. This suggests that improved efficiency may be attainable at the lower aspect ratio by utilizing the demonstrated excess surge margin to redesign for a higher pressure ratio. In addition, the observed poor match of the first stage could be improved.

4. A secondary flow mixing process, which transports low momentum fluid from the endwall region to the core flow regions and is enhanced by increased chord and loading, could be responsible for the flattening of the profiles of 3S1 and both the increased endwall region efficiency and decreased midspan efficiency of 3S1 relative to 3S2. This mechanism could also explain the profile flattening for both compressors as surge is approached.

DATA REDUCTION EQUATIONS

DATA CORRECTION AND MASS AVERAGING

All measurements were corrected to the nominal test speed and NASA standard sea level inlet total pressure and temperature. Exit total temperature and pressure data at each radius were corrected using the relationships:

$$(1)\quad T_o = K_T \left\{ 1 + \left[\frac{T_{o,\ test}}{T_{o,\ inlet\ (mass\ av)}} - 1 \right] \left[\frac{N_{cor,\ nom}}{N_{cor,\ test}} \right]^2 \right\}$$

$$(2)\quad P_o = K_P \left\{ 1 + \left[\left(\frac{P_{o,\ test}}{P_{o,\ inlet\ (mass\ av)}} \right)^{\frac{\gamma-1}{\gamma}} - 1 \right] \left[\frac{N_{cor,\ nom}}{N_{cor,\ test}} \right]^2 \right\}^{\frac{\gamma}{\gamma-1}}$$

where, K_T = 288.15K (518.69 °R)
K_P = 10.1325 X 10^4 N/m^2 (2116.22 lbf/ft^2)

Static pressures measured at the inner and outer case walls were corrected to ambient level using the relationship:

$$(3)\quad P = K_P \left\{ \frac{P_{test}}{P_{o,\ inlet(mass\ av)}} + \frac{2\gamma}{\gamma-1} \left[\left(\frac{P_{test}}{P_{o,\ inlet\ (mass\ av)}} \right)^{\frac{\gamma-1}{\gamma}} - 1 \right] \cdot \left(\frac{P_{test}}{P_{o,\ inlet\ (mass\ av)}} \right)^{\frac{1}{\gamma}} \left[\left(\frac{N_{cor,\ nom}}{N_{cor,\ test}} \right) - 1 \right] \right\}$$

where Mach number squared has been assumed small with respect to 1.0. The compressor inlet total pressure and temperature measurements were mass averaged radially and circumferentially for each test point in order to obtain the reference values in equations (1), (2), and (3). Corrected test speed, defined by $(N/\sqrt{\theta})_2$, was also obtained for each point.

The levels of inlet total pressure and temperature measurements were adjusted so that the radial and circumferential mass averages of all readings are equal to the standard values.

(4) $P_o = K_P + P_o - P_o$ inlet (mass av)

(5) $T_o = K_T + T_o - T_o$ inlet (mass av)

The corrected test values for total temperature and total pressure from the pole rakes at the inlet and exit stations were circumferentially and radially mass averaged to produce average values for calculating overall performance. A linear static pressure gradient between inner and outer cases at each circumferential location was used for the mass averaging. The corrected data were also mass averaged circumferentially at each radius to give composite radial distributions of temperature and pressure at the inlet and exit stations.

Compressor Overall Performance Computations

Pressure Ratio

Since the tests were intended to reproduce conditions which would be present in the latter stages of a core compressor, the overall performance was presented from upstream of the first rotor (station 2 of Figure 1) to the exit station (station 9). The overall pressure ratio based on the inlet to the first rotor was calculated as follows:

$$\frac{\bar{P}_{09}}{\bar{P}_{02}} = \frac{\bar{P}_{09}}{\bar{P}_{01}} \times \frac{1}{\bar{P}_{r,IGV} \times \bar{P}_{r,pole} \times \bar{P}_{r,strut}}$$

where $\bar{P}_{09}$ = exit station mass-averaged total pressure

$\bar{P}_{02}$ = first rotor inlet mass-averaged total pressure

$\bar{P}_{01}$ = inlet station mass-averaged total pressure

$\bar{P}_{r,IGV}$ = total pressure ratio across the inlet guide vane

$\bar{P}_{r,pole}$ = total pressure ratio due to losses of inlet station and flow station pole rakes

$\bar{P}_{r,strut}$ = total pressure ratio due to inlet strut losses

All the inlet loss pressure ratios were calculated as functions of the inlet dynamic pressure calculated as a function of flow by:

For W_{cor} in kg/sec

$$\frac{P_o - P}{P_o} = 1.682842 \times 10^{-3} + W_{cor} \times (2.083418 \times 10^{-3}\, W_{cor} - 1.455674 \times 10^{-3})$$

For W_{cor} in lbm/sec

$$\frac{P_o - P}{P_o} = 1.682842 \times 10^{-3} + W_{cor} \times \left(4.28655 \times 10^{-4}\, W_{cor} - 6.602824 \times 10^{-4}\right)$$

$$\overline{P}_{r,IGV} = 1.0 - 0.01534 \left(\frac{P_o - P}{P_o}\right)$$

$$\overline{P}_{r,pole} = 1.0 - 0.035095 \left(\frac{P_o - P}{P_o}\right)$$

$$\overline{P}_{r,strut} = 1.0 - 0.001455 \left(\frac{P_o - P}{P_o}\right)$$

Temperature Ratio

Since no work is done ahead of the first rotor and heat loss through the cases is estimated to be negligible, the total temperature ratio is unchanged:

$$\frac{\overline{T}_{09}}{\overline{T}_{02}} = \frac{\overline{T}_{09}}{\overline{T}_{01}}$$

Adiabatic Efficiency

The adiabatic efficiency of the compressor was calculated by:

$$\eta_{ad} = \frac{\left(\overline{P}_{09}/\overline{P}_{02}\right)^{\frac{\gamma-1}{\gamma}} - 1.0}{(\overline{T}_{09}/\overline{T}_{02}) - 1.0}$$

where γ = the ratio of specific heats at the average temperature of the compressor.

Flow Rate

The flow rate was first calculated for the inlet flow calibration station (station 0) and then corrected to the inlet of the first rotor (station 2). An ideal flow rate was calculated from the average midspan total pressure measured at the flow calibration station, the average midspan static pressure at that station (obtained by linear interpolation between outer and inner wall measurements), and the mass averaged total temperature from all the measurements at station 1. The actual flow rate was then the product of the ideal flow rate and the flow coefficient. Thus

$$\left(W \frac{\sqrt{\theta}}{\delta}\right) = (W_{IDEAL}) \times (\text{Flow Coef.}) \frac{\sqrt{\dfrac{\bar{T}_{01}}{K_T}}}{\left(\dfrac{\bar{P}_{02}}{K_P}\right)}$$

Rotor and Stage Performance Based on Wall Static Pressures

Rotor and stage performance was computed separately for each of the three stages for each test point in terms of a static pressure rise coefficient and a flow coefficient. The static pressure rise coefficient is based on the kinetic energy the midspan flow would have if the air velocity were the same as the rotor velocity. The rotor static pressure rise coefficients are:

$$\psi_{\text{ROTOR 1}} = \frac{P_3 - P_2}{\dfrac{1/2 \quad \rho_2 \quad U_{m2}^2}{g}}$$

$$\psi_{\text{ROTOR 2}} = \frac{P_5 - P_4}{\dfrac{1/2 \quad \rho_4 \quad U_{m4}^2}{g}}$$

$$\psi \text{ ROTOR } 3 = \frac{P_7 - P_6}{\dfrac{1/2 \;\; \rho_6 \;\; U_{m6}^2}{g}}$$

where P = static pressure, N/m^2 (lbf/ft^2)

ρ = fluid density, Kg/m^3 (lbm/ft^3)

U_m = midspan rotor speed, m/sec (ft/sec)

and subscripts for P, ρ, and U_m correspond to station numbers in Figure 5.

Similarly, the stage static pressure rise coefficients are:

$$\psi \text{ STAGE } 1 = \frac{P_4 - P_2}{\dfrac{1/2 \;\; \rho_2 \;\; U_{m2}^2}{g}}$$

$$\psi \text{ STAGE } 2 = \frac{P_6 - P_4}{\dfrac{1/2 \;\; \rho_4 \;\; U_{m4}^2}{g}}$$

$$\psi \text{ STAGE } 3 = \frac{P_8 - P_6}{\dfrac{1/2 \;\; \rho_6 \;\; U_{m6}^2}{g}}$$

The flow coefficient used for both rotor and stage performance is the ratio of the axial velocity at the rotor inlet station to the midspan rotor speed.

$$\phi 1 = \frac{V_{z2}}{U_{m2}} ,$$

$$\phi 2 = \frac{V_{z4}}{U_{m2}} ,$$

$$\phi_3 = \frac{V_{z6}}{U_{m6}}$$

In order to calculate the fluid density values, the pressures and temperatures within the compressor were calculated based on assumptions of equal rotor pressure ratio and temperature ratio for each stage. Stator losses were assumed equal to the design values for every test point.

$$\bar{P}_{r,ROTOR} = \frac{\bar{P}_{03}}{\bar{P}_{02}} = \frac{\bar{P}_{05}}{\bar{P}_{04}} = \frac{\bar{P}_{07}}{\bar{P}_{06}}$$

$$= \left[\frac{\bar{P}_{09}/\bar{P}_{01}}{\dfrac{\bar{P}_{02}}{\bar{P}_{01,DES}} \times \dfrac{\bar{P}_{04}}{\bar{P}_{03,DES}} \times \dfrac{\bar{P}_{06}}{\bar{P}_{05,DES}} \times \dfrac{\bar{P}_{08}}{\bar{P}_{07,DES}}} \right]^{1/3}$$

$$\bar{T}_{r,ROTOR} = \bar{T}_{r,STAGE} = \left(\frac{\bar{T}_{09}}{\bar{T}_{01}} \right)^{1/3}$$
